CHARGES and counter-charges of an excessive use of money for campaign purposes are being made by both political parties, thereby continuing the exposures that were started before the meeting of the conventions at Chicago and San Francisco. The facts will disgust the public and tend further to decrease interest in a presidential campaign that so far has evoked but scanty enthusiasm, largely because neither nominee commands admiration. Senator Harding states that the millions collected by Messrs. Upham and Hays for the Republican cause "are essential to our success in planning for national enlightenment and are all deeply appreciated by me". Why not say, in the best front-porch manner, that they are "essential" to the "evolvment" of "normality". A bitter fight is looming, and in the course of it we expect to see Governor Cox's war record exposed. Through his newspaper he expressed opinions that are thoroughly discreditable. For ourselves, we wish that the vice-presidential candidates were on the same ticket and could be elected in lieu of their leaders.

PRAISEWORTHY co-operation and a spirit of fair-dealing on the part of miners, mine-operators, and members of the Industrial Accident Commission of California has resulted in the formation of a set of Mine-Safety Orders that is definite and complete, and that affords reasonable protection to workmen without imposing impracticable and unworkable restrictions on the companies owning mines and metallurgical plants. In 1915 the Commission adopted mine-safety rules, which have lately been revised by a committee composed of mine-operators and sundry officials from organizations of mine, mill, and smelter employees, who, upon invitation, collaborated with the engineers of the Commission. As a result, a tentative draft of the new orders was printed and distributed among those connected with the industry, and last week a public hearing was held to receive any protest or criticism before the final form of the orders should be determined. One proposal directed that stoping should be done in such a manner that the back at any time could be tested, either from timbering or broken rock, with a seven-foot bar. It was pointed out at the hearing not only that this was sometimes impracticable, but that, for instance, in some stopes where shrinkage methods are employed, additional ore is drawn

off for the specific purpose of preventing accidents. The Commission accordingly will amend the regulation so as to permit its engineers to determine the procedure according to the methods and conditions in particular mines. Another proposal fixed five years of practical experience underground as one qualification for a mine superintendent. It was recommended that this be changed to three years for a superintendent employing more than 25 men, and two years where less than that number is employed. Apparently, the policy of the Commission is to avoid making orders that are unreasonable or unjust; a natural corollary would be insistence on strict compliance with the regulations that are made; laws that are not enforced are worse than no laws at all.

The Struggle at Rio Tinto

On July 8 began the greatest strike in the history of Rio Tinto, the famous copper mine in Spain. The property has been involved in a sort of perennial labor-war for several years, with brief intervals of peace. In the beginning the agitation was provoked by German agents in order to hinder the output of copper and pyrite for the Allies. The Red variety of socialist was employed by Germany in this work, not only at Rio Tinto but throughout Spain. Syndicalism was developed with the thoroughness and finish so characteristic of German economic institutions, for the principle of completeness serves destructive as well as constructive purposes. It was the masterly devilishness of this highly perfected anti-social organization, bearing the brand 'Made in Germany', that plunged Mr. Frank A. Vanderlip into a panic of post-prandial panegyrics upon Spain and the Spanish people while he stood upon the volcano of Spanish terrorism in Barcelona, although he promptly substituted a deluge of diatribe as soon as he had passed safely beyond the border.

Spanish syndicalism is startling to one who is unaccustomed to the red torch with which Germany has lighted the social conflagration in Europe. It has been met by measures less oppressive than we would deem warranted in this country under like provocation, but the preparations to combat a general uprising are more elaborate than appear upon the surface. Nevertheless, the Rio Tinto strike, involving 10,000 workmen, quickly followed by the strike of iron and steel workers at Bilbao, where 40,000 men have made a determined stand against the authorities, surpasses any demonstration that has been witnessed previously in the Peninsula. Agitation against the Rio Tinto Company has enjoyed a certain popularity throughout the country, which undoubtedly has facilitated the propaganda of the syndicalists. Like all government-owned mines, the Rio Tinto was an incubus upon the State for generations; it was operated at a loss, just as the famous Arrayanes lead mine at Linares has always been a failure, and as the Almaden quicksilver mine shows a deficit, in any period of five years, despite its marvellous orebodies with their fabulous tenor of 8% of mercury. Accordingly, the Rio Tinto was sold to an English company in 1872, and after a long financial

struggle, involving the investment of enormous capital, it was placed firmly in the position of a steady producer of profit, the gross amount of which appears stupendous in the eyes of demagogues. It is the fashion, therefore, when less urgent matters demand attention, to rail at the opulent Rio Tinto Company, which is accused of despoiling Spain of her resources.

The strike started as usual with the workmen employed in the smelter, which is the smaller part of the Rio Tinto operations. In two days the entire enterprise was paralyzed, even the railroad men and telegraphers joining the strike. Communication with the port of Huelva was maintained by running a mail-train manned by members of the English staff. The cessation of traffic, on which the town depended for the necessities of life, immediately brought the population face to face with famine. A committee of women appealed to the manager, Mr. Walter J. Browning, to make concessions to the workmen in order to avert starvation. He refused to be coerced by sympathy, and told them to send their husbands back to work, but to each visitor he gave five pesetas (\$1) as a gratuity. The local authorities then petitioned the Council of Ministers at Madrid, which resulted in a request from the Governor of Huelva to the president of the workmen's syndicate for a proposal that might serve as a basis for discussion with the Rio Tinto Company. The reply was an insistence upon recognition of the union and the syndicate, following which terms of settlement would be offered. This was repudiated, but it is interesting to note that at this juncture a movement for conciliation took place within the ranks of the strikers. Although it was stopped by the labor leaders, it possesses significance. For many months before the outbreak of the trouble, rumors of an impending crisis had been coming to the United States in the form of letters from conservative workmen begging an opportunity for employment here, alleging that they were being coerced by the radical element under non-Spanish influences, and, being unable to resist this pressure, they were eager to escape before the storm should break. Their idea was to settle in a country where they could do an honest day's work for an honest day's wage and rear their families in peace. This episode indicates that there exists a rational element, around which, as a nucleus, a loyal body of workmen may be built. The problem there, as well as in the United States, is to get rid of the foreign agitators.

The Government next appointed Señor Leopoldo Palacios, of the Instituto de Reformas Sociales, a branch of the public service presided over by the distinguished sociologist, Señor Adolfo Posada, to make an effort to effect a compromise. This brought out concrete demands from the union that embraced reinstatement of all striking workmen, pay for time lost during the strike, regulation of pensions and contributions for medical and other benefits, and an increase of 50 to 65% in the wages paid. Mr. Browning proposed an increase of three reales (about 15 cents) on all wages from three pesetas upward, a doubling of all wages below three pesetas, and some minor concessions. The deadlock was complete, and Señor Palacios retired, admitting his inability to settle the

dispute. Meanwhile seven steamships that had been chartered to load pyrite at Huelva were obliged to sail in ballast, and a steady emigration of laborers from Rio Tinto began. Hundreds of men have deserted the mine, avowing their determination never to return. These include many of the most capable and reliable, so that the preponderance of the radical type is increased, which will augment difficulties in the future. The union insists that this must be a conclusive contest, and evidently the company has accepted the gage of battle. To surrender now would mean ceaseless heckling and practical dictation by the agitators, which would render economic operation impossible. It is an unfortunate moment for the miners at Huelva, owing to the rapid increase in the competition of brimstone as a basis for sulphuric-acid manufacture. The American demand for pyrite has fallen enormously with the general change to sulphur-burning at the acid-works in this country. The purity of the acid made from brimstone as compared with the acid made from pyrite, which always contains some arsenic, is raising the standard and giving the advantage to the sulphur producers of Louisiana and Eastern Texas. In the face of a diminishing American market for Spanish pyrite, the syndicalists have chosen an inopportune time to make demands that would increase the cost of producing ore at Rio Tinto. The wages paid have been low, but they were on a par with those prevailing in other parts of Spain. To ameliorate the hardships of the workers without setting new standards of compensation, the Rio Tinto Company has long been selling supplies at a loss through its fourteen stores, undertaking in this manner to sustain the resources of the laboring men in the face of rising prices. For example, the company stores have been selling a daily average of 40,000 pounds of bread at a loss of 26% on the cost price, 400 gallons of olive oil at a loss of 23%, 2200 pounds of sugar at a loss of 33%, and other articles in proportion. The wholesale price of flour in Spain on July 1 was at the rate of 10 cents American per pound, sugar sold for 26 cents, beans for 4 cents, rice for 7½ cents, and olive oil for \$1.25 per gallon. In addition to the consideration shown in supplying the prime necessities below cost, the Rio Tinto Company has built model villages of commodious houses, in which every modern sanitary convenience has been provided, and these houses are rented to workmen at less than the cost of crowded unhealthy quarters in the manufacturing towns. The better class of laborers have seemed content with the conditions, and have asked only that they be freed from the agitation of the Red leaders, but the present struggle has led to an impasse that will embitter the people for a long time to come. They have been led to believe that the attitude of the manager has not been sanctioned by the board of directors in London, and that he is personally hostile. Intense excitement was produced by a report that Mr. Browning intended to shut off the water-supply from the town and was prevented from doing so only by the intervention of the local political authorities. He is also blamed for the suspension of freight deliveries, regardless of the fact that the railroad operatives have joined the strikers. The Spanish view of the situation at

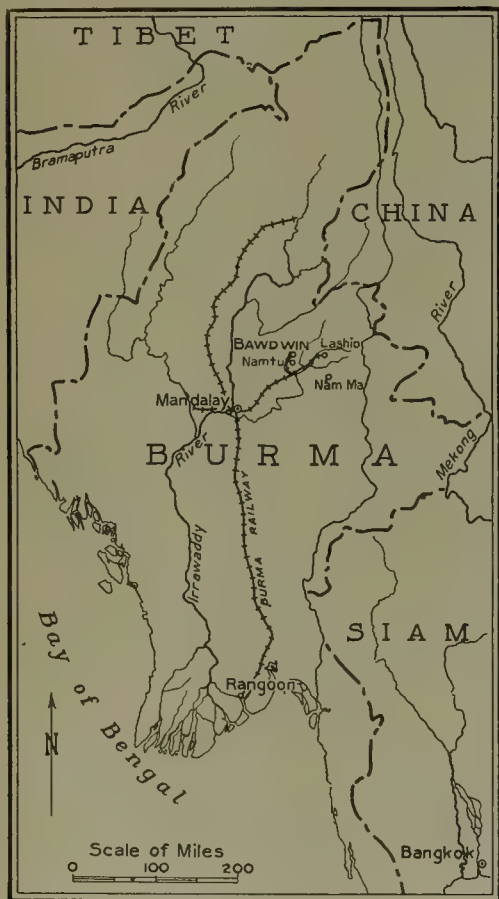

Rio Tinto before the outbreak of the strike has been presented in a novel entitled 'The Metal of the Dead' by Concha Espina, one of the most talented writers of the country, a book that has just been published. It will help to reveal the serious problem faced by the Rio Tinto Company, which in some respects is national, if not, indeed, international.

The Burma Corporation

In these days when entire mountains are being carried piecemeal to leaching-plants and concentrators, a mine with an ore-reserve of 4,732,003 tons is no longer astonishing. If, however, in addition to 1.2% of copper, in itself enough to promise profitable exploitation under favorable conditions, the ore contains an average of 18.2% zinc, 26.4% lead, and 24.5 ounces of silver per ton, the total of 4,732,003 tons becomes an impressive quantity. If only 80% of the metal contents of this ore were recovered and sold at the present market prices, the proceeds would amount to nearly 500 million dollars. These figures, except for the calculation as to the estimated value of the metals, are found in a recent report by Mr. John A. Agnew on the operations of the Burma Corporation, Ltd., in Upper Burma. In our issue of November 29, 1919, we reviewed the history of this remarkable enterprise. In December 1919 a new company was incorporated at Rangoon with a capitalization of 20,000,000 shares, of 10 rupees each, together with £1,000,000 of 8% convertible stock, the purpose of the latter being to provide funds for the completion within three years of the metallurgical plants, power-projects, and railroad construction necessary to treat 1650 tons of high-grade ore daily. The present earnings of the company are at the rate of £600,000 per year, and since £1,600,000 will suffice to carry out the proposed construction and equipment, it is apparent that before long the current profit should be available for dividends. The decision of the National Mining Corporation to underwrite the stock-issue was based on the report of Mr. Agnew. It is a clear and concise analysis of the resources of the company and of the methods by which it is proposed to exploit them, together with an estimate of the financial results to be expected. Mr. Agnew disclaims any superiority of judgment as to the trend of future prices for metals but presents comprehensive tables showing how the profit will be affected by fluctuations above certain prices which he thinks may safely be assumed as the minimum. These are, lead at £22, spelter at £33, copper at £80, per ton of 2240 pounds, and silver at 40 pence per ounce. In American currency, taking the pound sterling at \$4.50, these prices are equivalent to 4.42, 6.63, 16.07 cents per pound, and 75 cents per ounce, respectively. The company has recently acquired a new lease for 30 years from the Indian government on the ten square miles of ground that includes the mine at Bawdwin. The geology of the area is discussed briefly; the statement is frankly made that "it is to be expected that if the ore-channel passes into sediments in depth the orebodies will become restricted in size". This is in accord with experience elsewhere. Thus far, development

has been confined largely to lateral work from the Tiger adit, which is the bottom level, and the two levels immediately above. For the purpose of estimating the ore in reserve, an additional zone only 100 feet in depth is assumed as containing 'probable' ore, although this should not be interpreted as delimiting the orebodies. About 1,600,000 tons of lower-grade ore is proved, but nothing is included in the calculations that does not contain at least 20% of combined lead and zinc. At present the mine is in condition to produce 1500 tons of lead-

visited Burma as consulting engineer. After a number of possible plans had been considered, it was decided on his recommendation to construct an entirely new and modern smelter near the mill at Namtu, rather than attempt to remodel the old plant, and to build a retort-smelter and sulphuric-acid plant at Jamshedpur, near Calcutta, to treat annually 25,000 tons of zinc-concentrate. The proposed site adjoins the famous plant of the Tata Iron & Steel Co., which will utilize in its galvanizing department a large proportion of the zinc produced. Both these projects are now under way. There is still doubt as to the metallurgical plan to be adopted finally, but the alternatives as stated by Mr. Agnew, and on which he bases three separate estimates of resultant realization, are interesting. The first, a 'foul-smelting' scheme, involves nothing new. The concentrator will produce a zinky lead-concentrate, a zinc-concentrate, and a middling. The first will be smelted for lead, the resulting zinky slag being treated with the middling in a reverberatory furnace, while the zinc-concentrate is sent to the retort-smelter in India. The other schemes provide for two clean concentrates, one of lead and one of zinc, to be made in the mill and sent to the appropriate smelters, while a comparatively large proportion of middling, containing less than 30% lead and 30% zinc, will be treated by either the 'double chloride' or the Elmore process, yielding a lead bullion and a clean, and accordingly desirable, zinc-concentrate for shipment to Jamshedpur. The process would be simplified by making not more than two products in the concentrator in addition to a clean tailing. These would be a high-grade lead-concentrate and a middling, containing nearly all the zinc and some lead, which would then be treated by one of the proposed chemical processes in order to obtain a clean zinc-concentrate for the retort-smelter, besides lead and silver ready for refining. The treatment will probably develop in this direction because it promises profit considerably in excess of that assured by foul smelting. It may be remarked that no electrolytic process is being considered; one reason for this is the lack of an adequate supply of hydro-electric power, although the company will generate a dry-season minimum of 1250 horse-power at Mansaw falls. In addition, a 2500-kilowatt generating station is to be built at Nam Ma, where the company's geologists have discovered a deposit of semi-bituminous coal of good grade. Approximately 7,000,000 tons has already been proved; this will replace the almost exhausted supply of wood for fuel at the smelter as well as operate the steam-electric plant. The development of this coal was one of the factors that determined the selection of Namtu as the site of the new smelter. Thus far the stockholders of the corporation have received no dividends, all the current profit having gone into construction and betterments. This remarkable mine has had the benefit of intelligent engineering and sound financing. There is every reason for believing that Mr. Agnew's calculations, based on the estimates of Mr. R. G. Hall, the resident manager, are conservative and that a profitable future is assured.

zinc ore and 150 tons of copper ore per day, so that development work will be directed mainly to blocking out additional ore while supplying the current needs of the existing plants. The ore itself is a complex mixture of sulphides of lead, zinc, copper, and iron. The silver is associated with the lead and copper, in proportion to these metals and irrespective of the zinc content. The fineness of the particles and the intimacy of the mixture of galena and blende present obstacles to metallurgical treatment. The existing plants include a smelter, which has been treating high-grade lead ore, at Namtu, 13 miles from Bawdwin, since 1911, and a new concentrator, with a present capacity of 800 tons per day, which since being started recently has supplied lead-concentrate instead of raw ore to the smelter. In 1918 Mr. Lawrence Addicks

DISCUSSION

Engineering Education

The Editor:

Sir—Acting upon the editorial invitation in your issue of August 14 to discuss engineering education, I submit with much humility my own poor views upon the subject. This apology is necessary because, otherwise, someone might think that I imagine educators reading this letter will be influenced by it, which I don't. (This is nearly as complicated as Harding's front-porch effusions.) Few high-ranking educators will accept your invitation, I think, and discuss the matter freely, because they realize that they disagree markedly among themselves, and it is a mark of honor in the teaching profession to suggest no changes of any importance—merely small fads that don't disturb things too much.

I would summarize my personal views as follows:

(1) A four-year course, as you suggest, is enough. Employers in all lines of engineering prefer a man not too specialized who will adapt his ways to theirs; and, as Dr. Mann in his famous report has pointed out, technical ability is only a small portion of what an employer looks for in the young engineers. Six years gets a student in a rut.

(2) Engineering courses should be less technical and more cultural. This could be gained by eliminating much highly-specialized technique, as now taught, and making courses broader and more leisurely, so that the hard-pressed student could look around a bit and read on his own account. Milo S. Ketchum, from his long experience in engineering education, has remarked that the cultural value of a course lies more in the teacher than in the subject matter. For my part, I picked up more culture from a course in steam-engineering given by O. P. Hood than from various courses in English literature and public speaking. However, engineering courses will not be made less technical and more cultural for a long time, because to do so would make it necessary to throw out of their jobs many unchangeable professors who are long on technique and short on culture. O. P. Hood himself left teaching to work for the Bureau of Mines.

(3) Quoting Milo S. Ketchum again, the problems of engineering education will be largely solved when better teachers are secured. Improvement will come not so much by mechanical changes in courses, or new wrinkles in this or that, as by getting capable men to serve as professors with not too much restriction on their individuality. And, of course, they should be well paid. Otherwise professors like O. P. Hood will leave the profession. Again, I do not think this reform will come about, at least for some time. Too many poor teachers are in

already, and they protect their interests by keeping capable men out, for which perhaps no one can blame them. Also there is too much machinery, using the word in the figurative sense, in the conduct of the colleges—too much red tape, too much ponderousness to overcome to change anything, too many committees for regulating what generally should be left unregulated in order to give scope for individuality.

Of course, changes will come in engineering education. They are taking place all the time, but they get so compromised and complicated by the time they become effective that they become something else in the meantime.

P. B. McDONALD.

New York University, August 19.

Concerning Silver

The Editor:

Sir—Mr. Charles Butters concludes his letter concerning silver, published in your issue of August 7, by saying: "If any reader can tell me on what grounds the Mint can insist on paying for silver deposits in gold when the depositor of bullion asks for silver, I shall be very glad to learn."

Previously, in his letter, he had written: "Now I will tell you just what happens right now, because it happened to me. You go to the Mint with your fine bars and ask them to coin them at the market price. The reply is 'Yes, but we pay you in gold. We are not letting any silver out at present. We want the silver to get back our reserves'. It is a curious attitude."

In your issue of July 31, I had noticed a 'personal' to the effect that Mr. Butters was on his way here; so, after reading his letter, I called at his office, hoping to have the pleasure of meeting him once more and, incidentally, to inquire if he meant his letter to be taken seriously or whether it was intended to be a sort of pleasantry. Much to my regret, I learned he had remained but a few days and was then in Mexico. Consequently, with your kind permission, I will endeavor to reach him through the medium of your columns.

Perhaps I have missed the real meaning that he intended to convey, but, taking the literal interpretation of the words about his visit to the Mint, I am sure either he did not understand correctly what was said to him about paying gold for fine bars, or else he was misinformed. At present, the Mint does not pay out gold for bars of fine silver. Instead, they are paid for in paper currency or by check (or draft) on the U. S. Treasury; and, in the latter case, which is customary for

larger sums, the word 'silver' is written on one corner of the check as a notice that it has been issued in payment for silver bullion and that it is to be cashed in current funds. Of course, a given amount in current funds has the same exchange value now as a like sum in gold coin. If we were using a silver standard, instead of gold, Mr. Butters could have obtained silver 'dollars' for his bars of fine silver; but who wants "free silver," anyway?

The precise meaning that Mr. Butters wished to convey by saying, "You ask them to coin them at the market price", seems to be very obscure, because silver is not coined at the market price". To illustrate; suppose he took two bars of fine silver, of 1000 ounces each, to the Mint. If they were domestic silver, he would obtain the "market price" of \$1 per ounce for them; either in the form of a check or in paper currency, according to his choice, for that is the "market price" paid by the Mint. But, if the Mint coined that quantity (2000 oz.) of fine silver into 'dollars', it would produce 2585.858 (1.292929 \times 2000 oz.) such 'dollars'. Therefore, in all probability, he wouldn't expect the Mint to give him that many silver 'dollars' for his 2000 ounces of fine silver, for, by so doing, it would pay him at the rate of \$1.29 per ounce, which is the 'Mint price' for silver that Uncle Sam charges the public when he issues silver 'dollars' to it.

With reference to the statement of the Mint employee that "We want the silver to get back our reserve", it is not so very long since Uncle Sam depleted our reserve to the extent of 207,000,000 oz. of fine silver, to obtain which he melted down something like 267,636,363 silver 'dollars', against which, it is quite probable, silver certificates had been issued; and that quantity of silver was just as far removed from the market, while the silver certificates were in use, as it would have been in the form of silver 'dollars' in actual circulation.

To digress for a moment; it may be said that such of our silver 'dollars' as have been issued have been sold to the public at the rate of 30.02 gr. of gold (\$1.29), or its equivalent, per ounce of fine silver contained in them. And yet Uncle Sam took many of them away from us, giving us Federal Reserve bank-notes in exchange (Federal Reserve bank-notes not Federal Reserve notes) and then sold this silver abroad at the rate of only 23.22 gr. of gold (\$1.00) net per ounce; for which we had paid him 30.02 gr. of gold (\$1.29). The difference is 6.8 gr. of gold per ounce, which, multiplied by 207,000,000 oz., equals 1,407,600,000 gr. of gold; or \$60,620,000 in round numbers. This will be reverted to, herein, later on.

With reference to that paragraph in Mr. Butters' letter that begins with "If our paternal and non-profit-making Mint buys silver for, say, 90c. per ounce and coins it into silver at anywhere between \$1.29 and \$1.38", it is probable that he, upon reflecting, will recall that that difference (\$1.29 or \$1.38 less 90c.) is termed 'seigniorage'. It is really a tax imposed by all gold-standard nations on silver and subsidiary coins. In my communication entitled 'What is a Dollar', which appeared in your issue of August 3, 1918 (a copy of which I gave to Mr. Butters at that time), it was stated, in effect, that, according to a recent article in the local press, the present cost of silver to the Government had averaged 72c. per ounce. Conse-

quently, if the cost was given correctly, the seigniorage (profit) made by the Mint amounted to 57c. per ounce on the silver in the silver dollars and 66c. per ounce on the silver in the subsidiary silver coins. The profit on the 267,636,363 silver 'dollars', alone, would have been nearly \$118,000,000. Hence, the term "non-profit-making" doesn't seem to fit the Mint very well when the latter is engaged in turning out silver coins under the conditions that have obtained during the past generation or so.

To digress once more, Uncle Sam, no doubt, intends to be fair to the public, and, as evidence of such intention, he has said he will endeavor to restore to his Treasury reserves a quantity of silver equal to that which he "borrowed" from the public and sold to foreigners to overcome a very trying situation abroad that had been occasioned by the War. Inasmuch as he sold the public's silver dollars at \$1 per ounce, and, perhaps, because he wants to encourage some of our home industries, he offers to pay the public \$1 per ounce for all it will produce, from home territory, up to 207,000,000 oz. Our production, per annum, has been estimated at about 50,000,000 oz., so the price of \$1 per ounce seems to be fixed for a period of about four years. As has been stated previously, the public, presumably, paid a seigniorage tax of about \$118,000,000 on the 207,000,000 oz. that Uncle Sam borrowed from it. Just now it seems pertinent to ask if the public does dig up out of the ground, during the next four years or so, 207,000,000 oz. of silver, will Uncle Sam, after buying it at \$1, coin it into dollars and sell it back to the public at \$1.29 per ounce, thereby making an additional seigniorage profit of more than \$60,000,000 on silver coin that, practically, has already cost the public a seigniorage tax of \$118,000,000?

The ethics of Uncle Sam's decision to buy domestic silver at \$1 per ounce, rather than purchase foreign silver in the marts of the world at a lower price, will admit of debate; and this is particularly true because the producers of domestic silver will sell it to him at \$1 per ounce only in case they cannot obtain a higher price for it elsewhere. Still, he can afford to pay \$1 per ounce for domestic silver, even if foreign silver is available at a lower price, if he sells it back to the public at \$1.29 per ounce, although he would make more if he bought foreign silver at less than \$1. Or, if he buys and coins the 207,000,000 oz. into silver 'dollars', issues silver certificates against them, and retires a corresponding amount (\$267,636,363) of Federal Reserve bank-notes, will the public be relieved of the additional \$60,000,000 seigniorage tax?

Perhaps one of your readers who is experienced in government finance will answer this conundrum. If not, would it be proper to ask Senator Pittman?

New York, August 14.

W. DE L. BENEDICT.

A CORPORATION has been formed in London, according to an article in 'El Economista', for the placing, in Spanish ports, of stocks of petroleum products. The capital of this corporation is 25,000,000 pesetas (1 peseta = 19.3c., normal exchange), 55% of the stock being held by the 'English Shell' group, the remaining 45% being divided among several Spanish companies in Madrid.

RUINS OF THE MILL AFTER IT HAD BEEN DYNAMITED IN 1899

A MOTOR-TRUCK HAULING MINE-TIMBERS

The Bunker Hill Enterprise—XII

The Human Side of the Business; Labor Troubles; Good Management

By T. A. RICKARD

On September 9, 1919, Mr. Easton and I went up Milo gulch so that I might see the place where the Bunker Hill lode was discovered and get a general idea of the district. This was not my first visit to the locality; I was there in October 1904, on my way from New York as delegate at large to the American Mining Congress at Portland. It was a pleasure to find the mine under the same manager, and, as I said to Mr. Easton laughingly, both looking bigger than ever. Leaving Kellogg, we were soon in the deserted street of the senior settlement, Wardner.

The town of Wardner used to extend for some distance on each side of Milo creek; now it has shrunk to a row of dilapidated and bedraggled houses, most of them untenanted. Those which have disappeared have served for fire-wood and other useful purposes. Their sites and their little 'yards', or gardens, have been re-claimed by Nature. Mr. Easton pointed on the right to the Page hotel, formerly notorious for its wild doings. On both sides of the road are the shells of the 'hurdy-gurdies', 'honky-tonks', dance-halls, and beer-saloons now extinct.

On October 10, 1885, the name of Yreka was given to this mining district, and the town was called Kentuck, but the Post-Office department refused to accept the latter name; so on April 4, 1886, it was changed to Wardner, in honor of Jim Wardner, "a widely known and popular citizen, who did much toward advancing the prosperity of the young but ambitious town". So says the 'History of North Idaho'.

On January 4, 1890, a fire-alarm was followed by the discovery that no water was available; this caused "deepest chagrin", says the chronicler, and compelled "the stricken populace" to fight the flames with snow—successfully, it may be presumed, for the town survived.

On the right is Wardner mountain, in whose rocky depths are the workings of the great mine. Mr. Easton showed me the line of the outcrop, now obscured by the brush that has grown on the rock broken in the course of prospecting. In the gulch is the dump and entrance of the Reed tunnel, the first adit of the Bunker Hill mine and named after Simeon Reed, who bought it from its discoverers. There was the upper terminal of the Bleichert tramway, which crossed the town of Wardner in a 1700-ft. span and in its time was one of the biggest things of its kind. All the old photographs show the tramway, which united the Reed adit with the concentrator that was built near the present mill-site. When the Kellogg adit was completed, in November 1902, the use of the tramway was discontinued. These old workings

in Milo gulch are still in use, all the ground above the Reed tunnel being under lease to various parties of 'tributers'. At the time of my visit 80 of these lessees were at work. A million tons of ore has come out of the Reed tunnel. At the entrance is the old candle-house where illuminants were issued to the miners; now the

IN THE COEUR D'ALENE

acetylene lamp is in general use. Thirty years ago a miner required three candles per shift, at a cost of 6 cents apiece; now the carbide used in his lamp costs only 3½c. per shift. The lamp itself costs \$1.30 and lasts from two to six months, according to the care it receives. Most of the old Reed mill is dismantled, but out of the remnants a party of lessees has made a rough concentrator and is treating 80 tons per day. Those of us who have been managers of mines know the genus 'tributer', or 'leaser', as he is often incorrectly labeled, and will

appreciate this story: A local soothsayer, called Alexander, was asked by one of them: "Will I make any money out of my lease?" The oracle replied: "If you'll go up there and work steadily, instead of spending so much time in pool-rooms and watching trains come and go, you may make some money, but you certainly won't unless you work". He hit the nail on the head, and his interlocutor hit the trail, it is said.

The Sullivan outcrop, on the left side of the gulch, is now marked by caved workings. In the early days it was supposed to be the best part of the mine. Higher up the gulch are the Stemwinder tunnel and the ruins of another tramway-terminal. Looking back, it is remarkable how little confidence there was in this district even after ten years of productivity. Nobody looked more than five years ahead at the most. Now the miner says to his partners: "O hell! boys, we may as well quit, we can't dig it out". The average man in most mines expects to "dig it out" and anticipates looking for work elsewhere; he is essentially nomadic, and it takes no little self-repression to cause him to settle down like any other respectable citizen.

We climbed to the place of discovery, and, like Kellogg's donkey, surveyed the scene. The outcrop has been mined; in the caved open-cut the hanging wall has fallen, but the foot-wall remains exposed and well defined. That foot-wall has been the theme of much geologizing; it is known now as the Cate fault, after Oscar Cate, a miner. Looking around, it is evident that there was a glade or open space in the forest around the outcrop; here grew the bunch-grass that attracted the historic burro when he strayed up-hill from the gulch. The pinnacle of silvery galena was then, as now, the product of imagination; for Nature has her way of dulling the brilliant minerals of the underworld as soon as they are exposed, by erosion, at the surface. The line of the lode runs diagonally across Wardner mountain, across Milo gulch, and steeply up the other side across the ridge. As far as the eye reaches all is Bunker Hill property, for the company's mineral domain is 4 miles long by $1\frac{1}{2}$ miles wide. On the pitch of the ore-shoot underfoot the distance to the deepest workings is nearly a mile, and down there the showing of ore is better than the one that is supposed to have paralyzed the ass thirty-five years ago.

A hundred yards above the place of discovery, a good miner, Walker Johnson, is opening up a find that was overlooked despite the coming and going of thousands of men during the last thirty years or more. The lode here must resemble that of the original outcrop; not so wide, but similar in character. At the discovery the lode was 100 ft. wide and was stoped for 30 ft., although during the litigation some experts stretched it from the foot-wall over the mountain for half a mile or more. Johnson's find shows a reef or comb of quartzite, darkened by weathering and bearing patches of moss, in which, when broken, are exposed veinlets of bright galena, encased in oxidized mineral. It is a promising apex for a lead mine, for, as already stated, the showing made by lead veins or lodes at surface is rarely alluring. To find the masses of galena that yield profit to the miner, he must dig below

grass-roots and beneath the level to which oxidation extends.

Kellogg was named after the discoverer of the lode, as Wardner after its backer; the newer settlement is a great contrast both to Wardner as it is and as it was. As a town, Kellogg dates from July 7, 1893, when the original plat was filed with the auditor of Shoshone county. The 'History' says: "Kellogg has always enjoyed the reputation of a moral town, the first law by the authorities prohibiting a red-light district, and which has since never been permitted to be established. Rev. J. B. Orr, Congregational minister at Wallace, preaches at Kellogg on alternate Sundays." One may ask whether the law or the red-light district was "never established", but one can infer that the Reverend Orr's ministrations were highly effective. As I saw it, Kellogg looked a clean and cheerful town. It extends southward up Milo gulch and westward toward the mills of the Bunker Hill company, so that it is not a town of one straight avenue. The streets are well paved and well kept. In the centre of the town is a monument to Mullan. The inscription is as follows:

CAPT. JOHN MULLAN
TRAIL
1853-1855

Surveyor and Constructor of the military road from
Fort Benton, Mont., to Walla Walla, Wash.,
completed 1862.

Erected under the auspices of the Historical Society
of Montana Pioneers. Gift of Wm. A. Clark, Jr.
of Butte, Mont., to the city of Kellogg, 1918.

On the granite monument is the figure of Mullan in bas-relief. Standing here one can see the town-hall, a handsome structure of pressed brick, two bank-buildings, two hotels, and two cinemas. The day may come, but not for several decades, when Kellogg will be as Wardner, and eventually both "as one with Nineveh", but we ask the historian of a later day to note the difference between the places of amusement that Wardner boasted as against those of Kellogg. While there I went to one public entertainment, and that was an address on the Constitution by a distinguished local office-seeker, it being the day set aside for celebrating that great statement of fundamental principles.

From the centre of the town, one looks up Milo gulch to the wooded hillsides of the Wardner range and westward down the Coeur d'Alene valley to the settlement adjoining the Bunker Hill mills, with the chimney of the smelter appearing above an intervening hill. Northward are the river-flats and more pine-clad ranges.

The community dependent upon the life of the Bunker Hill mine is now so orderly and comfortable that it is difficult to realize what a picture of terrorism it presented 20 years ago. I refer to the strikes of 1892 and 1899, which gave to the Coeur d'Alene a sinister fame. It is necessary to refer to them, not only because of their effects on the Bunker Hill enterprise, but as illustrating the industrial conditions of a former period.

In 1890 a Consolidated Miners' Union was organized in

THE BUNKER HILL MILL AND FLUME IN 1892

Office Manager's house
THE SECOND MILL AS IT LOOKED IN 1893

the Coeur d'Alene and in 1891 a Mine Owners' Protective Association was formed. In July 1891 the Wardner union presented a demand to Victor M. Clement, manager for the Bunker Hill company, that the arrangement whereby the men paid a dollar per month for medical treatment without hospital facilities should cease, and that the same amount be deducted from each man's pay in behalf of the Central Miners' Union Hospital at Wallace. Early in August the manager replied by calling an election for choosing between three propositions: (1) to continue the existing arrangement; (2) to build a new hospital on the company's ground, the company to give the site and the lumber, on the condition that sufficient money was subscribed to pay all other expenses; (3) exemption from hospital taxation of the men signing a contract releasing the company from all liability for sickness or injury during their employ. Only a few men voted, and most of these favored the erection of a hospital at Wardner. The company gave notice of its intention to continue the dollar per month deduction for medical treatment and invited those who objected to 'get their time'. A strike followed. Sundry outrages were perpetrated. The strike ended, by compromise, in December. Other disagreements ensued at other mines in the Coeur d'Alene and as these synchronized with a dispute with the railroad companies over freight-rates, all the principal mines were closed down by January 15, 1892. In March it was announced by the Mine Owners' Association that satisfactory arrangements had been made with the railroads and that the mines would resume work, but only \$3 per day would be paid to car-men and shovelers, as against \$3.50 per shift of 10 hours to all miners.

In the statement published by the Mine Owners' Association, it was said:

"This scale of wages, after much consideration, has been determined upon as liberal and fair by the Association and it is hoped that it may meet the approval of all old employees as well as the public generally. The Association also announces that in all tunnel mines where a majority of the men desire to avoid working Sunday and Sunday night they may, on giving expression of such desire to the manager, have Sunday and Sunday night off each week.

"While we have no objections to miners' unions if they are governed and conducted by able, sensible, real miners, it is nevertheless a fact that during the years we have had unions in this country there has been trouble somewhere most of the time, strikes and threats of strikes, committees and delegations continually, to the great annoyance and loss not only to the miners but also to the community generally as well as to the mine-owners, and we challenge anybody to show in what manner the miners or owners or the community have been benefited one cent's worth for all the trouble caused, for all the time lost, for all the hard feelings engendered, for the many hard-earned dollars which the working miners have contributed to the coffers of the unions, excepting in the matter of the Sisters Hospital, which is a notable institution and worthy of generous support . . .

"The only men who can be said to have been benefited

at all are the car-men and shovelers, worthy men, no doubt, but it is well known that any reasonably intelligent man can learn to do this work in tunnel mines in a few days, and can it be said that these men are entitled to the same pay as skilled miners, who have spent years in learning their trade? We have endeavored many times to learn by what reason the unions demand the same pay for these men that they do for miners, but have failed entirely to get any good reason . . . Even admitting that the danger is equal to both miners and car-men alike, we would ask if the world's work is paid for without regard to skill? Does the locomotive fire-man get the same pay as the engineer? . . .

"It is true that the mine-owners raised the wages of car-men and shovelers last year at the demand of the unions, but they did so under protest and with a keen sense of its injustice. However, at that time lead and silver were much higher than at present, and desiring to get along amicably with the unions and being able to afford it, the wages of car-men and shovelers were raised. Now the conditions have changed; lead is only four cents and tending downward. Silver is below 90 and going lower, and the mine-owners are therefore under the necessity of the strictest economy."

I would like to quote *in extenso*, but space forbids. The pronunciamento proceeds to say that it is entirely a matter of business, that the ores are low-grade, and that strict economy is imperative. Moreover the capitalist followed the prospector into the region, and with the money and skill of the capitalist the mines were developed and equipped. Why then these threats to run them out of the country, to burn their mills, blow up their flumes, and even murder them? Does this talk of riot and murder do anybody any good? Who are the cause of it? A few agitators, not real miners, who terrorize the community, "their sole purpose being to keep up a continuous state of turmoil and strife to the end that tribute may in some way or another come to them".

Then the unions are warned by the mine-owners that any losses due to the destruction of mills or other property will have to be paid by the county. They seem to anticipate events. They expect that any concession will be followed by fresh demands. They say:

"We would ask if many of the leaders have not made up their minds that if they are successful in the present conflict, they will within 60 days urge a strike for \$4 a day for miners, for the closing of company boarding-houses, for a boycott on all business enterprises in which any mine-owner has an interest, for a rule that no miner will be allowed to work in any mine in the Coeur d'Alenes over seven days unless he joins the union, if not freely then by force, that no mine foreman shall discharge any man underground until he has given a satisfactory reason for so doing to the union."

Again it is evident that the mine-owners anticipate the union program with considerable accuracy. Their statement is long and discursive; it shows how warm the controversy has already become, for it mentions all those causes of trouble with which we are now familiar. It was not a fight between employer and employee, but be-

tween the owners of the mines and a group of agitators from the outside. The statement concludes by saying:

"We will simply add that we have determined that the wages cited are fair and liberal, and all we ought to be asked to pay, and having so determined we do not mean to start up our mines at any higher wages. We will wait until the first of April for our men to make up their minds, and if they decline to accept, we will have no other course but to claim the right to work our mines (which we paid for and own) outside of any unions, and we are fully determined to do so without any dictations from any association, conceding, however, the right to every person to demand any price they see fit for their labor as long as they do not interfere with the rights of others, and we feel confident the law will uphold us in so doing."

To this the Central Miners' Union of the Coeur d'Alene replied immediately, in terms that indicated the impending struggle. The spirit of the reply is suggested by the opening paragraph:

"As miners, we are not gifted with the literary abilities of the hired attorneys of the Mine Owners' Association, nor at the same time with the talent of making statements so absurd and false as to cause a blush of apology on the cheeks of Ananias, but as working-men we ask a thoughtful and considerate public to view both sides of the question before forming an opinion as to the merits or demerits of the case brought before their notice."

As a critic, I would say that the statements of the two parties do not differ greatly in literary style, and it is a safe guess that both of them were prepared by "hired attorneys". The Unions assert that "the late shut-down" was not due to wages but was intended "to crush out organized labor" and to introduce contract labor. They insist that the owners have made big earnings on their capital, except where the mines have been mismanaged. They complain of the condition of the lodging-houses and the quality of the board provided by the companies. They deny that the increased rate to the carmen was made under protest and that in certain mines the higher rate had been paid previously without the solicitation of the miners' union. They proceed to say:

"The Mine Owners' Association conveys the idea that we are nothing more nor less than a band of anarchists continually threatening the destruction of life and property, liable at any moment to carry out such threats if necessary to accomplish our purpose."

They ask where and by whom were such threats made? The history of succeeding events records the fact that the mine-owners were better prophets than managers and that the Union fulfilled the worst anticipations of its opponents.

The question uppermost in strikes is touched:

"There is no doubt that the mine-owners would not object to the unions provided they were officered by their nominees, but to this every member objects, as they should, in order to maintain some independence that in future as in the past they might be in a position to direct their efforts to mutually benefit all working-men and by

lawful means, and to state that the central or any other local union means in the future to select a county ticket to be voted on in the fall is a falsehood without a vestige of truth. . . . As for coercion in order to enlist members, the people here know well we have never used the like with one-half the force the Association has done to compel outside mines to fall in line. Will the Mine Owners' Association allow their constitution to be perused by the public? We think not, because from information now in our hands we know it is so opposed to law and

THE OLD REED MILL

order that the darkened archives of the Association is its safest retreat."

The proposal of the mine-owners was rejected; the mines were closed down and notice was given that new arrangements would be made to re-open them for work on June 1 (1892). Before that date the managers began to import miners from the outside under the guard of detectives. They also obtained injunctions from the Federal court, and served them on a number of persons, restraining them from interference with the operation of the mines. During June the mines were run short-handed and intermittently, chiefly by non-union labor. The 'History of North Idaho' says:

"The mines that came under the special displeasure of the union men were the Bunker Hill & Sullivan, at Wardner, and the Gem and Frisco, on Canyon creek. At the Canyon creek mines the feeling between the union strikers and the non-union men who had taken their

places and were working under guard was very bitter. Exchanges of harsh words were frequent and fist-fights were not uncommon. These eventually precipitated an armed encounter on July 11th between union men and the employees and guards of the Frisco mine. At about five o'clock in the morning of that day the firing commenced. It is said by both sides that the shooting was not intended at first to do other execution than to frighten the men out of the mine. Soon, however, a pitched battle resulted, both miners and guards firing to kill. The strikers were at a disadvantage, so withdrew up the hills. It was now that the plan of destroying the mills took shape in their minds. They came to the end of the tramway, placed some giant powder in a car and started it to the buildings on its errand of destruction. The fuse was too short, so the explosion took place too soon to do serious damage, though the tramway was destroyed. Powder was then carried to the flume and, the water having been turned off, sent down the penstock and to the water-wheel. The old mill was thus wrecked, for fortunately most of the men had withdrawn to the new mill, thus saving their lives. The men in the mill continued firing a short time, but soon realizing their hopeless position, surrendered.

"Soon the battle began at the Gem. The men in that mine had made some preparation by erecting barricades of wood and lumber. As the night shift was going off and the day force going on, the firing began. After a large number of shots had been exchanged by the strikers in the town of Gem and the men at the mine, a conference was held under a flag of truce, in which it was agreed that the non-union men should surrender if so advised by A. L. Gross, the only member of the Gem company in the country. Gross advised the surrender and the men handed over their arms.

"In the two battles two non-union men were killed, namely John Starlick and Ivery Bean, also three strikers, James Henessy, Gus Carlson, and Harry Cummings. A considerable number were wounded.

"After their victories at the Gem and the Frisco the strikers proceeded to Wardner, going from a point outside of Wallace to the junction in two freight-cars propelled by gravity. They arrived after dark on the night of the 11th, took possession of the Bunker Hill concentrator and placed a ton of powder under it. Next morning Mr. Clement had the choice of discharging his non-union employees and sending them out of the country or having his mill blown to pieces. Under the circumstances he agreed to send the men away, which was done.

"Many of the non-union men left the country July 12th, going by rail to the Mission and arriving at that point about three o'clock. The steamer was transferring troops across the lake and did not reach the Mission until one o'clock next morning. While waiting, the non-union men were made the victims of an outrage which has been condemned by both parties to the quarrel as a dastardly and utterly inexcusable affair. Persons whose identity is unknown to the writer and perhaps not known with certainty by many outside of their own number, came down on a hand-car to the Mission and attacked the unarmed

men with guns. The men fled, of course. They were pursued by the attacking party over the meadow toward Fourth of July canyon, six miles distant, and all of them subjected to the hardship of spending a night in various hiding-places. Those who took refuge along the banks of the river either made their way back to the Mission in small boats or were picked up by the steamer next morning. From the number missing it was supposed that many had been killed, but no bodies were found, although diligent search was made for them. At least one man, John H. Abbott, was severely wounded in the left breast by a bullet, so that he was not expected to recover, but we are informed that he eventually did. The purpose of the attack was doubtless robbery rather than bloodshed. Many of the victims had everything in the world that they possessed taken from them. It should be added that the miners' union of the Coeur d'Alene emphatically denied that it or any of its members had anything to do with this outrage, directly or indirectly.

"Martial law was promptly declared, and under the protection of the soldiers many of the expelled non-union men returned. With such help, the Bunker Hill & Sullivan resumed work before July 1. Many of those who were most active in the uprising were compelled to flee from the country; many others were placed under arrest, but only a comparatively few were convicted and punished. Twenty-five were tried in the Federal court on a charge of violating the restraining order, and of these Thomas O'Brien was sentenced to eight months and F. T. Dean, R. M. Boyce, Thomas Henney, and Thomas Doyle to six months imprisonment. A number were tried at Coeur d'Alene City for conspiracy and four were sentenced to the House of Correction at Detroit, Michigan; George A. Pettibone for two years, M. L. Devine and Charles St. Clair for 18 months, and John Murphy for 15 months. Gradually the troops were removed, and on November 18, 1892, martial law was revoked."

It is a miserable story. Even the shooting was poor! Think of all the gun-play that took place at the Gem and Frisco mines, yet only five men were killed. A side-light on these events is afforded by Charles A. Siringo, a detective engaged by the Mine Owners' Association. In his book, 'A Cowboy Detective', published in 1912, he relates his experiences during this strike. Acting under instructions, he played the part of a miner and joined the union at Gem. His reports were mailed to St. Paul, Minnesota, where a copy was made and sent to the secretary of the Mine Owners' Association at Wallace. Siringo, or 'Allison', as he then called himself, was elected secretary of the union; whereupon he did the correct thing, shirked work, and was discharged. In order to remain secretary, he pretended that his father sent him money from Texas. The treasurer of his union was George A. Pettibone, a justice of the peace, mentioned among those who were punished for their crimes. With Pettibone and other union men he would order 'scabs', that is, those refusing to join the union, out of the country and, if necessary, "get up a mob, by holding a citizens mass-meeting, to run them out of the State". Only

members of the union were permitted to enter the "citizens' meeting". He describes the sequel:

"Then it would be declared the sense of the citizens' indignation meeting that certain 'scabs' be run out of the State. Often as many as half a dozen 'scabs' would be taken from their homes, sometimes with weeping wives and children begging for mercy, and with tin pans and the music of bells, they would be marched up and down the street to be spit upon and branded as 'scabs' before the public eye. Then half-clothed and without food, the poor devils would be marched up the canyon, a few miles beyond Burke, and told to hit the road. Pistols would be fired over their heads to give them a good running start. By this route, during winter, the snow is waist deep over the Bitter Root range, and there is not a living inhabitant until reaching Thompson's Falls, Montana, a distance of about 30 miles. This thing was kept up all winter, and I learned a few new lessons in human nature." His reference is to the winter of 1891-'92.

When war was declared between the mine-owners and the unions in the spring of 1893, the sheriff of the county was friendly to the unions, as Allison informed his employers, so that a trainload of strike-breakers passed through Wallace without stopping, thereby eluding the sheriff, who stood ready to arrest them under the State law against importing armed thugs. Each side invoked the law and both sides broke it. It was a lawless fight, a reversion to frontier lawlessness. Other trainloads of strike-breakers were imported under armed guards. It became evident that the secrets of the Gem union were being given away by a traitor, so a Butte detective was put to work to spot him, and Mr. Allison's job became uncomfortable. He was charged with disloyalty at a meeting called for the purpose, but managed to bluff his accusers. Two days later he had reason to believe that he had been recognized by a man whom he had helped to convict in Nevada. It was time to skip. He hid under the sidewalk, and while there saw some of the fighting and heard the explosion at the Frisco mill. Crawling under the sidewalk, he escaped, while angry men on top were discussing what they would do to him. He makes a good story of it. A few days later he was kept busy identifying the union leaders, who were arrested by the troops under General Carlin and placed in the 'bull-pen', a large stockade with a frame building in which the prisoners slept and ate. In less than a week 300 were in the 'bull-pen', which was at Wardner. Our author, the detective, concludes his description of his experience thus:

"The Coeur d'Alene trouble had been caused through the miners' union wanting to dictate as to how the mines should be run. When they made a demand for shorter hours, and that 'muckers' and common roustabouts receive \$3.50 per day, the same wages as skilled miners, the mine-owners closed down the mines and sent out for non-union men."

Work at the mines was resumed, the bad men were arrested or driven out of the district, and order was restored, but the feeling of bitter antagonism survived between union and non-union labor. Several outrages were

committed, one of the worst being the murder of John Kneebone in July 1894 and the expulsion by force out of the county of R. K. Neill and three other men. On April 23, 1899, a demand was made on the Bunker Hill company by the Wardner union for a uniform wage of \$3.50 to all underground men and for the recognition of the union, now organized with the Western Federation of Miners. The manager, Frederick Burbidge, said he would submit the matter to the other officers of the company; they agreed to increase wages of all laborers from \$2.50 to \$3 and of all miners from \$3 to \$3.50 per day, but refused to recognize the union. On April 26 the tramway was seized by a group of armed strikers and men were stopped from going to work.

On April 29 a group of masked men at Gem took pos-

'OLD GLORY' ASSERTING THE RESTORATION OF LAW AND ORDER; JULY 1, 1899

session of a train from Burke, they compelled the engineer to back the train to the powder-house at the Frisco mine, where 70 boxes of dynamite were loaded on a boxcar. The train then went to Wallace. There a number of men from Mullan got on board. Proceeding to within a mile of Wardner, the engineer was compelled to stop the train while another group of men boarded it. By this time the mob on the train numbered about a thousand, of whom 300 were masked and armed. They left the train and went to the Bunker Hill mill, which was then completely destroyed by the use of several hundred pounds of dynamite.

As soon as the echoes of the explosion had died away among the surrounding mountains, an ominous silence

ensued, to be broken by a deafening fusillade from the train, this being meant to celebrate the 'victory' of the ruffians posing as labor reformers.

Nobody was killed at the mill, but during the excitement that followed John Smythe, a Frisco miner, was shot and killed; James Cheyne, a vanner-tender of the mill, was fatally wounded; and R. R. Rogers, stenographer with the Bunker Hill company, was wounded. Smythe is said to have been killed by the strikers because he was suspected of being a 'traitor'; for the killing of Cheyne a man named Corcoran was convicted and sentenced to 17 years imprisonment.

Those were bad days for the staff at the Bunker Hill. Wisely, they did not meet violence with more violence, for that would have settled nothing. Friends came from Gem to warn them of the impending danger; they were told that 500 men had stolen a train, opened the Frisco powder-house, broken into militia headquarters and seized rifles, and were coming down to blow up the mill. Word was passed for everybody to abandon the property and seek safety. Mr. Clark tells me that after he had seen "the mill go up" he noted the sun glistening on the dinner-buckets of a group of men on the hillside coming down from the mine toward Government gulch, so as to avoid Wardner. Mr. Burch was with them. The whole party walked to the mouth of Pine creek, where they camped. J. C. Bodley, an old-timer, made 'biscuits' for them that night. They waited until 11 p.m., when a special train sent by the president of the company, Mr. Bradley, came up from Tekoa. At Cataldo they picked up Mr. Burbidge, who had escaped over the river flats. On arrival at Tekoa, at 5 a.m. next day, they breakfasted, and four hours later took the train back to Kellogg, where they found that the strikers had gone and everything was quiet. The Kellogg adit was being driven at that time and the management was anxious not to suspend this particular work, so, as the power-plant had been destroyed, the old plant in Milo gulch was brought into use and an Edison bi-polar dynamo was installed for driving the cars in the adit. Lights from the same dynamo were used to illuminate the bull-pen at Kellogg, where 500 men were imprisoned all summer. This is the second mention of a 'bull-pen'. Again United States troops were sent into the district, on appeal from the Governor of the State. General H. C. Merriam was in command. He 'rounded up' those suspected of complicity in the destruction of the mill and placed them in the bull-pen. Most of those charged with major offenses escaped and those charged with minor offenses were released, because the County declared itself unable to try so many persons. Owing to complaints made against the harshness with which the prisoners were treated, the matter was referred by Congress, on January 8, 1900, to an investigation by the Committee on Military Affairs. It was charged that there was issued and enforced by General Merriam a proclamation in violation of the Constitution of the United States and of the State of Idaho. It reads as follows:

"Whereas the following notice has been served upon

the mine-owners of Shoshone county by the duly constituted State authorities, by whom martial law has been declared, to-wit:

"To the mine-owners of Shoshone county:

"Certain organizations or combinations existing in Shoshone county have shown themselves to be criminal in purpose, inciting and, as organizations, procuring property to be destroyed and murders to be committed, by reason whereof it has been twice necessary to declare martial law in Shoshone county.

"You are therefore notified that the employment of men belonging to said or other criminal organizations during the continuance of martial law must cease. In case this direction is not observed your mines will be closed."

The effect of this proclamation, of course, was to prevent union men from obtaining work in the county, whereupon the authorities, civil and military, were charged with "an outrageous misuse of the military power of the United States . . . in the interest of the owners of the Bunker Hill and Sullivan mines." After an investigation that lasted three months, the committee reported that none of the 'whereases' were sustained by the evidence, but a minority of seven condemned the action of the President, the Governor, and the General.

The trouble-makers were scattered effectively and normal conditions of production were restored by the end of the year.

Another incident needs to be recorded. The Western Federation of Miners, an organization at that time dominated by criminals masquerading as labor-leaders, bore a grudge against Mr. Bradley, as the president of the Bunker Hill company. So they told one of their number to assassinate him. The story is told in the 'Confessions of Harry Orchard', published in 1907. Horsley, *alias* Hogan, *alias* Orchard, assassinated Frank Steunenberg, former Governor of Idaho, on December 31, 1905. While in prison at Boise, during 1906, he wrote the 'Confessions'. One chapter is entitled 'How I went to San Francisco and Blew up Fred Bradley'. It appears that in August 1904, W. D. Haywood, secretary-treasurer of the Western Federation of Miners, and George A. Pettibone, who was sentenced for two years on account of his doings in the first Coeur d'Alene strike, arranged with Orchard, at a meeting in Denver, "to put Fred Bradley out of the way". Orchard proceeded to San Francisco and prepared for the crime. Pettibone sent him \$100 each month. He had brought 10 pounds of dynamite for making a bomb and engaged a room a few doors from Mr. Bradley's home on the corner of Leavenworth and Washington streets. Mr. Bradley was in Alaska when he arrived, so Orchard waited until his return to San Francisco in October. He watched for him "with a shotgun loaded with buck-shot, and tried to catch him coming home at night; but it was not light enough to tell him from the rest" of the people living in the flats in which Mr. Bradley resided. So he put strychnine in the bottles left by the milkman in the early morning. He says: "I figured the girls [the servants] would serve Mr. and

Mrs. Bradley's breakfast first and they would get the poison first". He had made the acquaintance of the servants while spying about the place. It happened fortunately that the cook had occasion to taste the milk, found it bitter, and informed Mrs. Bradley, who sent out for a fresh supply. So this diabolical plot miscarried. Next he prepared his bomb. "I bought a piece of five-inch lead pipe about a foot long at a plumber's," he says, "and put wooden ends in it. Then I hammered one side of it flat, so it would lie straight without turning over, and I cut a piece out of the other side, and turned back the flap and fastened a little vial on this, so that when you filled it with sulphuric acid, and you pulled out the cork, the acid would run out into the hole in the pipe. Then I filled up the lead pipe with about five or six pounds of No. 1 gelatin, and put some caps and sugar and potash on top of this and opposite the hole in the lead pipe, so the acid would fall on them. Then I planned to hitch a little string to the cork of the bottle, and fasten the other end of the string in a screw-eye in a door, so when you opened the door it would pull out the cork and set off the bomb."

He practised with it in his room, omitting the cap and acid, until he felt sure it would work. He noted Mr. Bradley's habits and decided to "get him" as he came down after breakfast on his way to his office. In order to make certain, he telephoned to Mr. Bradley, posing as a miner from Goldfield, Nevada, and made an appointment with him at nine o'clock in the morning at his office. On November 17, 1904, he placed the bomb on the stairway, so that the opening of the door would cause it to explode. He left his room and wandered about the town, waiting to read in the evening paper how well he had succeeded in his foul deed. In due course he read an account of the explosion and that if Mr. Bradley did not die, he would lose both hearing and sight. The explosion was imputed to the leaking of gas and the Pacific Gas & Electric Co. actually had to pay \$10,000 damages to the owner of the flats, after a lawsuit that went as far as the Supreme Court.

The stairway and entrance were blown to pieces and Mr. Bradley was hurled into the street, badly injured, of course, but, most fortunately, the first fear of a loss of sight and of hearing proved wrong, and he was himself again within a few months. On arrival at Denver, says Orchard, "Pettibone was well pleased with the news, but said it was hard luck that it did not kill him". Orchard is still in jail, for, on account of giving evidence against his associates, he was not hanged. Haywood has continued in his career and is now again in jail, as a leader of the I. W. W. One of the features of the murders and assassinations perpetrated in the name of a false kind of labor unionism is the repeated re-appearance of the same criminals as the agents of disorder and crime in various mining districts and the apparent failure of the law to discipline them. Even public opinion has failed to stimulate the officers of the law to the proper protection of the community.

(To be Continued)

Determination of Molybdenum

The Bureau of Mines has recently issued Technical Paper 230, 'Determination of Molybdenum', by J. P. Bonardi and E. P. Barrett. This report presents the results of an investigation by the Bureau on methods of analysis for determining this metal. During the recent activity in the molybdenum market the old and well-known methods for the determination of molybdenum in ores were found inadequate. They were satisfactory for high-grade material, but, on account of the advent of flotation methods and the inflation of the market because of the War, the grade of products became so low that the molybdenum content needed to be determined to the second decimal place.

The Bureau, therefore, began an investigation to devise a more accurate method for determining molybdenum in low-grade ores. The results of the first efforts disclosed the fact that the required degree of accuracy was difficult to obtain by the various methods in use. The method used must be rapid as well as accurate, as a company treating a low-grade ore must know the results not later than the day after the samples are taken in order to control closely the mining of the ore as well as the operations of the milling plant.

Some of the quantitative methods for the determination of molybdenum that are in general use are as follows: (1) Precipitation as the sulphide from acid or alkaline solutions with or without increased pressure; (2) precipitation as mercurous molybdate; (3) precipitation as lead molybdate; (4) titration with lead acetate; (5) titration with potassium permanganate; (6) titration with titanium chloride; (7) the iodometric method; and (8) titration with potassium iodate.

Of these methods, that of reduction of the molybdenum and titration with potassium permanganate proved the most suitable for rapid accurate determinations on low-grade ores. The ore is decomposed either by acid or by fusion with sodium peroxide into a soluble molybdate and insoluble compounds of the other constituents of the ore. The molybdate is filtered, acid added, and the solution is passed through a Jones reductor where the MoO_3 is reduced to Mo_2O_3 . The solution is then titrated with potassium permanganate and the percentage of molybdenum present is calculated. Successful use of the method, however, requires close attention to details of procedure as outlined in the report. Gravimetric determination of molybdenum by precipitating and weighing as lead molybdate is rapid and accurate, but certain precautions must be observed. In this method the ore is decomposed with acids and treated with ammonium hydroxide to form ammonium molybdate. From the hot solution the molybdenum is precipitated as lead molybdate by adding lead acetate solution, 2 or 3 cc. in excess, heating the mixture a few minutes, and filtering. The precipitated lead molybdate is then ignited, cooled, weighed, and the weight of molybdenum is calculated. A copy of the pamphlet detailing the procedure may be obtained from the Bureau at Washington.

Metal Mining in California

The conditions in the metal-mining industries in California during the first half of 1920 were even more burdensome to the operators than in 1919. The high cost of supplies and labor and the scarcity of skilled labor have increased the number of mines that have suspended or curtailed operations and have materially lessened the output of metals, according to C. G. Yale, of the U. S. Geological Survey.

During the first six months of 1920 the U. S. Mint and local smelters and refiners, to which most of the newly mined gold from California is sent, received from the mines of the State \$7,811,390 in gold, or \$1,086,739 less than during the first six months of 1919.

In 1918 there was a decrease in the production of gold in California, compared with 1917, of more than \$3,500,000, but in 1919, with an estimated production of \$17,380,000, there was an increase of \$852,000 over 1918, which showed some progress toward the recovery of a normal output. However, if the monthly receipts at the mints, smelters, and refineries for the last six months of 1920 continue at the same rate as in the first six months, the total output of gold in California in 1920 should be \$15,622,000, or \$1,757,000 less than in 1919.

The silver received during the first half of 1920 by the mints, smelters, and refineries amounted to 503,794 oz., 376,310 oz. more than in the first half of 1919. This abnormal increase in the output of silver is due entirely to operations at a new silver mine discovered in 1919 in San Bernardino county, just over the border of Kern county. Most of the silver heretofore mined in California has been obtained as a by-product in the mining of gold, copper, and lead ores, for few purely silver mines have been operated in the State. During the last year, however, a number of old silver mines, most of them in Inyo and San Bernardino counties, have been re-opened, owing to the high price of the metal.

The loss in the output of gold is caused by curtailment in the operations in certain large mines on the Mother Lode and elsewhere and by stoppage of work on a large number of mines. Many properties that were worked profitably under normal conditions continue to be operated at a loss. Once shut-down and filled with water, such mines may never be re-opened. Two of the most productive mines of the Mother Lode, with workings extending vertically below 4000 ft., had to be flooded to extinguish disastrous fires, and now hard and expensive work is being done to unwater them. On the Mother Lode five or six years ago a profit could be made on ore that yielded \$3.50 per ton, but now nothing can safely be classed as ore which contains less than \$6 per ton. Not only the quartz but the placer field is affected. Six years ago one large dredging company, handling about 36,000,000 tons of gravel yearly, worked 14 dredges, which dug up \$2,637,700 in gold at a cost of \$15 per ounce. In 1919 it worked 11 dredges, and the gold output of \$1,840,000 cost \$23 per ounce. It is found less expensive, however, to sustain the loss than to close down the plant, for the loss through taxes, insurance, deterioration of

equipment, and breaking up of organization would be greater.

At Grass Valley, the most productive quartz-mining district in the State, the larger mines are severely affected by a shortage of skilled miners, for higher wages in lumber-camps and shipyards have induced many men to give up mining. The Empire mine, the most productive deep gold mine in the State, has made extensive improvements in 1920. The North Star mine continues production but at a less rate than during normal times. At Jackson and Sutter Creek, Amador county, the most productive district in the Mother Lode, the principal producers have made little output this year, owing to the necessity of unwatering the mines after flooding them to extinguish fire. The highly productive activities of the recently re-opened Morgan mine, Calaveras county, are noteworthy.

Shortage of water throughout the hydraulic-mining regions in Sierra, Plumas, Siskiyou, Trinity, and other counties, where this class of work is carried on, has greatly reduced the production of placer gold. Drift-mining has also languished, and no new properties of note have been opened. The dredge-mining industry has probably suffered less than other gold-producing operations, yet skilled labor has been scarce and costs have been greater, and reduced prices have materially lessened output and profits.

Copper mining in California has not been in good condition this year. What was formerly the largest producer, the Mammoth, in Shasta county, continues closed down and other large mines are idle. The Mountain Copper Co., at Keswick, started work again this year in its Iron Mountain and Hornet mines and is reducing its ore at the smelters on San Francisco bay. Operations have been curtailed at the mines of both the Calaveras Copper and the Penn Mining companies, in Calaveras county. Plumas is now the most productive copper-mining county in the State. The principal mines, the Engels and the Walker, continue operations and have made many permanent improvements at their plants. The Cerro Gordo mine, near Keeler, the largest producer of lead-zinc ores, has again been started, and ore is being shipped by the Rip Van Winkle, Lucky Jim, Utacala, Sterling, and other mines around Darwin. Most of the zinc mined in California in 1920 will come from these southern counties, as very little has been produced in Shasta county.

THE highest grade pumice at present mined is of Italian origin. The seat of the industry is the volcanic island of Lipari, one of the group lying off the north coast of Sicily about 40 miles from the Italian mainland. The methods employed in mining are primitive. The deposits for the most part are found near the surface, and the material is extracted by drifts driven only a few yards into the hillsides. The output could be increased if these drifts were properly timbered so as to follow up the profitable strata. Without support the danger of caving necessitates the abandonment of the drifts before they are worked out.

Conditions in Mexico

By An Occasional Correspondent

The Mexico City version of the early history of General Pablo Gonzales, reported in my July letter, I have recently found to be incorrect. Don Pablo did not reside in the United States as a youth nor did he marry an American wife; his knowledge of English was acquired by residence on the Mexican side of the Texas border, and when Carranza revolted against Huerta in 1913, the future presidential candidate was merely a book-keeper in the flour-mill of his German father-in-law at Monclova, the State capital where Carranza was governor. All of which is a preliminary for giving a final farewell to Don Pablo as a public character of note.

Even though Don Pablo's desertion of Carranza was

ranzista governor of Mexico City; Ricardo Gonzales; and Ironeo Villareal.

However, the campaign of these rebels against the new government were of short duration, as they foolishly started operations in the deserts on the Rio Grande border, where, lacking control of the railways, they were unable even to feed their troops, much less keep up a supply of munitions. Osuna was soon defeated and fled with a few followers into the mountains. Blanco and Mireles, after a few reverses, escaped into Texas. Meanwhile Gonzales and Villareal were fighting between Laredo and Monterrey, and happened to attack the latter city while Pablo Gonzales was visiting there. On this suspicious coincidence, the Government ordered the immediate arrest of Don Pablo and his gang, but while the generals José E. Santos, lately governor of Nuevo Leon, and Carlos Garcia, chief of staff, were soon found and jailed, the king-pin himself was only discovered after a long search and was then found concealed in the chimney of his cellar. About this time, General Guajardo was also captured in Monterrey, having entered the city in disguise in order to obtain recruits and supplies. The unlucky Guajardo was at once tried and shot, on July 19, as a spy; and many, remembering the usual fate of Carranza's opponents under like circumstances, expected a tragic sequel also to the court-martial handling the case of Don Pablo. Nevertheless the court, being given a free hand by the Government, found no evidence implicating the latter in the sedition of his subordinate generals and were therefore obliged to release him. This unexpected denouement produced an excellent impression everywhere and probably had much to do with the surprising fact, reported by the Minister of War on August 1, that not a shot had been fired by the Federal army against rebels anywhere during the previous week.

ON THE TRAIL

the main cause of Obregon's quick and easy victory over the Government, the entrance of the victorious rivals into Mexico City in May as friends seemed to offer little hope of permanent peace between them. Everyone was therefore relieved, as well as surprised, when Don Pablo soon announced in the papers the withdrawal of his presidential candidacy for patriotic reasons. The real reason, however, was fear of Obregon, who had packed Mexico City with 30,000 devoted troops, drawn from his Sonorans and the Zapatista hordes, and had then proceeded to notify Don Pablo that it was now a case of 'fight or get out of the ring'. While Don Pablo—luckily for the public—proved a coward, some of his friends were more pugnacious, so that the rebellion of various lesser generals soon ensued. Among the latter were Jesus M. Guajardo, who earned his high rank last year by slaying the famous Zapata; Carlos Osuna, once a Protestant preacher and lately governor of Tamaulipas; Espinasa Mireles, the governor of Coahuila; Lucio Blanco, who in 1914 was recreant to his trust as Car-

While it requires skilled diplomacy to get a Mexican rebel to surrender, it often requires even more to keep him peaceful. For instance, the Zapatista general, Genevevo de la O, who in May had accompanied Obregon on his triumphant entry into Mexico City, became surly on his forced retirement to Cuernavaca in June, and was only restored to good humor by being allowed to name the governor of Morelos. As the generals Gildardo Magaña, successor of Zapata as chief of the Liberating Army of the South, Valentin Reyes, and Everardo Gonzales had joined Obregon at the same time as Genevevo, the surrender in July of the generals Saveedra and Mendoza signified the practical finish of Zapatism as a rebellious political movement.

In Puebla, the notorious brigand Higineo Aguilar, who has been in arms against all the various Federal regimes since 1909, has tendered his submission; and this means

the possibility of again resuming mining in the South, distracted since 1914. A strong argument for the fatalist view of life might be found in the case of General Meixueiro of Oaxaca, who, active in arms against Carranza for five years past, died last month quietly in his bed within a few weeks of his reconciliation with the Government. In July the rebel bands of Chiapas and Tabasco also submitted, and the generals, Manuel Larraza and Leon Martinez, who had plagued the State of San Louis Potosi. Even distant Sonora has its tale of pacification, for some of the Yaqui tribes, in revolt since the Diaz epoch, after a severe defeat administered to them in April at Bacatete by the army of General Elias Calles decided to lay down their arms.

What seems almost too good to be true is the expected speedy rendition of Pancho Villa in accordance with a contract just drawn up between him and a Federal envoy. In return for his submission, Villa is to be given the ranch of El Canutillo in Durango and provided with an operating force of fifty of his friends, whose wages will be paid by the War Ministry. Those of his troops who desire to do so, will be incorporated into the Federal army, the remainder will be mustered out with a year's salary as a present, and each man given sufficient land to start a farm of his own. The cessation of Villa's brigandage will be an inestimable boon to American mining enterprise; indeed, as first fruits of the expected surrender, the Mexican Bureau of Mines reports that 400 companies have filed applications for resuming work in Villa's old stamping-ground in the central North.

The only remaining war-cloud is one newly arisen in the Territory of Lower California, where the Carranzista Governor, Esteban Cantu, has reigned for many years as an almost independent satrap. At first Cantu tendered his allegiance to the new government; but, when summoned, a little later, to Mexico City for a conference with President De la Huerta, the satrap refused to budge and began to fortify his territory to resist invasion. About this time, various Carranzistas—proscribed by the new government as vulgar criminals, or else irreconcilable—who had escaped to the United States, held a meeting at San Antonio, Texas, under the leadership of the infamous Luis Cabrera. They evidently voted to back up the rebellion of Cantu, because Lucio Blanco soon left for Lower California to lead the rebel army, and a number of these exiles are now aiding Cantu with money and advice.

The new provisional president, Adolfo De la Huerta, should not be confused with the unspeakable Victoriano Huerta, who sprang from quite a different family and State. Besides being twice governor of Sonora—once in 1916, by appointment, and again in 1919, by election—Don Adolfo was sub-secretary of Gobernacion in 1915 and Federal senator in 1918. Partly of Indian blood, he was this year elected chief of the Yaqui nation. In his youth he enjoyed an education unusually good for a Mexican; in consequence he is open-minded toward new ideas and progressive in his political tendencies. Personally, he is affable and democratic, and his popularity is evidenced by the testimony of Villa, who gives his ad-

miration of De la Huerta—with whom he was associated in 1913—as one of the leading motives for his proposed surrender. Of early-middle age and naturally robust, he is at present suffering from appendicitis, which interferes lamentably with his desire to fulfil properly the numerous duties of his high office.

The new government has extended amnesty toward all Carranza's followers, except those guilty of vulgar crimes. Among the latter, Luis Cabrera was cunning enough to evade capture and escape into Texas, whither Juanito Barragan soon followed him after he had eluded his jailers in Mexico City by an unscrupulous trick. Thence fled, too, Colonel Fontes, the despoiler of the National railways, and General Candido Aguilar, son-in-law of Carranza and erstwhile liberator—and looter—of fertile Vera Cruz. Of all the old ring, only two notables were safely jailed, Licenciado Berlanga, minister of Gobernacion, and General Murguia. The former is now on trial on charges of misappropriating public funds and corrupting the daily press; but the latter turned honest some years ago, so that evidence to incriminate him now is probably lacking. Yet while engaged in accumulating his present considerable fortune, Murguia was perhaps as audacious as any of his 'reforming' confrères. Not content with the usual conventional toll of a Carranzista general arising from a shamelessly padded payroll and supply-list, Murguia seized for himself in 1915 the whole of two bonuses—one of \$300,000 and the other of \$150,000—sent to him by Carranza to be distributed among his troops as rewards for their successful campaign in the West.

As the first fruits of Don Adolfo's campaign against military graft, his government now finds itself with sufficient funds to pay its civil servants henceforth fully in cash, instead of the payment of 75% cash and 25% bonds practised by Carranza. Not only graft must go, but all superfluous troops, and especially the scandalous redundancy of officers maintained on public pay since 1915. A garrison with one general and eight or ten lower commissioned officers to 100 private soldiers and 'non-coms' was a common thing; while in certain centres, like Mexico City, were assembled the 'unattached' officers, in huge droves, which resembled nothing so much, in their lack of social utility, as the bachelor-seal herds or the similar *guanaco* bands of the Andes. A recent comical incident of army revision was the case of a general who thankfully accepted the rank of lieutenant rather than suffer the calamity of complete erasure from the army payroll. The proposed speedy reduction of the army to 50,000 men is certainly the first move essential to any economic rehabilitation of the country. Last year 120 out of the 200 million pesos of Federal revenue was spent by the War Department.

The Department of Bienes Intervenidos (intervened properties) was originally instituted by Carranza as a scheme to deprive his political enemies of any funds with which to oppose him. It has its excuse in the shameful betrayal of Madero by the Diaz *científicos* after he had been so foolishly generous as to leave undisturbed their huge fortunes stolen from the nation. The intervened

properties comprised not only hundreds of the ranches, mines, factories, and residences of individuals, but numerous schools and asylums belonging to the Catholic

high-grade ore. Originally proclaimed as a temporary measure, the intervention department proved so profitable to its operators that it was continued in full blast

GENERAL ALVARO OBREGON

church. Many of the large buildings intervened were used as military barracks, and, as most Mexican soldiers have the personal habits of swine, the effect of their resi-

until the fall of Carranza. The new government has now reversed this policy and is returning the intervened properties as fast as their owners can be identified, while the

THE LATE PRESIDENT CARRANZA AND SENOR PABLO GONZALES

dence on the furniture, woodwork, and decorations of these edifices can readily be imagined. The intervened ranches were usually stripped of their livestock and other chattels, while the mines were gutted of all developed

Department itself will be abolished in September.

Outside the National system of railways, of which control was obtained through stock-ownership by the Federation in the time of Diaz, the leading trunk-line of the

country is the 'Mexicano', which was first intervened by Carranza in 1914 and continued (except for an interval in 1916-'17) in his possession until his fall. This line has now been returned to its English owners, who will be indemnified later for their long deprivation of its earnings.

Next to the President, the leading public figure at present is General Salvador Alvarado, the Minister of Finance. A revolutionist ever since 1906, when he helped to lead the great strike in Cananea, Alvarado first rose to fame in 1915 when he invaded Yucatan as a Carranzista general and soon became its military governor. His administration of the State, which lasted till 1918, was one of the most extraordinary phenomena of the Revolution. Yucatan, a country of half-savage Indian peons and vast henequen plantations, was transformed (on paper) by Alvarado into one of the most civilized Utopias ever conceived, in fact or fiction. In 1918, evidently tired of playing the game of a creative statesmanship that failed to function, he left Yucatan. During 1919 he amused himself, and dropped \$100,000 of his savings in starting a new Mexico City daily, 'El Herald Mexicano'. Later he was arrested by Carranza and tried for sedition, but for lack of evidence was acquitted. Shortly after he took refuge in the United States and published his famous exposure of the Carranza administration.

Having always been an ardent supporter of his fellow Sonoran, Obregon, on the triumph of the latter he naturally was given a high place in the new government. In his present office, Alvarado has been as active and audacious as ever, chiefly busying himself with uncovering the corruption of his predecessor, Luis Cabrera. The first mare's nest exposed was in the Casa Monetaria (Treasury bank) which had made loans of two million pesos to various Carranzistas without any security. Next came two bureaus of the War Ministry, the first of Military Police and the second of Military Instruction in Public Schools, which employed numerous officials and cost two millions per annum, but never did any work. Later, he abolished the use of the 'infalsifiable' paper money, which, ever since its demonetization in 1916, has been 'redeemed' by requiring a bonus of its bills to be added to every payment of certain Federal taxes assessed in coin. He now proposes to launch the Banco Unico (unique bank) which has been mooted ever since 1916. This bank will monopolize the issue of bank-bills formerly distributed among the State banks—looted in 1916-'17 by Carranza—and if its inauguration is accompanied by doing justice to the latter it will mean much for the restoration of normal commercial facilities, lacking since 1914.

The recent re-opening of the kidnapping case of U. S. Consul Jenkins of Puebla has exposed to the public gaze the clumsy conspiracy hatched by Carranza to incriminate Jenkins in order to relieve his government of any responsibility for re-payment of the \$150,000 ransom. Exactly why Carranza should have gone to all this trouble is inexplicable, for he could easily have filed the Jenkins claim, along with the thousands of others, in the

archives of his fundless Claims Commission, and let it go at that.

Last month the Republican (Catholic) party held a convention in Mexico City and nominated an engineer, Robles Dominguez, for the Presidency. This is the first time the Catholics have dared to hold a political meeting since 1914, and though Dominguez has perhaps no chance of being elected, the very fact that his candidacy is permitted by the Government shows how things have changed.

A recent Federal decree, designed to encourage the resumption of mining, remits the usual fines for non-payment of back taxes for all delinquents who will pay up for the first and second thirds of this year before August 31. Previous back taxes may be paid pro-rata with future current payments until liquidated, but failure to now take advantage of this final and liberal offer will result in forfeiture of the mining claims or titles involved.

The same syndicalist propaganda that was widely subsidized by Carranza in 1915, as a weapon against his rivals, but suppressed by him in 1916 on discovering its boomerang nature, has now re-appeared in its brand new dress of Bolshevism with Russian trimmings. The leader seems to be a young American journalist, named Gale, who is said to have fled here, in 1918, to escape the draft. After stirring up the usual ruction in the recent strikes at Vera Cruz, at Tampico, Bolshevism is now face to face with the new government, and it is safe to predict that its heyday of trouble-making has come to an abrupt end.

IN EITHER vertical or inclined shafts, skips or cages must not be overloaded; and boards must not be placed across the top of skips and men permitted to ride thereon, unless a side-casing is provided as a protection, according to the mine-safety standards in Colorado. Guides or back-runners should be installed in all shafts when the inclination is more than 20° from the horizontal. Safety-catches should be used on man-cages or skips. These safety-catches should be inspected daily and tested once a month. When hoisting or lowering men at the beginning or end of shifts, special cages or skips should be used in all shafts where the angle of inclination from the horizontal exceeds 20°, and when the angle of inclination exceeds 30°, such cages or skips should be equipped with bonnets to protect men from falling rock. Safety-gates should be used on cages for hoisting men. Men should never be hoisted or lowered faster than 800 ft. per minute. Conditions may require slower speed for safety. Where buckets are used in vertical shafts over 100 ft. deep, cross-heads should be used. Where men ride on the buckets a suitable bonnet and safety-catches should be used on cross-heads. Cross-heads should be securely fastened to the cable. The guides of vertical shafts and the tracks and back-runners of inclined shafts should be inspected daily. Where inspection shows that guides or tracks have been shifted by moving ground, repairs must be made immediately. Wall-plates must be kept clear of accumulations of broken rock. Men should not be allowed to crowd around the shaft-collar or the station, previous to lowering or hoisting.

Some Controlling Factors in Flotation

By RALPH D. NEVETT

*The object of this paper is to offer some suggestions to assist metallurgists in supervising the operations of flotation plants. We do not yet thoroughly understand what 'flotation' is, or 'why minerals float'; all attempts that have been made to explain the phenomena have been based on theory or imagination, and have not been capable of substantiation by practical demonstration, or even by laboratory tests; but it is well known that particular minerals will float in a liquid under certain specified conditions, and that some other minerals will not float under those conditions, and that, if a mixture of the two classes of minerals be subjected to those conditions, there will be separation of the minerals, of which one class will float and the other will remain unfloat as a residue. The duty of the expert is to so control the operations and the conditions of the liquor as to obtain the best commercial result from the ore he is treating.

The chief controlling factors in a flotation plant appear to fall under the following eight headings, all of which are important:

- | | |
|---------------------------------|---------------------------------|
| 1. Crushing. | 5. Addition agents. |
| 2. Rate and regularity of feed. | 6. Condition of circuit liquor. |
| 3. Density of pulp. | 7. Agitation. |
| 4. Temperature. | 8. Aeration. |

CRUSHING

The ideal feed for flotation treatment is the true slime, which has been the bugbear of metallurgists throughout the ages. This fact should be remembered and taken advantage of wherever possible, although it would not be profitable, as a rule, to continue the crushing operation on crude ore to so great a degree as to make a slime of it. It may be generally accepted, however, that it is bad practice to have any particles remaining on a 40-mesh screen. This is not true in some exceptional cases, as sometimes, for instance, with laminated minerals such as molybdenite and certain copper ores.

Whether the degree of crushing is qualified by classifiers or screens, it is advisable for the metallurgist to assume personal control by having sizing-tests made on regular samples of the crushed feed. In practice it will be found generally that the undersize of a 20-mesh revolving screen, with 45% screening area when fully loaded, will almost entirely pass through a 40-mesh laboratory screen. An efficient crushing plant is the first essential for flotation treatment.

There are two reasons why the ore requires to be crushed so that all particles will pass through a 40-mesh screen:

*From the Proceedings of the Australasian Institute of Mining and Metallurgy.

1. Because the bubble of air or gas that becomes attached to a particle has not sufficient power to float larger particles of mineral which are produced by any other coarser crushing. If, moreover, a bubble of gas were large enough to float a larger particle, the resistance it would offer to the flow of the pulp would probably cause it to be wiped off and removed from the particle before it had time to reach the surface of the flotation bath.

2. Large particles of ore, when hurled around in the agitation zone of the flotation vessel, do considerable damage in hindering aeration by cutting bubbles of gas off other particles of mineral.

RATE AND REGULARITY OF FEED

It is essential that the rate of feed going into the flotation plant should be as nearly regular as possible each second of time. There is nothing that interferes so much with treatment as irregularity in the rate of feed and irregularity in the quantity of liquor passing through the plant from moment to moment. It is a simple matter to make the rate of feed and liquor regular by means of a large agitator or Dorr thickener placed at the head of the treatment vessels. This agitator or Dorr thickener can store quantities of feed supplied to it in an irregular manner by the preparatory plant and deliver it in a regular flow at its discharge to the treatment plant. This storage of slime also enables the flotation plant to be operated continuously through any small stoppages of the preparatory plant.

DENSITY OF PULP

It is necessary that the feed should be introduced to the treatment plant, in the form of pulp, at the pre-determined density best suited to the process. The density should be maintained at a regular rate from moment to moment just as strictly as the rate of feed itself.

Extensive experiments were made on the dump from the flotation plant at the Junction North mine for the purpose of determining a suitable density and rate of feed. It was found that variations of density had an important effect upon the rate of feed that could be treated. When the density was 56% solid, it was impossible to treat more than 8 tons of dump material per hour, and then only with poor metallurgical results. When the density was reduced to 35% solid, the same plant treated 24 tons of material per hour with excellent metallurgical results. This fact alone shows how easily a flotation plant can go wrong.

It will be seen from this that the rate of feed and density are allied with each other and complementary, and should be kept under constant control. The following is a quick and reliable method for controlling the density of the pulp in a flotation plant:

A tin is made to hold 1000 cc. of water up to a mark, say, about half an inch below the top. The tin is dipped quickly into the flowing pulp and filled up to the mark. It is then weighed, using a counterpoise for the tin. The shift-boss or operator should make such a density test at intervals not greater than 15 minutes. The weight of the pulp would be, say, 1350 to 1400 gm., which represents about 30 to 34% of solid in the pulp at the dump-treatment plant at the Junction North mine. If the weight is greater than 1400 gm., the operator adds water to the pulp as it leaves the Dorr thickener.

TEMPERATURE

On some ores flotation can be carried out in the cold, but a good many require heat to a limited extent. Sometimes, on ores containing several minerals, it is necessary to have a little heat for the flotation of one mineral and a greatly increased amount of heat for the flotation of the second mineral. At the dump plant at the Junction North mine in the selective flotation of lead and zinc sulphides by either the Bradford process or the Palmer-Seale-Nevett process, it has always been necessary to watch the temperature of the pulp very closely. In the lead section the most suitable temperature was 89° to 90°F. Even a single degree over 90°F. has been detrimental to the grade of the lead concentrate, as zinc sulphide commenced to float with the lead concentrate with the rise in temperature. In the zinc section the best results were obtained at a temperature of 135°F. with the Bradford process, and at a temperature of 125°F. with the P. S. N. process. If the temperature is allowed to drop to 130°F. in the former case, the zinc concentrate is not completely floated, and a loss is made in the residue. No benefit is gained by increasing the temperature above 135°F.

Metallurgists, wherever possible, like to treat the ores with as little added heat as possible, to save cost. Whenever heat is required, attempts are made to utilize the exhaust-steam of engines and similar sources of heat. It is not always possible, however, to make use of exhaust-steam in this way, even if it be available. The favorite method of heating, although perhaps the most expensive, is by the introduction of high-pressure steam direct from the boilers to the pulp, which is always convenient and easy to manipulate, and has quick and effective results, requiring only the operation of a valve from time to time for keeping the temperature of the pulp constant. The ease with which high-pressure steam can be obtained by the operator, and the fact that the extra temperature does no harm in zinc treatment, makes it liable to be wasted considerably. A close watch therefore must be kept on the steam consumption in this way, as it might, besides being wasteful in cost, tend to overload the boiler-plant if it is otherwise working at high pressure.

ADDITION AGENTS

In all flotation plants it is necessary to add some chemicals. The point at which such chemicals should be added is an important one, and should be determined carefully. It is a matter of vital importance that the valuable min-

erals in the pulp should be in a properly prepared condition suitable for floating before the pulp enters the machine. For the purpose of ensuring this, it is obvious that whatever chemicals are required should be added to the pulp at least before it reaches the flotation machine. Frequently the purpose will be served if the chemicals are added in the agitation machine, but sometimes it is advisable to add them to the pulp before that.

When acid is required, generally speaking the best place to add it is in the agitation machine, although it may sometimes be added directly to the flotation machine. Frequently acid produces gases, such as sulphuretted hydrogen, by action upon the pulp. These are harmful to flotation, and it is advisable to let them have time to disappear before the pulp reaches the flotation machine.

Oil is not an essential reagent in flotation, but when it is used it should be added far enough back in the flow to ensure its emulsification in the pulp before it reaches the flotation machine. When it is not thoroughly emulsified, oil is distinctly detrimental to flotation. Oil should never be added directly to the flotation machine, but may be added in the tube-mills or other grinding machines or in the return-liquor pump or in the agitation machine, as may be found best in practice.

CONDITION OF CIRCUIT-LIQUOR

Usually it is convenient to employ the ordinary mill-feed water for making up flotation circuit-liquor. The first essential is that this water shall be clean, that is, free from sediment. Such feed-water is usually drawn from the underground drainage system, to which has been added some fresh water from the surface supply. The mine-water would probably contain a certain amount of salts in solution, and in some cases the proportion of salts in solution would render the water unsuitable for flotation.

The mill-water coming in contact with the ore usually dissolves a good deal of the soluble impurities, and by the time the water reaches the flotation plant it might be too heavily charged with salts to make it suitable for acting as a flotation circuit-liquor.

The circuit-liquor requires some properties other than cleanliness to ensure its successful use in a flotation plant, but it is not clear what those properties are. For a long time it was thought that it was necessary to have at least a comparatively large definite quantity of salts in solution, and that this was the main controlling factor in the constitution of a good liquor for flotation. From many tests carried out at the Junction North mine, it would appear even yet as if the quantity of salts, and kind of salts, in solution exerted an important influence on the operation. It was noticed sometimes, when the flotation plants were not working well, that the quantity of salts in solution had either dropped below 1400 gr. per gallon or had risen above 2600 gr. per gallon. It would seem from the various tests that the best results were obtained when there were about 2000 gr. of salts per gallon in the solution. The salts were mainly salts of manganese, zinc, iron, and calcium. It would be a difficult matter to carry

out a set of tests either in the laboratory or in an operating plant to prove the effect of salts in solution. The ore itself, containing soluble salts, would, as soon as it came in contact with pure water, immediately provide some salts in solution.

A good deal of work has been done at the Junction North and by other investigators to endeavor to determine the actual effect of certain specified salts in solution, and much interesting information has been collected; but it has never yet been shown that any of the common salts that naturally go into solution in the Broken Hill treatment have a marked influence upon results, unless present in excessive quantities, and none of the salts known to exist in the circuit-liquors at Broken Hill have anything like so great an influence upon the treatment as to explain the reason why some flotation-liquors are energetic and others dull in their action. It is distinctly noticeable, when flotation work is going on successfully in the plant, that the liquor has some property which has never yet been thoroughly defined, and it seems to be a physical property denoting energy which has been instilled by some means into the circuit-liquor. Sometimes the nature of the liquor can be corrected by alteration in the oiling; sometimes by alteration in the application of acid. The new P. S. N. process claims to correct the conditions of the liquors in many cases by the addition of elemental sulphur.

If oil exists in the circuit-liquor, it must be emulsified. Free oil is detrimental to flotation work, as can easily be seen in the Cascade process. If a few drops of oil are admitted to the first Cascade vessel, its effect will be seen on each of the following Cascade vessels of the series in killing the float that was just previously there.

AGITATION

Agitation is beneficial in all methods of flotation on all classes of ore. Some, however, do not require so much agitation as others, and calcitic ores treated by purely acid processes usually require only a moderate degree of agitation before treatment. The quantity of calcite present in the ore need not be more than a few pounds per ton. The acid readily sets free the carbon di-oxide gas which, being nascent, rapidly attaches itself to the mineral particles and floats them. The intimate association of the calcite in the ore ensures successful gassing. Such ores as do not contain calcite or any other carbonates require treatment by agitation-aeration, by which the atmospheric air is beaten into the pulp, to cause the attachment of bubbles of air to mineral particles. The M. S. machine was originally designed for this purpose, and later on the Owen patent and Lyster patent showed other means by which it could be carried out more effectively and more completely. The agitation should be carried out in the treatment-vessel so that the mineral can rise to the surface of the vessel and be removed without having to travel a greater distance than is absolutely necessary, or, in other words, to avoid overtaxing the ability of the bubble to retain its hold on the mineral particle for leading it out of the flotation-bath. However, I am strongly in favor of providing some kind of machine at

the head of the treatment; for instance, a vortex mixer or an M. S. mixer, or a larger agitation machine, to provide that the pulp shall be thoroughly agitated and partly aerated before it enters the treatment-vessel. This pre-agitation aeration incorporates oils, reagents, acids, etc., and probably causes some beneficial effect by oxidation of some of the substances, and so saves the first treatment-vessel from being wasted on this work. It might be, too, that some deleterious substances are formed immediately upon application of the acid and reagents, such as noxious gases like sulphuretted hydrogen, which, in this preliminary incomplete agitation-aeration, are either driven off or altered to make them innocuous, and, in this preliminary agitation, chemicals or acid or perhaps oil may be added, the temperature being controlled so that when the pulp enters the machine it is ready for separation of the valuable minerals. It is even advisable to add the chemicals or oil or acid to the pulp before it enters the preliminary agitation machine.

With some simple ores very little agitation is required before the pulp passes to the flotation machine, and, in such cases, if the pulp is lifted by bucket-elevators direct to the flotation machine, sufficient agitation will be provided by the elevators for successful separation. In that case the chemicals and other reagents may be added, perhaps, at the foot of the elevator. The bucket-elevator may be looked upon as a first-class agitator, although the period of agitation provided by it is very short.

If the pulp requires much acid or heat added to it, it is advisable to have the agitation-vessel at the head of the flotation machine besides the elevator, because in such cases the elevator-belt would suffer severely if it handled hot or acid liquors.

Agitation is always beneficial to flotation, and in most cases it is absolutely necessary. It has a cleaning effect on the particles, and, if oil is used, causes a greater emulsification and distribution of the oil. To ensure a more complete flotation of the particles, it breaks up the bubbles of air and distributes them in a free state of division throughout the pulp in such a manner as to give every particle of mineral a chance to become attached to air-bubbles.

AERATION

Aeration means the introduction of air into the pulp in a finely-divided condition so as to form a froth, in order that the particles of mineral may become attached to finely-divided air-bubbles, by means of which they are buoyed upward to the surface of the flotation-bath and removed across the periphery as a separate concentrate. Air for aeration was originally introduced into the M. S. machine by being sucked down to the impeller from the surface through the vortex and disturbance caused by the agitation. The quantity of air so converted into froth was always indefinite and not under control, and for this reason flotation results were very changeable. It was necessary to have the agitation-aeration zone in another vessel separated from the flotation-bath, because the latter required a quiescent surface, which could not be provided by the former. This was a severe handicap,

as it required the bubble to travel a great distance before it could be rescued at the surface; consequently, only the most powerful methods of flotation could be used with it, such as would develop combined flotation and not permit of any selective action.

It was found by Owen that if agitation and aeration were carried out in the flotation bath itself the bubble would have a much shorter travel, and much more delicate flotation work could be carried out. The effect of this was to permit of selective flotation on one mineral in preference to another. By means of the Owen process, air was either sucked in by impellers or pumps, or was introduced as compressed air and delivered to the impeller in such a manner that it could be most effectively beaten up into a foam.

Later on, at the Junction North, it was found that definite control could be obtained to govern the quantity of aeration introduced into any pulp, and measurements could be obtained of the amount of aeration by means of a steelyard or an ordinary water-gauge tube, graduated and placed outside the flotation vessel and connected with it. It was found afterward, by means of the Cascade process, that aeration could be adequately obtained by means of entanglement of air with the pulp as it fell down open pipes.

It is essential that the air should be completely atomized in the pulp and not allowed to be distributed through the pulp in the form of comparatively large bubbles. This must be carefully watched when aeration by compressed air is adopted. If the supply of compressed air is too great through any one delivery pipe, then the air is distributed throughout the pulp in the form of large bubbles, which are unsuitable for flotation. These large bubbles rise rapidly to the surface and disturb the quiescent zone, so that some of the float already there is caused to sink again and some of the gangue is caused to overflow the periphery and spoil the concentrate. Compressed air must be added in such a way that it enters the pulp in the zone of maximum agitation of the impellers. The force of agitation at that point will determine the amount of air which may be effectively taken from the supply-pipe. If it is desired to atomize a still greater quantity of air than can be dealt with from one supply-pipe, it is possible to gain such an increase in any particular flotation machine by increasing the number of air-supply pipes around the impellers or by increasing the speed of the impellers.

In the Cascade process the air is drawn in and entangled by the pulp as it drops down the vertical pipe and becomes atomized by the splashing of the pulp in the impact, which occurs when the pulp hits the surfaces of the liquor and metallic parts of the flotation machine. It is generally advisable in the Cascade process to have a cup placed below the bottom of the vertical pipe to intensify the impact.

A NEW CLAIM for the record for rapid sinking of timbered shafts comes from South Africa. Of two new shafts at the New State Areas property, one was sunk 920 ft. and the other 1338 ft. during the past year. Both

shafts developed large quantities of water and progress was made under difficulties. At the south shaft a dolerite dike was intersected above the dolomite horizon. It weathered rapidly on exposure to the atmosphere; so to ensure safety the shaft was closely timbered, and the space between the dike and timber filled in with concrete, thoroughly reinforced. Since passing through the dolomite series both shafts have made rapid progress. The average rate of sinking for the first four months of 1920 was: north shaft, 225 ft. per month; south shaft, 247 ft. per month. The world's record for a timbered shaft till this year was 224 ft. in one month, but the south shaft had averaged a greater footage for four months, while an advance of 270 ft. in March exceeded the previous record.

Dust in Metal Mines

Dust in the air in metal mines probably causes more sickness and ultimately more deaths among miners than any other cause. In the opinion of experts of the Bureau of Mines any kind of dust will ultimately be harmful if breathed in large quantities, and this includes not only silicious dust, but coal dust, which some authorities believe has no harmful effect, lead-carbonate dust, and arsenical dust. The most harmful is probably free silica (quartz, flint, etc.) especially in the finer sizes. The hard, sharp, insoluble particles cut and injure the lung tissue, making it more or less inelastic and incapable of expansion, and ultimately bring on miner's consumption. It is probable that more than half of the common metal ores have a silicious gangue, or occur within silicious wall-rock. The finest dust, which is the most harmful, is invisible, and the dust is tasteless and odorless. It is chiefly raised in the air by dry drilling, blowing holes dry, blasting, shoveling, and tramming. The fine dust, once raised into the air, remains suspended many hours in still air, hence in poorly ventilated places the miners breathe this fine dust continually. By far the most dangerous condition is that of breathing dusty air in a hot humid stagnant place all day, and then going home in perspiration-saturated clothing through air frequently many degrees below zero.

Miner's consumption and lead-poisoning among metal miners are both caused by dust and are wholly preventable. The most effective prevention of dust in mine air, apart from elimination of dry drilling, is the circulating of pure air at the working face. Also, piles of broken ore should be wet down, and the timbers, floor, and walls of dusty working places should be sprinkled. The effectiveness of good ventilation in preventing miner's consumption is illustrated by two mining districts in the United States. In both districts the mines have cool rock and air and dry silicious ore easily broken into fine dust. In one district the method of mining requires constant shooting, so the mines all have moving currents of air at nearly all the working places; in the other, little or no air is circulating at working places. In the former, miner's consumption is practically unknown, in the latter it is a common disease.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

G. H. DOWELL OF THE COPPER QUEEN COMPANY TALKS OF
THE FUTURE OF BISBEE.

BISBEE.—A full face of sulphide ore, a general sample of which assayed 19% copper, has recently been exposed in the Boras mine. The importance of this find lies in the fact that this is the first sulphide ore found in this section of the district. It is possible that this discovery may tend to alter geological opinion as to the nature and depth of copper deposits and have considerable bearing on mineral operations in this section. The ore was found in a drift on the 600-ft. level of the Chance claim, west

Dallas and both will probably be housed under one roof. When completed the Dallas shaft will become the main hoisting-shaft for the Copper Queen, taking the place of the Sacramento, which will in time be caved as operations on Sacramento hill progress.

At a recent meeting of the Bisbee Luncheon Club, G. H. Dowell, manager of the Copper Queen branch of the Phelps Dodge Corporation, said in part: "The company that I represent depends largely on the income from this property for the development of other properties. As you all know, operations have been restricted during the last year or so on account of the inability of the company to market copper, but all look forward to a time

VENTILATING-STATION AT THE INSPIRATION MINE. FANS HAVE A CAPACITY OF 226,000 CU. FT. PER MINUTE

of the shaft, and every indication pointed to a big body of good sulphide ore. Considerable doubt has been expressed in regard to the possibility of finding sulphide ore in the vicinity of the White Tail Deer mine of the Copper Queen, where the Boras is situated. Development of the newly discovered orebody will be watched with keen interest. Prior to this find the Boras company had nothing but oxide and carbonate ores to ship.

The concreting of the Dallas shaft of the Copper Queen is progressing rapidly, about 21% of the work being already completed. Sinking to the 2000-ft. level is being pushed, and a tunnel is being driven for use as a conveyor-belt tunnel. The power-plant and hoisting-plant at the Sacramento shaft will shortly be moved to the

when we will be able to market all the copper we can produce. In addition to normal mining operations, there has been the work on Sacramento hill. The company has invested there already about \$5,000,000 and before the project is ready for operation will have invested more than \$8,000,000. I remember that a speaker here some time ago remarked that Sacramento hill is an illustration of the saying that faith will move mountains, but I have found that it takes something more than faith to move Sacramento hill. The project is really just begun. We have moved up to date about ten million tons but before the project is completed we will have to move more than 80,000,000 tons. The companies and the community here as elsewhere have the problem of labor supply. We have

had and have now all the labor we need under present production conditions. I think we will have enough when the time comes to arrive at a normal output, about eight million pounds of copper per month. It has been the policy of the company to employ English-speaking men underground. About 80% of those working underground are Americans. I hope the company will be able to continue this policy. On Sacramento hill the company has been forced to employ much Mexican labor, but you should understand that this is only a temporary condition. When the Sacramento Hill project is completed most of these will be laid off."

Residents of Douglas who were injured by flying bullets from across the line during the fighting at Agua Prieta in April 1911, last week received from the war department warrants in settlement of their claims. Five claims, amounting to a total of \$17,000, were paid. One claimant was injured by the shattering of window-glass in the residence of the superintendent of the Copper Queen smelter. These claims have been pending against the Government for nearly ten years. A commission, appointed by the secretary of war, investigated the claims in 1912 but it was not until 1918 that Congress included in the general war appropriation bill an appropriation of \$71,000 to pay in full the awards of this commission on the claims arising at Douglas and Bisbee.

JEROME.—Orders have been received to resume diamond-drilling operations at the Pittsburg-Jerome. The first drilling done will be to complete an underground hole which had been started when the shut-down came last spring. After it is finished, a 2400-ft. hole will be started from the surface. It is understood that the strike at the Shea is responsible for the decision of the Pittsburg-Jerome directors to resume prospecting.

A moving picture company is spending several weeks in Jerome in order to snap scenes for a new picture 'West is West'. The special feature to be filmed is a strike in what is known as the Torpedo mine in the story. Some of the pictures are being made in the streets of Jerome, others in the United Verde and United Verde Extension Mines, and the J. S. Douglas residence. Several of the scenes will be taken on the 1700-ft. level of the United Verde mine.

Just recently the short-line road from Prescott to Jerome, the centre of the rich Verde mining district, has been opened up for travel. Credit for this wonderful piece of highway work is due not only to the State and Federal authorities, but to the Yavapai County chamber of commerce which started to obtain this improvement and never stopped until the road was built. The old route over the Cherry Creek hill was 62 miles long, while the new road is 32. When the road is capped and gravelled, the running time will be about 1½ hours.

The Jerome-Superior has reached a depth of about 900 ft. and will sink 100 ft. more before starting lateral development. The surface equipment is ample for about 2000 ft. of sinking. It is reported that a new corporation, the Crater Mining Company, said to be an annex of the United States Smelting & Refining Co., has been formed to drill the famous meteor crater west of Winslow. Two

standard drilling-rigs have been purchased and will be erected near the inner edge of the 4100-ft. pit, with the expectation that the meteor plunged into the earth at an angle from the vertical. Exploration was conducted for a period of years by a Philadelphia company, that found great difficulty in handling the quicksand that filled in the great hole. Fragments of the meteor, however, were found, although it is believed that the main mass has not yet been found. The metal, as shown by analyses of the fragments within and around the pit, contained a remarkable proportion of nickel.

COLORADO

NEW DISCOVERY ON 1800-FT. LEVEL OF THE VINDICATOR
AT CRIPPLE CREEK.

CRIPPLE CREEK.—A rich shoot on what is believed to be the extension of the Lillie vein, has been entered at the 1800-ft. level from the Vindicator Consolidated company's No. 1 shaft on Bull hill. The discovery was made in virgin or undeveloped territory about 900 ft. south of the shaft station. The vein is a strong one measuring 8 to 12 ft. between walls and contains seams of sylvanite in quartz. The ore is reported to assay as high as 30 oz. gold per ton, while the general average of the sorted product assays from \$75 to \$150 per ton.

KOKOMO.—Organization has been effected of the Kokomo Mining Co. to operate the Pearl Consolidated group, formerly controlled by the late Charles J. Moore. Modern equipment is to be installed and development in charge of Stillwell Conner, who formerly operated in the Cripple Creek district, is planned. A mill will be constructed and plans are being prepared. A large tonnage of ore averaging 16 oz. silver per ton is on the dump and ore of higher grade is being developed by a tunnel and shaft.

MAYDAY.—A 35-ton mill, with modern equipment, is the consideration paid by W. B. Cauble, of Peoria, Illinois, for an undivided one-half interest in the Esmeralda group, in the La Plata district, to the owners, M. De Luche and George Smart of Durango. The material will be shipped from Denver and the mill construction will start as soon as plans are approved.

BOULDER.—Four distinct veins, all rich in silver, have been opened and are under development on the property owned by the Caribou Hill Mining Co., recently organized by W. W. Robinson, of Colorado Springs, and Denver associates. The company secured by purchase 14 claims, some adjoining the famous Caribou mine. Two shafts, one 200 ft. and the second 140 ft., are on the property but had not been worked for 20 years. They were in poor condition and half full of water when possession was taken. Samples of the ore taken from the workings of the No 2, or 140 ft., shaft were assayed with the following results: 1402 oz., 390 oz., 155 oz., and 584 oz. silver per ton. The claims are all patented and are among the oldest locations on the hill, but the owners had, through lack of funds, been unable to develop their properties.

BRECKENRIDGE.—The Blue Flag company has received

part of the equipment for its Laurium mill, and preparation has been made for installation of the ball-mill and flotation equipment on receipt from the Denver Engineering Works so that the plant can be in operation before winter sets in. The county boundary dispute, involving title to valuable molybdenum mines, which was originally decided in favor of Lake county, has been carried to the Supreme Court of Colorado by Summit county. Attorneys for Summit have petitioned that the writ of error be made a writ of supercedeas.

LEADVILLE.—The Fanny Rawlins Gold Mining Co. is producing an average of 10 tons daily with a force of 12 men. The ore shipped to the A. V. smelter averages about \$45 per ton in gold, silver, and copper. A second shift is to be employed. Sundry Leadville lease-operators have taken over the Gold Basin properties and are installing an electric hoist. Sampling of the vein has shown gold content as high as \$90 to \$100 per ton, as broken, with much higher value for sorted ore. The Gertrude mine in the Sugar Loaf district continues shipments of silver ore to the A. V. smelter. The mine is operated by lessees.

RICO.—July shipments from the Rico Wellington totaled 13 cars, of which 10 cars of lead-carbonate ore was shipped to the Midvale smelter in Utah, and two cars of lead-zinc ore to Coffeyville plant in Kansas. One car of pyrite was consigned to Vanadium, Colorado. Work has been resumed by local mining men who have a lease and bond on the Union Carbonate property, that has been inactive for many years, but when last operated produced a good grade of ore. The Rico Argentine has secured contracts for the sale of its lead-zinc ore and is shipping steadily.

IDAHO

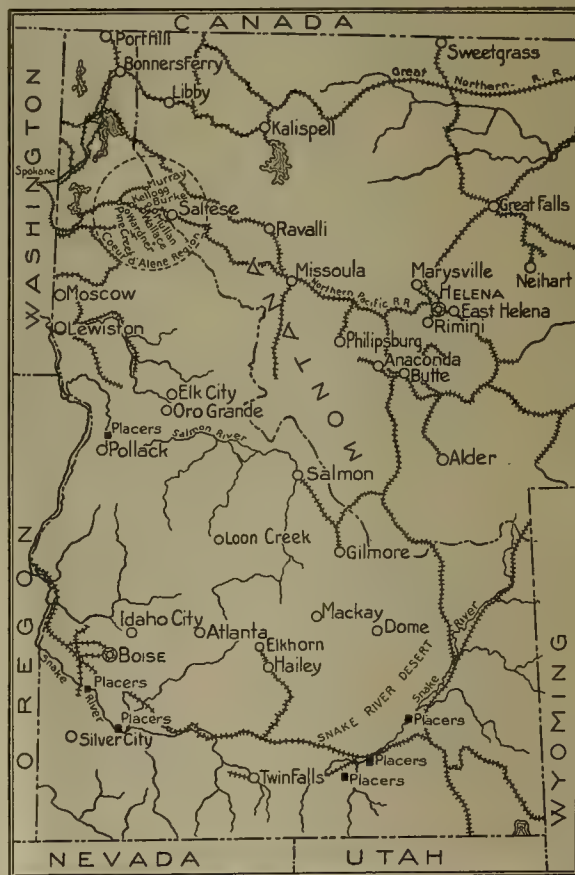

ENCOURAGING DEVELOPMENTS IN UTAH-BELLEVUE MINE, WOOD RIVER DISTRICT.

BELLEVUE.—Assays of ore taken from a drift on a vein traversing the property of the Utah-Bellevue Mines Co. indicate rich ore, according to Joseph H. Saxman, manager, some being as high as 27% lead, 198 oz. silver, \$8.80 in gold, and 16.5% zinc. The lowest sample result was of \$1.20 in gold and 51.4 oz. silver per ton. The Wood River district, in which the Utah-Bellevue property is situated, is one of the oldest in the State. The principal development at the property consists of an incline shaft, sunk to a depth of 108 ft. Although a vein from 2 to 8 ft. wide was opened and some shipments made, the company decided to develop the ore at greater depth by driving a cross-cut tunnel. Within a distance of 500 ft. several high-grade ore-shoots have been cut, according to Mr. Saxman. Recently a connection between the drift and incline was for better ventilation.

CLAYTON.—Robert N. Bell has secured a long-term lease on some mining property at Clayton. Within a short time, it is stated, he and his associates will erect a 50-ton mill for the purpose of treating the low-grade ores in the 'Red Bird' property. Speaking of the mining situation generally in the State, Mr. Bell says the scarcity of

labor and the tightness in the money market have proved serious drawbacks to progress, but that the labor situation was easing considerably, so that he anticipates no trouble in finding miners for his work.

COEUR D'ALENE.—The Tamarack & Custer Consolidated Mining Co., on Nine Mile, is operating with 250 men. It is reported to be producing 3000 tons of lead-silver ore monthly. The Hercules Mining Co. is operating with 600 men, 300 on each shift, and shipping 6000 tons of ore per month. The Friend Mining Co., on Beaver creek, declares that lead ore is taking the place of zinc in the drift from the 50-ft. shaft. The drift is in 20 ft. in an 8-ft. vein. The ore has changed from nearly

MAP OF IDAHO

all zinc to about three to one in favor of lead. The three-compartment raise being driven by the Nabob Consolidated company has attained a height of 112 ft. above the main-tunnel level. The purpose of the raise is to provide an outlet for ore developed on the Sidney and Denver tunnel-levels of the Nabob property, but in the course of work considerable ore has been developed. The Hecla Mining Co., at Burke, will disburse its regular quarterly dividend of \$150,000 on September 28. This is at the rate of 15c. per share on the issue of 1,000,000 shares. The company is hoisting from 600 to 700 tons daily and shipping from 2500 to 2800 tons monthly.

MICHIGAN

HANCOCK CONSOLIDATED IS HOLDING WATER IN ANTICIPATION OF RESUMING WORK.

CALUMET.—The recent advances in freight-rates add to the worries of the Lake Superior mine-owners, who are struggling with the burden of a demoralized market, high cost of coal, labor-shortage, and increased cost of materials entering into mining. The rate advance is a major problem. In the case of Calumet & Hecla it will add approximately \$40,000 to its coal bill, besides increasing by 35% the cost of hauling 'rock' from the subsidiary mines. Calumet & Hecla has just shipped 1300 tons of billets and ingot bars to Montreal, en route to France. Included in the shipment were a few carloads of copper that had been stored on the old Lake Superior Smelting company's docks at Dollar Bay for more than two years. This was the first copper taken from the 13,000,000-lb. stock since 1918. Steel is on the ground for the addition to Calumet & Hecla's flotation plant, and it is expected that by early winter the two units which the extension will house will be in operation. Accordingly there will be no large increase in the flotation-plant production until next year. The present output of the reclamation plant is at the rate of 16,000,000 lb. per year. Calumet & Hecla has transferred its crew of miners and trammers from No. 16 to No. 15 shaft of the Osceola lode, the former having suspended work. For upward of two months No. 16 has been operating only one shift, with a force of 40 men, as compared with a normal of 60. A few Centennial men have been taken on in No. 15, so the suspension of No. 16 will make little difference in tonnage.

The Copper Range group—Champion, Baltic, and Trimountain—holds production nearer normal than almost any other company on the Lake. While the Copper Range organization suffered early in the year, the output of refined copper indicates that progress is being made in face of adverse circumstances. The production in July was approximately 233,000 lb., for Trimountain, 500,000 for Baltic, and 1,200,000 for Champion. This is even better than early in the year for Baltic and Champion, but slightly below the production six months ago for Trimountain. The yield for Champion in July was 45 lb. per ton, 36 for Baltic, and 30 for Trimountain. This is an increase of from three to five pounds for Champion and two pounds for Baltic, compared with the past six months, while it is normal for Trimountain. Champion is not operating with as many openings as a year or two ago, although developments at the Baltic property are well ahead of the corresponding period of 1919. New openings are being pushed with greater speed at Trimountain. Baltic's principal openings are in the south end, in No. 2 shaft, and all through the West lode. Copper Range still has about four months' supply of copper on hand, or nearly as much metal as at the beginning of the year. There is little possibility of a shortage of fuel at the Copper Range mines, for assurance has been given that cargoes will arrive at regular intervals, with sufficient fuel to carry the mines, rail-

road, and smelter until spring, when a general improvement in conditions is expected by the operators.

Hancock Consolidated is keeping its shaft pumped out in anticipation of an order to resume operations, but it is likely that no attempt will be made to begin actual mining until there is a considerable improvement in market conditions. With fuel-costs at high levels and the mine only on a development basis, Hancock is saving money by remaining idle. Hancock is well financed for operation, for the bond issue authorized by the shareholders at the annual meeting in July took care of indebtedness and provided a comfortable surplus for the future. The mine is well equipped and the yield has been around 17 lb. per ton. While this is sufficient to pay expenses normally, only production on a large scale gives promise of making a dividend payer.

Seneca's shaft has approached a depth where the driving of a cross-cut will begin. About 60 ft. must be driven. The north drifts on the third and fourth levels have reached a length of slightly more than 600 ft., while the fourth level, south, is near the Ahmeek boundary. The ground to the north has improved materially. In fact all three faces are in good ground. For the time, drifting only will be done as each level is reached and by the time the mine is opened to the 8th, the openings, it is expected, will be sufficiently large to make possible a daily production of 5000 tons of ore. This will be possible by operating on four or five levels simultaneously and this will entail the use of an unusually large hoist and skip. The 13th level drift, south, at Gratiot, something over 650 ft. long, shows consistent improvement and in this respect is fulfilling expectations.

NEVADA

REDMOND CONSOLIDATED COMPANY OWNS PROMISING GROUP OF CLAIMS NEAR LUNING.

LUNING.—Four miles north-west of here are 15 claims owned by the Redmond Consolidated. They are 3500 ft. above Soda Spring valley, but are easily reached over a good road. Five of the claims were bought in 1915 by A. A. Redmond, interested in the Five to One company at Goldfield, and the others were located by him. Before Redmond took over the claims \$750,000 worth of ore had been shipped from them and there is now blocked out or partly so, above the 300-ft., or bottom level, 65,000 tons of ore of an average value of \$20, according to a report made by Leon M. Hall and Edward A. Southworth. The formation is principally lime-shale, with numerous intrusions of dark-gray porphyry. There are five parallel fissure-veins that can be traced north-east for two miles, or from the crest of the range down the slope toward the valley. These veins dip north-west and, although they are prominent, the width can only be determined definitely in the mine, where on the 100-ft. level vein No. 3 is 70 ft. wide. The outcrop of the veins indicates a width of 50 to 200 ft., with 150 as the average. Some of the ore contains copper and there is a gray-copper vein-capping at several places. The orebody from which the \$750,000 production was made was 500 ft. long and 3½ to 12 ft.

wide. It was stoped to the surface from a depth of 135 ft. Much of the ore in the dumps assays \$20 in the proportion of three parts silver to one of gold. The work was confined almost entirely to vein No. 3, on which there is a 300-ft. vertical shaft, with 6000 ft. of laterals, raises, and winzes from it. Most of the work was done between the 100-ft. level and the surface and three shoots were mined, one on each wall and one in the centre of the vein. Practically all of the ore came from the centre shoot, although a stope 40 ft. long and 6 ft. wide extends to the surface on the foot-wall. The average value of all of the ore mined was \$35 per ton, according to the report. It was treated in a mill eight miles from the mine. The report says the three ore-shoots merge on the 300-ft. level and that a drift has been driven 42 ft. in ore at this depth. A 20-ft. cross-cut from the hanging wall also is entirely in ore. It is estimated that for \$50,000 a tunnel can be driven from the valley to cut the veins at depths of 1000 to 2500 ft., including the cost of machinery. A spur track from the Southern Pacific main line can be built on an easy grade to the tunnel, the report says.

DIVIDE.—The Gold Zone has opened 15 ft. of \$16 ore in a cross-cut on the 700-ft., or bottom, level. The vein in which the ore is found is said to be 175 ft. from the extension into the Zone of the Tonopah Divide vein, which is the objective of the cross-cut. This discovery, with recent finds in the Tonopah Divide and the announcement that the Hercules and Giant, Wingfield companies, are to resume work, has caused optimism among those interested in the district. Good reports, verified by disinterested engineers who have been in the mine recently, continue to come from the Tonopah Divide. It is said that much good ore is being found on the fifth level in a vein parallel to the main vein.

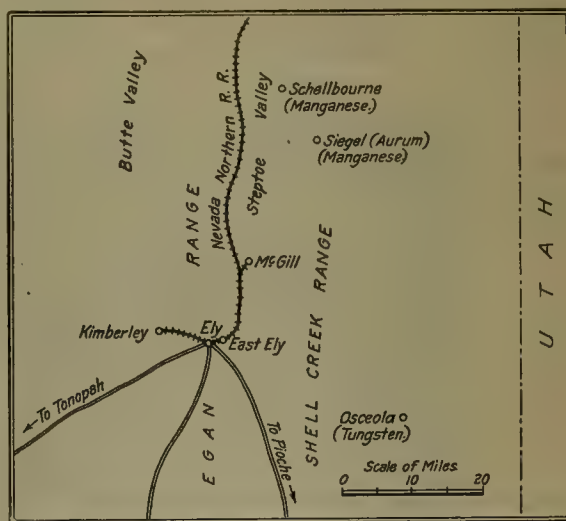

CARSON.—Representative mining men of the State attended the intra-state rate hearing of the Public Service Commission and petitions were received by the commission protesting against increases in railroad freight-rates. It is reported that the commission will deny the application of the railroads for permission to raise rates, as it is the opinion commonly held that an increase would mean disaster for the mining interests of the State.

ELY.—The Siegel, on the west side of Spring valley, is to be closed if railroad freight-rates are increased. The Siegel is a shipper of silver ore containing manganese and there is blocked out 100,000 tons of ore with an average silver content of 25 oz. The manganese content is as high as 25%. Some of the shipments have contained 200-oz. silver ore. During the quarter ended July 30, the Nevada Consolidated treated 691,095 dry tons of ore assaying 1.47% copper, as compared with 685,944 tons assaying 1.34% in the preceding quarter. The income, after deducting depreciation charges, was \$384,000, or 19c. per share. The cost of production, including fixed charges and administration expense, was 15.56c. per pound, as against 20.72c. in the preceding quarter.

TONOPAH.—The Rescue is driving a cross-cut on the 1100-ft. level in a vein cut recently near the Belmont boundary line. The cross-cut is being driven from the

foot-wall and the opposite wall has not been entered, but indications are that the find is of much importance.

GOLDFIELD.—The drift being driven by the Kewanas on the 825-ft. level of the Merger shaft toward the St. Ives vein in leased ground has been advanced 85 ft. The St. Ives vein is parallel to the Consolidated and the part the Kewanas will prospect has produced well from a depth of 300 ft. to the surface. The vein should be cut in 450 ft. The Kewanas has a four-year lease from August 1 and will pay a royalty of 15% to the Deep Mines after

ELY DISTRICT, SHOWING SIEGEL MINE

freight and treatment charges have been deducted. Nicholas P. Theo, secretary and treasurer for the California Excelsior Oil Co., now drilling in Fish Lake valley, his brother, A. P. Theo, and others have been indicted on a charge of using the mails to defraud in connection with the affairs of the Cuprite Sulphur, a company that formerly operated at Cuprite, south of Goldfield. The indictment was returned in the Federal Court of New York. Nicholas P. Theo was arrested in Goldfield and was taken to Carson by a United States deputy marshal. He was arraigned in the Federal Court at Carson and released on \$3000 bail. Fish Lake valley, in western Esmeralda county, is the scene of the latest exploit of the Theo brothers, this time in what is said by some to be an 'oil-field'.

MINA.—Demonstrating the continuity of the hanging-wall orebody from the sixth to the seventh level in the Simon Silver-Lead mine, and indicating that the present ore-reserves will be almost doubled, the recent strike of high-grade milling ore in the raise from the lowest level is important. Ore has been followed in the raise for approximately 100 ft. and any round of shots should break through to the sixth level. Three mill-sites have been surveyed to determine the one best suited for the proposed new flotation plant, the first unit of which will treat 100 tons per day. The engineers are also engaged in examining the foot-wall territory adjacent to the mine with a view to selecting the spot for the new shaft.

UTAH

SMELTING COMPANIES INCREASE THEIR CHARGES AS A
RESULT OF NEW FREIGHT-RATES.

SALT LAKE CITY.—Notices have been sent to ore-shippers by the various smelting companies, advising that treatment-charges will be raised to meet the increased freight-rates on bullion shipments. Effective August 26, there was an increase of $33\frac{1}{3}\%$ in the freight-rates on lead bullion and blister-copper from Salt Lake valley smelters to the Atlantic seaboard. In accordance with a provision in the contracts, the smelting companies have the privilege of making deductions from metal quotations to cover this increased cost. These additional deductions amount to 0.25c. per pound for lead, 0.25c. per pound on copper, and 1c. per ounce for silver. It is further announced by the smelting companies that in case the freight advance announced should be modified by the railroads, their deductions will be changed accordingly.

Fifty ore-handlers, employed at the Murray plant of the A. S. & R. Co., went on strike August 21. The men demanded a general wage increase of 50c. per day. J. M. Bidwell, manager of the Utah department of the company, states that operations were not seriously interfered with and that by August 25, practically all of the strikers had returned to work.

In a decision handed down on August 24, the Public Utilities Commission of Utah refused to permit the railroads of the State to increase freight charges on shipments of coal and ore.

BINGHAM.—During the first seven months of the present year, the Bingham Mines Co.'s earnings, including those from its 95% equity in the Eagle & Blue Bell mine at Eureka, were \$330,803, or \$2.20 per share, before allowing for taxes and depreciation. After deducting all charges, the net earnings were \$222,783, or \$1.48 per share, equivalent to an annual rate of \$2.55 per share. During the corresponding period of 1919, the company showed a deficit of about \$4000 per month.

ALTA.—Shipments of ore from the Columbus-Rexall mine are bringing good returns, according to R. M. Evans, manager. A recent consignment of four cars assayed 33.7 oz. silver, 13.2% lead, 3.85% copper, and 9.2% zinc, with a gross value of \$55.43 per ton. Production at the mine, while steady, is somewhat curtailed due to the prevailing shortage of labor, which is handicapping operations at nearly all of the mines in this district.

PARK CITY.—Probably the best ore yet developed in the Keystone mine has been opened recently. The ore carries approximately 40% lead and 15 to 20 oz. silver, making it worth \$60 to \$70 per ton. The new shoot is being developed in the No. 3 level from the Kearns and Keith shaft, at a depth of about 1000 ft. The Keystone company operates through part of the K. & K. shaft. For the last 125 ft. No. 3 drift has been following a fissure which has carried some ore most of the way. The main-tunnel level has been extended along the strike of the ore for 25 ft. without getting out of ore. The ore was

found making in a lime bedding and a drift was run at right angles to the main-level drift into the bedding. This drift has entered the bedding for a distance of 40 ft. and has been in ore throughout its entire length.

Work was suspended temporarily at the Ontario property recently to permit the installation of a larger pump on the 2000-ft. level, owing to the heavy flow of water. Frank Fleishman, superintendent, reports conditions as favorable on that level and improving all the time. During the week ended August 21, eight mines in this district shipped 2279 tons, as compared with 1776 tons shipped by six properties during the previous week. The Ontario shipped 623 tons; Judge M. & S., 483; Silver King Coalition, 478; Daly-West, 178; Daly Mining, 158; Naildriver, 120; Park-Utah, 51; and Keystone, 110. The Judge smelter shipped 78 tons of premium spelter.

EUREKA.—Mining companies in this district shipped a total of 129 cars of ore during the week ended August 21, as against 122 for the previous week. The Chief Consolidated shipped 34 cars; Tintic Standard, 28; Dragon, 12; Iron Blossom, 10; Mammoth, 9; Eagle & Blue Bell, 8; Iron King, 5; Grand Central, 4; Swansea, 4; Victoria, 4; Centennial-Eureka, 3; Gemini, 3; Tintic Drain Tunnel, 2; Bullion-Beck, 2; and Empire, 1.

A large map of the Tintic mining district, which has been under compilation for a number of months in the office of A. C. Burritt, mining engineer of Salt Lake City, has been completed. The map is seven feet long and covers the entire district from the Knight drainage-tunnel on the south to the Greeley and Utah-Standard groups on the north; and from the eastern limits of the Tintic Standard to the North Beck and North Gemini on the west. Small prints will be available as soon as the plates can be secured.

Jackson McChrystal, manager of the Gemini and Ridge & Valley mines, reports new work at both these properties. From the 1600-ft. level of the Ridge & Valley a raise is now being driven through promising ground. Small bunches of ore have been found that promise important developments.

Recently a small group of employees at the Eagle & Blue Bell mine endeavored to call a strike, but the movement was a failure. The disgruntled employees made a demand on William Owens, superintendent, for a raise in wages, a larger change-room and lockers, and that no tools be lowered on cages carrying men. The day-shift at the property remained at work, and the trouble was caused by part of the night-shift. Mr. Owens states that no tools are carried on cages along with employees, and that no mining company in the State is more anxious to safeguard its employees than he. Officials state that the present is a most inopportune time for considering wage increases; that every mining company is having its share of trouble, and profits have been cut and slashed by increased operating costs and decreased metal prices. The peak of operating costs has evidently not been reached, as increased freight-rates will make it difficult for many of the smaller properties to weather these difficulties.

At a meeting of the stockholders of the Godiva Mining Co. on August 21, it was voted to accept the proposition

for the sale of the entire holdings of the company. It is understood that some of the older stockholders will retain their interest in the company, but the control will go into other hands. It is expected that the new company will undertake extensive development. At present the deepest working in the mine is a winze that was sunk 150 ft. below the 1200-ft. level.

BRITISH COLUMBIA

TITLE TO GRANBY CONSOLIDATED COMPANY'S CASSIDY COLLIERY IS CLOUDED.

VANCOUVER.—In giving judgment in favor of the Esquimalt & Nanaimo Railway Co. in the case of the rail-

other lands by the Dominion government as a part consideration for building the railway, and that the Provincial government had no right to crown-grant the land. The case will be appealed, and the Granby company will be allowed to work the property, which is outputting 500 tons of coal daily, until judgment is given at the court of final appeal, the Privy Council. About two-thirds of the production of the colliery is used for making coke for the Anyox smelter and the remaining third is sold for domestic purposes.

PRINCE RUPERT.—Four days of almost continuous heavy rain following closely on another storm that had completely saturated the ground played sad havoc with

A NEW PICTURE OF BINGHAM CANYON. UTAH COPPER MINE IN THE BACKGROUND

way company v. Wilson & McKenzie, on August 24, Justice Gregory finds that the Granby Consolidated M. S. & P. Co. loses its title to the land on which it has developed and equipped its Cassidy colliery at a cost of more than \$2,000,000. The Granby company purchased the property from Wilson & McKenzie, executors to the estate of the late Joseph Ganner and Mrs. Dunlop. The original owners had received the property under the Settlers' Right Act, and were in possession prior to the building of the railway. After purchasing the property, the Granby company applied for and received a crown grant to the coal lands. On February 18, 1918, the railway company brought suit to have the crown grant made null and void, claiming that the land had been given to them with

railroads in the Portland Canal and Alice Arm mining districts. Four bridges on the Portland Canal short line, crossing creeks tributary to the Bear river, were washed away and in several places the embankments were badly eroded. The Salmon River wagon-road, too, suffered badly from the effects of the storm. Several embankments were damaged and in places considerable earth was washed onto the Alice Arm-Dolly Varden railway. This, however, has been repaired and ore-trains are moving again. The damage to the Portland Canal line, which only recently had been repaired and put in running order by the Algonquin Development Co. for the purpose of taking supplies to the Fitzgerald group, which the company had under option, is of a more serious

nature, and it is doubtful if the line can be operated again this season. The damage affects a number of other properties that were using the line, but parties interested have expressed their intention of continuing operations, notwithstanding the disadvantage under which the storm has placed them. A Victoria syndicate has bonded the Dunwell group, on Glacier creek. A five-foot vein has been stripped for 300 ft. and is said to average \$20 per ton in gold, silver, and lead. A new strike has been made at Rivers Bright, at the northern end of Princess Royal island, and 14 claims have been staked. The vein is said to be 40 ft. wide, heavily mineralized, and similar to the Surf Inlet mine ore. The Granby Consolidated M. S. & P. Co. produced 2,400,000 lb. of copper during July, against 2,079,000 lb. in June. This is the first month's work under the new management, and the increased output is said to have been made with a decreased consumption of coke and flux. The company is said to be planning the erection of a 2000-ton concentrating plant, with a view to concentrating the ore and smelting the concentrate in future. The Hidden Creek ore is low grade, and in the past has taken considerable quantities of coke and fluxes to smelt it. For example, last year 647,466 tons of ore required 41,000 tons of limestone, 36,000 tons of quartz, and 56,500 tons of coke, and gave a yield of 19,544,588 lb. copper, 348,408 oz. silver, and 4864 oz. gold. J. H. Meenach, of Seattle, who has the Musketeer group under bond, has stopped work for the season. The new compressor has been erected at the North Star mine, but a shortage of oil-fuel has delayed its being operated.

ONTARIO

NEW ROLLING-MILL PLANNED AT SUDBURY BY THE INTERNATIONAL NICKEL CO.

SUDBURY.—The International Nickel Co. is planning the construction of a new rolling-mill at a cost approximating \$3,000,000, to be used exclusively for the rolling of monel metal, which is now done at Bayonne, New Jersey. This is understood to be another step in the direction of carrying out all the operations of the company in Canada. The company at present employs 2500 men and is mining about 3000 tons of nickel ore per day, or less than half the capacity of the plant. It is now completing a dam at High Falls, 90 ft. in height, which will hold the water back for a distance of 25 miles to secure a supply of electric power.

PORCUPINE.—Last week the town of South Porcupine was in imminent danger of destruction from a devastating forest fire, which raged for several days in the immediate neighborhood. The place was only saved by the desperate exertion of the residents who fought the flames continuously for two days and nights until a heavy rain-fall brought relief. No reports of damage to mining properties have been received.

The Hollinger Consolidated has found gold at a depth of 2400 ft. in a drill-hole sunk from the 1250-ft. level. The gold content was not high but an encouraging circumstance is that the core of the drill shows that the geological formation on the 1250-ft. level continues at

depth. The sinking of the shaft to the 2500-ft. level is being continued. The working force now numbers about 1200 and new men are being taken on every day. One hundred British miners are expected to arrive in September. The company has declared a special dividend of 1% payable September 8, which gave rise to the impression that it had resumed the payment of four-weekly dividends. It is officially stated, however, that the company has no present intention of the kind, but is merely paying dividends as the earnings accumulate.

The Davidson has made important financial arrangements in England by which \$1,125,000 has been secured for a program of development, including the sinking of a 3-compartment shaft to a depth of 1000 ft. and the construction of a mill with a daily capacity of 1000 tons, the first unit of which will handle 500 tons daily. It is estimated that a working capital of \$300,000 will also be available. The English interests are to receive a block of 1,500,000 shares of treasury stock at 75c. per share on which a substantial payment has been made, the entire amount to be paid by April 1, 1921. The purchasers also receive an option on 1,000,000 vendor's shares at \$1 per share, and 1,000,000 more at \$1.25.

The sinking of the shaft on the Keora has been considerably delayed by a heavy flow of water but the difficulty was successfully overcome and the 250-ft. level reached. Cross-cutting has been started to open up high-grade ore deposits.

The directors of the Dome Mines have decided to take up the option on the Dome Extension on a basis of one share of Dome Mines for every 30 shares of Dome Extension. A meeting of shareholders has been called for September when the proposal will be submitted for ratification.

COBALT.—The recent advance in the price of silver has resulted in increasing the output of the Cobalt mines. Shipments last week amounted to 565,193 lb. of ore and 274,837 oz. of bullion. There is less unrest among the miners and if satisfactory conditions continue a largely augmented production during the remaining months of the year is anticipated.

The recently discovered vein on the Bailey, 1½ in. wide of milling ore, has widened out to 5 in. with an increase in silver content to 1500 oz. per ton. It promises well as the find is at the contact.

BLUE MOUNTAIN.—The old mica mine near the head of Stony Lake, Peterborough county, has been purchased by C. L. Nicholson, of New York, and Norman Miller, of Michigan, who will begin operations shortly and expect to ship 100 lb. of mica per day.

HYLA.—The American Molybdenite Co. has purchased three feldspar properties at Hyla, Haliburton county, and made contracts with a manufacturer of sanitary enamelware in Ohio for the delivery of 35 tons of feldspar per day with a prospect of largely increasing this amount when the equipment now ordered has been installed. It is stated that the feldspar deposits in New England, from which supplies have hitherto been drawn, are becoming exhausted, and that new sources of supply ore sought.

THE MINING SUMMARY

SMELTING-CHARGES ARE INCREASED

The following is quoted from a notice issued by the American Smelting & Refining Co. at Denver. The same policy will be followed with respect to the various plants of the company in other States.

"The general increase in railroad freight-rates allowed by the Interstate Commerce Commission, effective August 26, 1920, adds 33½% to the tariff on smelter products; that is, lead bullion and copper matte shipped to refineries, and 35% on shipments of fuel and lime-rock from mines and quarries to our smelting plants. These advances in freight-rates affect, furthermore, the cost of material such as steel, machinery, electrical equipment, etc., used in the operation, and increase the charges for switching intermediary products within the plant. In addition the refining plants have increased charges in proportion to their increased cost.

"The smelting industry of Colorado, already handicapped with refractory ores, high labor costs, and the rapidly mounting costs of fuel and materials, cannot bear this added burden without adjusting metal-deductions and treatment-charges in proportion to the increased freight-charges.

"On lead the deduction from New York sales price will be 27½c. per hundred pounds in addition to the present 50c. deduction and is directly proportionate to the increased freight-rates. This will be effective on all ores shipped on or after August 10, on the assumption that the bullion resulting from the smelting of these ores will not be shipped until after August 26. As a matter of fact the time consumed in the smelting process is from 30 to 60 days, the smelting company suffering a loss on all of its present lead stock.

"The deduction from the electrolytic wire-bar-copper quotation will be 4.7c. per pound, covering increase in freight-rate which on 40% copper in the matte amounts to 83½% raise in the metallic copper contents, the balance being increased refining charges. This change is also effective on shipments on and after August 10 for the same reason as indicated above in connection with lead.

"Treatment charges on all ores except oxidized iron fluxes carrying over 30% excess iron received on and after August 26, 1920, will be increased 50c. per ton.

"It is hoped that with the prospect of a steady silver market and improved lead and copper prices and with the closest attention on the part of the mine and smelter to efficiency in operation, that the mining and smelting industries in Colorado will be able to maintain operations throughout this trying period."

ALASKA

Juneau.—During the second quarter of the current year, the Alaska Gold Mines Co. milled 537,754 dry tons, as against 625,890 dry tons for the first quarter. The gross value of the ore was 85c.; the yield was 68c. and the tailing 17c. During the period 646,327 tons of ore was broken in the mine, principally from stopes on No. 8, 9, and 11 levels. A total of 402 ft. of development work was done, consisting of man-way drives and bull-dozing drifts in connection with opening up new stopes. Owing to scarcity of labor, the mill was operated with two shifts in the crushing department, and the concentrating department on a three-shift basis. The number of employees averaged 450 for the quarter, as

against 560 for the preceding quarter. The gross value of the bullion and concentrates produced was \$364,866; total expenses were \$426,537; loss for the quarter, \$61,670, as against a loss of \$84,585 for the preceding quarter.

CALIFORNIA

Amador County.—The Kennedy Mining Co., whose property is near Jackson, has decided not to make any attempt to unwater its mine and all men, except watchmen, will be laid off immediately. The Argonaut company continues to pump water but under the recent order of the Railroad Commission no hoisting of water in tanks is allowed.

Nevada City.—The order from the Railroad Commission curtailing the use of power for mines in Grass Valley and Nevada City has in no way been changed, although a very determined effort was made on the part of the superintendents to have the order modified to such an extent that the mines could operate on a reduced basis. Even this request was denied, although all are allowed sufficient current to hoist water. The only hope of returning to former conditions rests in early mountain storms. Everyone knows that full resumption is out of the question because of a shortage of labor.—P. F. Roosa, of Washington, D. C., has been in Nevada and Sierra counties interviewing chrome producers who have filed claims for losses incident to the signing of the Armistice.—The Boundary Mines Co., which is erecting a mill just west of the town of Grass Valley, has bought the power-plant at the Osborne Hill mine and is engaged in removing it to the new foundation.—The New England and Sligo quartz claims at Gold Flat near here, have been sold by John V. Hunter and Mrs. C. D. Vincent of San Francisco to the Nevada County Bank.

San Francisco.—C. H. Fry, engineer for the California Metal and Mineral Producers Association, advises operators that they submit in writing any protests or suggestions that they may desire to bring to the attention of the Industrial Accident Commission apropos of the 'Mine Safety Orders' which are to be finally approved on September 17. A public hearing, attended by about 20 mining men was held two weeks ago and a number of suggestions made, which were adopted by the Commission. Any communications received prior to September 17 will be given consideration. Copies of the tentative orders were distributed among the mine operators some months ago.

COLORADO

Mayday.—Curtet & Moigg, lessees on the Southern Boy, have completed their cross-cut, having penetrated the ore-body for which they have been driving during the past eight months. The vein is 1 ft. wide and assays 2 oz. in gold.—The Mayday Leasing Co. continues operations on the Mayday dumps. Two cars have been shipped to the Durango smelter. The screenings show a value of \$16 to \$28 with some crude ore assaying as high as \$70 per ton in gold and silver.—The cross-cut at the Ruby Gulch has opened two veins, one 4 in. and one 1 ft. wide. The small streak is expected to be rich in gold and silver, as it assayed 100 oz. gold and 200 oz. silver near the surface.—The Jumbo continues shipping from the 800-oz. silver vein recently found in the raise. Another raise is being driven to explore the fissure-vein in the lime strata at the contact.—W. A. Becker, manager of

the Little La Plata and Boren Gulch, is having a compressor installed at the Boren Gulch. Operations at the mine, which discontinued last fall, will be resumed as soon as the compressor is in place. The cross-cut at the Little La Plata, which has been driven continuously since last winter, has not proved as beneficial as was expected. Part of the force employed in driving this tunnel, has been put to work on the vein at the surface, from where lessees have made shipments of ore.

MONTANA

Cooke City.—A fleet of 21 trucks is now hauling ore from the Republic company's property, to Gardiner, where it is loaded into railroad cars. There is more activity in the district this year than ever before. At the McKay properties, the Yellowstone, the Republic mines, Glengarry properties, and Western Smelting & Refining holdings, work has been done in spite of a shortage of miners, and encouraging results are being obtained from development.

Neihart.—Ore shipments are being made at regular intervals from all the mines in the district, with the exception of the Neihart Silver Mines, where all available men have been put on development work. One car of ore has been shipped from the Silver Dyke and another is now being loaded. The Neihart Consolidated has a couple of cars ready for shipment and the Molten is loading a car. Several lessees are working and nearly all are getting out high-grade ore.

MINNESOTA

Mining operations on the iron-mining ranges are on larger scale at present than for some time, mainly on account of relief from the anxiety regarding coal supplies. Some mines are even establishing coal-reserves in preparation for winter stripping operations. Iron ore is moving forward to docks more freely and it is expected the month's shipments will show substantial increase. Twenty steamers are loading at Great Northern docks now and 29 are scheduled to arrive shortly. Eight boats are loading at Messabi docks and 11 are on the way there to load.

NEW MEXICO

Grant County.—The Silver King mine, a former producer, is being unwatered preparatory to development. T. C. McSherry of Silver City, backed by Eastern capital, is in charge of the work. If developments are favorable, a mill is planned and the mine will again be placed on a producing basis. During 1919 some 20-oz. silver ore was milled.

Hidalgo County.—The Great Eagle Fluorspar mine, under lease to Bell & Wright of Silver City, has put a second shift to work to fill contracts with Chicago firms calling for a large output of spar. The product is hauled by motor-trucks to Lordsburg for shipment.

UTAH

Grantsville.—Connection of the working adit of the 'L' Marie Mining Co. with the main working-shaft has been made, according to John V. Hong, Jr., general manager. The property of this company is in the Stansbury mountains, about 9 miles from here. Some time ago a shaft was sunk upon a promising outcrop of galena ore, to a depth of 130 ft. An adit was driven along a lime foot-wall and quartz hanging wall through well-mineralized territory. About 15 ft. from the portal a shoot of good ore was penetrated and a winze was sunk; 18 in. of shipping ore is now being followed.

YUKON

Dawson.—The yield of gold from the placer mines in the Yukon valley for 1920 is estimated to total \$4,485,000. There has been a considerable shrinkage in the output, owing to the dry season and the decrease in the purchasing power of gold. Six weeks more will wind up the season as the winter freeze will begin then.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

K. S. Twitchell has gone to New York.

E. P. Mathewson has been in Arizona recently.

S. S. Lang, of Houghton, Michigan, is at Magdalena, New Mexico.

L. D. Ricketts has gone from Santa Barbara to Warren, Arizona.

George Hyde, of Wellington, New Zealand, is in San Francisco.

T. H. Jenks has returned to Lake City, Colorado, from Los Angeles.

William Motherwell has moved from Melones, California, to Trail, B. C.

W. J. Kemnitzner, recently at Magdalena, New Mexico, is in San Francisco.

Edward H. Clark, president of the Homestake Mining Co., is at the Fairmont hotel.

T. H. Jenks passed through San Francisco on his way from Los Angeles to Colorado.

Charles Camsell has been appointed Deputy Minister of Mines in the Canadian government.

E. C. Marriage, manager of the assay-office at Pioche, Nevada, has returned from England.

C. H. Poirier, of New York, was in San Francisco on his way from Mexico to British Columbia.

Charles W. Adams, manager of the East Helena plant of the A. S. & R. Co., has been at Salt Lake City.

Robert N. Bell, State Mine Inspector of Idaho, has resigned, and will leave his position on January 1.

E. F. Gordon and **Oscar Hershey** have been examining vanadium properties near Good Springs, Nevada.

Dwight E. Woodbridge has returned to Duluth from a journey of exploration in the Hudson Bay region.

H. S. Gale has resigned from the U. S. Geological Survey to engage in private practice as a mining geologist.

George A. Laird has been appointed manager for the Guiana Development Co. and leaves for Guiana forthwith.

Joseph Chrisman, recently flotation man for the Leadville Mines Co., at Gerlach, Nevada, has moved to Bingham, Utah.

L. E. Grant, general manager for the Braden Copper Co., has returned to Rancagua, Chile, from Denver, where he has been since April.

Y. Fukihara, mining engineer for the Mitsubishi Mining Co., of Japan, has been in Utah visiting mines and metallurgical plants.

Harold Kingsmill, of New York, has been examining properties at Eureka, Nevada. He passed through Salt Lake City on his way home.

T. J. Renaux has been appointed mill superintendent for the Yellow Pine Mining Co., at Good Springs, Nevada, succeeding **M. P. Cloonan**.

W. J. Loring has resigned from the firm of Bewick, Moreing & Co., London. He is succeeded as partner in the firm by his son, **Edward A. Loring**.

E. T. McCarthy, of London, a director of the Mountain Copper Co., operating in Shasta county, California, is expected in San Francisco toward the end of September.

J. A. Burgess, who resigned recently as general manager for the United Eastern Mining Co., has opened an office as consulting engineer and geologist in the Mills building, San Francisco.

H. H. Claudet, manager of the Ottawa office of the General Engineering Co., was at Miami most of the summer and passed through San Francisco from Salt Lake City on his way home.

Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

August 30—Copper is quiet but firm. Lead is inactive and lower. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

That the Treasury Department can avail itself of the provisions of the Pittman Act to prevent a runaway movement in the silver market was admitted by Raymond T. Baker, Director of the Mint, in discussing the silver outlook. Director Baker is of the opinion that the recent decline in the silver market, due to a lull in buying from the Far East, is only temporary, and that the white metal will again advance.

Referring to the action of European traders and governments in melting silver coin and selling it as bullion, Mr. Baker said: "You must remember that in Germany and Austria their money was at such a discount in the world's money markets that it was practically useless. Their silver coin did have a value, of course, due to its silver content, and in view of the comparatively high price of silver it was natural that they should use their silver coin to purchase the things they needed. But at some time in the future both Germany and Austria must replace the silver coin that has been taken out of circulation, so there is a potential demand for silver from both those countries. The same may be said of Mexico."

Questioned as to the necessity for the passage of a law reducing the fineness of silver coins so as to protect them from sale as bullion in the event of another sharp rise in the price of silver, Mr. Baker intimated that the Treasury Department, through provisions of the Pittman Act, could control the situation.

"In the event of a rise in the price of silver to, say, \$1.42 or above, the subsidiary coins of the country would be in danger of being melted," Mr. Baker said. "The parity point of the subsidiary coins is, say, \$1.38 and of course the price would have to go above that to cover the cost of collecting and melting the coins and pay transportation charges. The price of silver would have to show a profit or there would be no incentive to melt coins."

"What the Treasury would do in event of such a rise I am not prepared to say, as its action would naturally be governed by conditions existing at the time, but a study of the Pittman Act will show what the Treasury could do. The Pittman Act authorizes the sale of silver bullion derived from melting silver dollars for the purpose of assisting foreign governments at war with enemies of the United States. That now is over. But the Act also authorizes the sale of silver bullion for the purpose of providing silver for subsidiary coinage and for commercial use as well as facilitating the settlement in silver of trade balances adverse to the United States. These provisions have not been changed by the termination of the War."

"Of the silver bullion sold under the Pittman Act we have re-purchased to date approximately 10,000,000 oz. at \$1 per ounce, and purchases are being made nearly every day. Should the price of silver go up to above \$1.42, what is to prevent the Treasury from re-selling this silver purchased at the market price? Suppose the price went to \$1.40 the Treasury could sell 25,000,000 or 50,000,000 oz., and if this amount should be absorbed and the price start to advance again, the Government could sell additional lots up to the full authority of the Pittman Act. And it might be recalled that the Treasury has a reserve of 50,000,000 silver dollars not availed of under the Pittman Act which could be sold to the Director of the Mint for subsidiary coinage at \$1 per ounce."

Foreign quotations on August 30 are as follows:

Sterling, dollars:	Cable	3.56%
	Demand	3.57%
Francs, cents:	Cable	7.12
	Demand	7.13
Lire, cents:	Demand	4.68
Marks, cents:		2.13

Eastern Metal Market

New York, August 25.

The markets are generally quiet and uninteresting with the price tendency, on the whole, easy.

The copper market is very quiet but firm with no change in prices or conditions.

Prices of tin are largely nominal and lower because of absence of demand and lower exchange, as well as a declining London market.

The lead market is manifesting an easing tendency with import metal the feature.

Buying of zinc is not heavy but prices are fairly even.

Antimony is lower.

IRON AND STEEL

To an increasing extent the steel trade is taking account of factors that bear on the future course of demand and of prices, says 'The Iron Age'. While some producers, long used to thinking in terms of a seller's market, talk of passing on the cost increment due to the 40% increase in most iron and steel freight-rates, others dwell on the final effect on their own market of the changes going on in other industries.

With an unwieldy accumulation of unfilled orders in most finished-material lines, such cancellations as have come on automobile and shipyard account have not been a marked factor. But there is the keenest interest throughout the market in any development bearing on the Steel Corporation's price policy for 1921 and railroad buying apparently is waiting for a cue.

The Chicago market, which particularly reflects the railroad situation, has been notably quiet apart from nuts and bolts and wire products. Here and there foundries in that district are curtailing operations and some of them will soon be in need of new orders. Railroad demand there has not yet developed in sufficient volume to offset the curtailment of automobile, tractor, and allied work. Gauged by cancellations and suspended shipments, a number of Detroit automobile plants are operating at about 50% capacity, while two of the largest are running full.

Production and shipments have improved in the leading steel-making centres, and Pittsburgh reports some reduction of mill stocks and nearly a complete clean-up of stored cars in railroad yards.

COPPER

Demand from domestic consumers is very light and the market is lifeless. It is rather surprising, but true nevertheless, that foreign demand is better than domestic but even this is relatively small and confined to orders that appear daily and come from various countries. Deliveries on contracts, however, are much better and as a result consumption is heavier. Ordinarily a buying movement of some proportion was due long before this but the railroad and labor troubles last spring and later delayed this. It is now expected in some quarters that buying on a large scale is likely in the next two or three weeks. Whether this and the increased freight-rates, effective this week, will result in an advance in price remains to be seen, but it is not unlikely. Leading producers of both Lake and electrolytic copper maintain their quotations at 19c., New York, for delivery to October, but are not especially interested beyond this delivery except in special cases.

TIN

The market is featureless and uninteresting and sales have been few and far between. A small business in future-shipment material was put through quietly in the last week, mostly to dealers. Consumers are still uninterested. The price of future shipment Monday was around 46.75c. with the quotation for spot Straits at 46.50c. the same day. Yes-

terday spot Straits was quoted at 45.50c., New York, which is 2.50c. below the price of a week ago, all these being largely nominal. The decline is due to the fall in exchange and to the lower London market. Yesterday spot Straits in London was £271 15s. per ton as compared with £288 three weeks ago. Arrivals thus far this month have been 3705 tons with 5395 tons reported afloat.

LEAD

The price situation in the New York lead market is such that most any estimate of the market is justifiable. Prompt and early-delivery metal has sold from 9 to 9.37½c. and import lead has changed hands at as low as 8.50c., New York, duty paid. The import supply seems to be the key to the situation here. It is authoritatively and conservatively estimated that at least 6000 to 8000 tons has been contracted for importation from England and some of this has arrived. The import cost of this varies according to the conditions in each case. Consumers realize the situation and are holding off. As a result demand has slackened and the market is quiet. The leading interest maintains its quotation at 8.75c., St. Louis, or 9c., New York, but is understood to be sold-up and to be offering nothing for early delivery.

ZINC

It is unusual to record the fact that zinc, sold or shipped to England, is being offered in this market for re-shipment, but this is the peculiar situation. Some of this metal has been sold at 8c., New York. Just what effect this is to have on the future of the market is not easy to say. Sooner or later, however, the British market must strengthen and relieve the pressure here. Therefore the effect of this import movement is small and the general market is strong with prime Western quoted and sold at 8.10c., St. Louis, or 8.45c., New York. Demand is light with galvanizers apparently well supplied for nearby needs. Production is low and stocks are not heavy, which is one element of strength in the market.

ANTIMONY

The market is quiet with wholesale lots for early delivery quoted at 7c., New York, duty paid. Jobbing lots are obtainable at ¼c. to ½c. higher.

ALUMINUM

The leading interest is quoting wholesale lots of 98 to 99% pure at 34.90c. per lb. f.o.b. producer's plant, while other sellers are asking 32 to 33c.

ORES

Tungsten: More inquiry is reported, developed largely by the low and attractive prices which are nominally \$5 to \$5.50 per unit for wolframite and \$6 to \$6.50 for scheelite. It is expected that a fair business will result in the near future.

Ferro-tungsten is quoted around 90c. per lb. of contained tungsten.

Molybdenum: No new business is recorded and quotations are nominal at 65 to 75c. per lb. of MoS₂ in regular concentrate.

Manganese: The market is lower with Indian ore offered at 65c. per unit, seaboard, but no business is yet reported. Former asking prices were 75c. per unit.

Manganese-Iron Alloys: Ferro-manganese has declined decidedly, due to offerings by some British producers at \$170, seaboard, for delivery into Jun 1912. American producers have met this figure which will make the delivered American price \$170 plus the freight from the seaboard to point of consumption. Some business has been done at the new price. The spiegeleisen market is strong but not active at \$80 to \$85, furnace, for any delivery. Supplies are not large because production has not been heavy this year.

*Of this sum, \$1,652,260 was paid by the individual companies prior to their amalgamation in 1914.

†This is a capital distribution, and reduces the par value of the stock from \$5 to \$4, corresponding to a reduction in total capitalization from \$3,000,000 to \$2,400,000.

Company Reports

BUTTE & SUPERIOR MINING CO.

Report for the quarter ended June 30, 1920.

Property: mine and mill at Butte, Montana.

Operating Officials: Charles Bocking, general manager; E. V. Daveler, general superintendent; Angus McLeod, mine superintendent; F. M. Jardine, mill superintendent.

Financial Statement: income, \$769,431; operating costs, \$940,433; net operating loss, \$147,006. Corresponding figures for previous quarter were \$1,750,770, \$1,123,514, and \$627,256, net profit instead of loss.

Dividends: none during 1920; total to date, \$16,940,258.

Production: ore mined during the quarter was 82,490 tons, at a mining cost of \$7 per ton, against 130,582 tons mined at a cost of \$5.52 per ton for previous quarter. There was milled 81,619 tons at cost of \$3.466 per ton, against 130,204 tons at cost of \$2.61 for previous quarter. The decrease in tonnage treated, with resultant increase in costs, was due to unsettled labor conditions during the entire quarter, which affected both mining and milling. A strike called April 19 resulted in a shut-down until May 5, when operations were resumed on a limited scale. Operations were being conducted on nearly a normal basis toward the end of the quarter.

DOMIE MINES CO.

Report for the year ended March 31, 1920.

Property: gold mines and mill in the Porcupine district, Ontario.

Operating Officials: C. D. Kaeding, general manager; H. P. Depencier, acting general manager; C. W. Dowsett, mill superintendent.

Financial Statement: earnings from sale of bullion, \$1,773,374. Cost of mining, \$315,873; milling, \$311,500, which with miscellaneous costs totaled \$930,762. Net operating, \$842,612. Miscellaneous income, \$109,372; profit for the year, \$951,984. After charging off depletion and depreciation, \$351,814 was credited to surplus.

Dividends: total to date, \$1,600,000.

Development: work was curtailed because of inability to obtain adequate supply of efficient miners. Broken ore in the mine is 251,352 tons. Work by diamond-drills from the 10th level disclosed ore at depths ranging to 216 ft., the holes being at approximately 45°. Ore-reserves are sufficient to promise production for at least three years.

Production: 270,080 tons of ore milled yielded bullion worth \$1,773,374, the average value being \$6.566 per ton. Cost of milling was \$1.153 per ton, and the extraction was 94.295% of the gold. A reverberatory furnace was built to smelt cyanide-precipitate, the increasing copper content of the product interfering with refining by the old method. The ore-handling underground has been simplified with resultant economy.

The Davis-Daly Copper Co. during the three months ended June 30, 1920, shows gross receipts of \$311,034; expenditures, \$325,035; loss, \$14,001. This compares with net profits of \$109,283 in the first quarter of this year and net of \$161,255 in three months ended December 31, 1919. The report says that cross-cutting on the 2700-ft. level should within a week or two reach the orebody on the downward extension from the 2500-ft. level. Tonnage hoisted for the quarter amounted to 17,414 tons, producing 2,197,936 lb. of copper and 91,238.5 oz. of silver. The average assay of ore shipped for the period was 7.07% copper and 5.88 oz. of silver to the ton.

NOTES	367
COLORADO SCHOOL OF MINES.....	369

Report of a committee of inquiry appointed by the American Association of University Professors. Charges are upheld. Dr. Alderson, the president of the School, is condemned for arbitrary and improper action. Mr. Parmelee, an ex-president, is defended for his stand against the trustees and striking students in 1917. The fault lies with the personnel of the board of trustees.

THE GREAT STEEL STRIKE.....	370
-----------------------------	-----

A critical review of the book by William Z. Foster. How the strike started and how it was organized. The campaign conducted by agitators in the Pittsburgh district. Large proportion of alien labor employed by the steel companies. American-born whites not favorable to the unions. Attitude of the negroes. The creation of a healthy public opinion and the need therefor of reliable information.

DISCUSSION

THE RECORD FOR CHEAP MINING

By Henry F. Collins.....	373
--------------------------	-----

Comparison of a case of exceedingly low costs at a Mexican mine with those at the Spanish mine, California.

TWO SUGGESTIONS ON A NATIONAL PROBLEM

By F. H. Mason	373
----------------------	-----

Criticism of the suggestion to use producer-gas for raising steam. Calls attention to the possibility of increasing the available automotive fuels by aid of by-products from the coke industry.

A METHOD OF BLASTING

By S. S. Lang	374
---------------------	-----

As usual the new method from abroad is found to be already in use in this country.

ENLARGING MAPS

By Samuel H. Dolbear.....	374
---------------------------	-----

Photographic enlargements render the topographic maps of the Geological Survey available as bases for mine reports.

ARTICLES

THE ORE DEPOSITS OF MEXICO—V

By S. J. Lewis.....	375
---------------------	-----

Ore deposits in igneous rocks with special reference to the mines of the Zacualpan district in the State of Mexico.

ROASTING AND CHLORIDIZING OF BOLIVIAN SILVER-TIN ORES

By M. G. F. Sohnlein.....	384
---------------------------	-----

Description of the metallurgical difficulties in obtaining a high extraction of the silver from these ores, with special comment on the results obtained with different types of roasting-furnaces. Special advantages of the Merton furnace for this work.

The Curve That's Straight

THE Linde engineer plots the quality of Linde Oxygen and across his paper extends an unwavering, straight line.

Day in and day out, week upon week, and through the year—the quality of Linde Oxygen must match this line.

If it fails by so little as a hair's breadth it never gets into a cylinder for shipment.

If specifying Linde Oxygen you assure constant uniformity—of Oxygen—and the resultant welds.

T. A. RICKARD, . . . Editor

HOW our bureaucracy has grown during the War and how little it has been decreased since the Armistice is shown by the fact that the Federal government has 760,110 civil employees today as against 420,752 in 1913.

MOVEMENTS of gold and silver bullion indicate the course of international trade. For example, during the first ten days of August our imports of gold amounted to \$8,071,045, of which \$6,664,234 came from the United Kingdom. During the same ten days we exported \$8,430,743, of which \$8,114,503 went to Asia. Exports of gold from the United States from January 1 to August 10 totaled \$225,719,396, or \$73,379,406 in excess of imports. The excess is a sign of increased importation from abroad, and the liquidation of some of our foreign loans. Silver imports during the same period, January to August, amounted to \$64,016,269, as against exports aggregating \$88,470,846.

SENATOR HARDING and Governor Cox have been quizzed by the American Association of Engineers on several matters of immediate interest to our profession. The Governor answered glibly that he gave "an unequivocal 'yes,'" whereas the Senator was characteristically equivocal. Yet the answer of one is worth about as much as that of the other, at least on the main query, which referred to the creation of a Federal Department of Public Works. It is more than probable that in the childish effort to saddle the opposing party with financial corruption neither has had time to consider such an important subject as the co-ordination of the engineering activities of the national administration.

A PIECE of quartz containing \$3000 worth of gold is on exhibit, says a San Francisco newspaper. It came from the Alcalde mine at Grass Valley, California. The quartz, it is reported, "runs in ribbon structure on a true-fissure vein, and is not merely a pocket." We hope it is not; we suspect that it is. The present writer took out \$3000 worth of gold in two hours in the Rathgeb mine near San Andreas, in Calaveras county, when a young man. He did not know much, but he suspected that it was a 'pocket'. Unfortunately such sweet ore does usually occur in small quantity and is so much more concentrated than the run-of-mine that the miner recognizes its sporadic character by calling it a 'pocket'. All of us love ribboned quartz and true-fissure veins, for are

they not the hall-mark of persistence? Nevertheless, it seems to be one of the ordinances of nature to regulate the size of orebodies more or less in inverse proportion to their richness. To expect specimen ore to exist in large or continuous masses is the triumph of hope over experience.

ONLY \$1,130,752 worth of silver was exported from this country to India during the fiscal year ended on June 30, as against \$214,481,099 in the preceding fiscal year. On the other hand exports of silver to China amounted to \$117,570,415 in the last fiscal year, as against \$24,571,791 the year before. It is evident therefore that the absorption of silver by China helped to redress the cessation of purchases from India. Adding the exports to the two countries, we find that the Orient took \$118,700,167 in the last fiscal year as against \$239,052,890 during the previous twelve months. It is no wonder, therefore, that the price of silver fell to 81 cents in May, a drop of 56 cents from the high point last November. Only the purchases under the Pittman Act prevented a further collapse, due, as shown above, to the inability of India to buy, owing to a sudden reverse in the flow of trade.

INTELLECTUAL dishonesty is the curse of world politics, as of similar activities nearer home. "The Brooklyn Eagle", an excellent newspaper, says that "France has declared herself to be in complete accord with the United States" in regard to Russian-Polish affairs. This is not true. France has hastened to recognize General Wrangel while he is yet recognizable, whereas our government has indicated clearly that it will not go to the support of any Russian faction, however much it may reprobate the so-called soviet regime. The United States and the United Kingdom agree in their decision to keep hands off Russia; and it is a pity that this policy was not followed sincerely long ago—either that, or a whole-hearted and united effort to smash the brigands who pose as communists. At the present time it seems to us a wise decision to let Lenin, Trotzky, and their crew stew in their own juice.

PONZI'S fraud has been fairly well exposed now. He collected ten million dollars from his dupes, simple-minded people who expected to make money quickly on a nebulous scheme based upon the vagaries of international exchange. As a matter of fact, this was a clean

fake, for he spent just six cents upon one international reply-coupon. All he did was to collect the money of his victims and pay back a part of it as dividends. When his 'depositors' and 'investors', as the poor things were called, became suspicious, owing to the much belated action of the proper authorities, he had to face a 'run', during which he returned \$5,900,000, besides the \$1,000,000 that he had doled out, as 'profit', before the crash came. He spent \$84,000 on a house for himself, besides \$15,000 in automobiles. He paid \$55,000 to a man who held him up, and an equal amount to lawyers. He gave a million dollars in commissions to his agents. At the accounting there remained \$1,073,432 in cash at the bank and \$658,377 in various stocks. There will be about \$1,500,000 for final distribution, which will represent about 50 cents on the dollar to the 'depositors' who failed to get out in time. He has been in jail twice already. His chief asset was impudence, plus the natural fact that the birth-rate among simpletons is large.

USUALLY 'house organs', that is, the publications issued by manufacturers to advertise themselves, are not interesting; they are all that 'literature' should not be; but some of them happen to get into the hands of a competent editor, and then they emerge from the mildew of catalogues into the fresh air of journalism. These preliminary remarks are prompted by the July issue of 'Through the Meshes', the propaganda of the W. S. Tyler Company, of Cleveland. In this little magazine we find the Constitution of the United States, which by itself would be impressive. In addition, we find an appreciation of the book 'Back to the Republic', by Harry F. Atwood, together with sundry timely remarks upon the critical period in which we are living. The essential difference between a republic and a democracy is emphasized, with a view to urging the need for a return to the ideals of the founders of this republic. The Government, both Federal and State, delegates too much power to boards and commissions. The Tyler company has a man that can put ideas through the screen of reason so that only those that have been ground fine by human thought shall pass forth into usefulness.

OBREGON has been elected President of the United States of Mexico. The election aroused but little popular interest and passed quietly, as is usual in Mexico, for the 'election' of a President is generally settled, by bullets rather than ballots, a short time before the electorate is called upon to confirm the practical result of an earlier and much more exciting contest. However, far be it from us to sneer at other people's ways of effecting the selection of a chief executive. In this case the result is satisfactory, because it places in authority a man of intelligence and character. Señor Alvaro Obregon—we do not call him 'General' because, we understand, he desires to be regarded as a civilian—is an 'Americanista', that is, he wishes to live on friendly terms with his neighbors to the north and hopes to have their financial assistance in reorganizing the industrial affairs of his own country. The new President of Mexico speaks the language of the

United States well; that in itself augurs for an understanding sympathy, for gentlemen can always be on a friendly footing if they but speak each other's language. We wish him well, and hope that his government will shortly receive recognition from ours. It will be a great blessing to have Mexico restored to order, for not only would we like our nationals to have the opportunity of resuming their mining operations under such laws as the Mexican government may impose fairly, but we are glad that the boggy of annexation has been quieted, at least for a time. Annexation would do more harm to the United States than to Mexico.

LAST week Dr. John C. Merriam, Professor of Paleontology in the University of California, was tendered sundry dinners and receptions by way of friendly farewell before his departure to Washington, where he will assume his new duties as head of the Carnegie Institution. His departure is a real loss to the University and to the State, but it is gratifying that a man of science so sincerely devoted to the cause of research should receive such well-merited promotion to a position of greater importance and wider usefulness. In these days not many of the devotees of science have the courage to stick to the pioneer paths of research when the muddy high-ways of commercialism promise them greater pecuniary reward. The application of geology to industry has gone so far as to suggest the possibility that unless there is more research there will be but little new science to apply. Many of the fundamental problems of geology are being solved, or are in course of solution, in the Pacific Coast region, notably in our own State of California. We can ill afford therefore to lose such men as Dr. Merriam. Incidentally, it is worthy of remark that paleontology, as a study of evidence on the development of life, floral and faunal, preserved in the rocks, was a principal factor in stimulating the central idea of evolution. It was to Lyell that Darwin owed the first hints of his own great concept, and it is to geology, particularly that part of it concerned with the sequence of rock formations, and of the vestigial record they contain in the form of fossils, that we owe the splendid imaginations of modern science.

THE Utah Public Utilities Commission, after a hearing lasting several days, has excepted freight-rates on intra-state shipments of ores, including coal, from the increase of 25% that it had authorized on other commodities in conformity with the action of the Interstate Commerce Commission. During the hearings, representatives of the mining companies showed that the increase of 20% granted by the Director-General of Railroads in 1918 had resulted in the closing of a number of mines that yielded ore of comparatively low grade; and figures were presented to indicate that a further increase at this time would be followed by the suspension of shipments from a large number of mines, with attendant hardship on various mining communities throughout the State. It was argued that the direct increase in the cost of shipping ore was only one of the burdens that the new rate-

schedule will place upon the operating companies. The transportation of fuel and fluxing material to the smelters and the shipment of bullion to Eastern refineries must be paid for in large measure by the producer, and increased freight-rates will likewise be reflected in the cost of mine supplies. The total average additional expense for the mining company, according to estimates presented, would amount to \$1.63 per ton. Mr. Walter Fitch, of the Chief Consolidated company at Eureka, testified that his company had shipped 20,000 tons of ore worth \$39.44 per ton during the second quarter of the year at a loss of \$0.316 per ton. Evidence given by other officials corroborated the statement of Mr. Fitch that an increase in rates would be a serious detriment to the industry. The railroad companies, when given an opportunity to present their side of the case, took the ground that the purpose of the proceedings was to arrange for increased revenue in an emergency, and should not be viewed in the light of a rate-making hearing. On this basis they asked that the horizontal increase be allowed and that particular questions as to rates be settled later. We surmise that the carriers recognize the importance of the mining industry to the welfare of the State; that they appreciate the position of the mining companies, and realize that many of them cannot operate if costs continue to advance. Whether properly or not, freight-rates have always been based to a large extent on 'what the traffic will bear' and apparently some of Utah's mining enterprises are already pretty well burdened. Since many of the smelters are in Utah, companies shipping ore from neighboring States, as, for instance, Pioche in Nevada, will doubtless feel badly treated at being compelled to abide by the ruling of the Federal Commission. Traffic officials admit that the refusal of the various State commissions to authorize parallel increases in intra-state rates may have serious consequences, and, if general, will defeat in a measure the purpose of the original award.

Colorado School of Mines

We have received a copy of the report on the Colorado School of Mines as submitted by a committee of inquiry appointed by the American Association of University Professors. Our readers are aware that the mining school at Golden has been the victim of recurrent scandals; they know that it has produced many mining engineers of high character and ability; they regret that the good repute of the School should be clouded repeatedly by ructions variously between the trustees, the faculty, the students, and successive presidents; and they will be interested in learning what report a competent committee of inquiry has made. We have read the complaints submitted by numerous professors and ex-presidents of the institution, together with the defence made by the trustees, and find ourselves in hearty agreement with the findings of the committee, which, in brief, are that Dr. Victor C. Alderson, who was president from 1903 to 1913, and was re-appointed in 1917, dismissed "strong teachers of professional rank and of long service . . . without charges, hearing, or adequate warn-

ing; that he lowered the standards of scholarship . . . by compelling members of the faculty to change [the] grades of students, especially of those who had influential relatives". Next, it is found that individual trustees "weakened the authority of the faculty by interfering in matters of discipline . . . and that President Parmelee was dismissed chiefly on account of the firm attitude he took in resisting interference on the part of the board [of trustees] with the faculty's responsibility for maintaining discipline and proper educational standards". The reply made by the trustees to "the sworn and detailed statements of former professors" is "uncandid and evasive"; in effect, it "admits the gravest of the charges as if they were of no serious importance". In concluding, the report says: "The conditions which were brought out in this investigation, unless remedied without delay, will prove most disastrous to the future of the School. To attract and to retain teachers of superior qualifications, an institution must protect them from administrative tyranny and from interference with their personal functions and responsibilities, and must maintain such standards as will permit men of character to enter and to remain in its service without loss of professional self-respect. This can only be accomplished if the authorities of the State of Colorado will appoint trustees who are competent to select and to support a president who has the proper educational ideals".

In short, what is needed is that the pressure of public opinion compel the Governor to select suitable trustees or that the law regulating the choice be so changed that it will be made intelligently and conscientiously by some other authority. We visited the School at the time of the students' strike in 1917 and realized the unfairness meted to Mr. H. C. Parmelee, as stated in our issue of June 16, 1917. The board of trustees at that time consisted of five, two of whom were graduates of the School and well fitted for their responsibility, but the majority of three consisted of a reporter on one of the Denver papers, a small banker living at Golden, the representative of the local boarding-houses and tradespeople, and a mining 'magnate', who failed to attend any of the meetings of the board until a crisis supervened, and then only added to the confusion by talking one way and acting another. The conditions that Mr. Parmelee had to face provoke satire. The reporter trustee, 'Cap.' Smith, actually authorized a citizen of Golden, entirely without official connection with the School, to tell the striking students to return to work and that "their suspended colleagues would be reinstated". In 1897, 1902, 1903, 1905, 1915, 1917, and in 1920, the School suffered from unfortunate publicity arising from domestic troubles. Sometimes it has been a president who has shown no decent consideration for the members of his faculty; sometimes it has been gross interference by the trustees with the authority of the faculty; and sometimes, in consequence, it was the students who proved mutinous. If the School is to survive, it must receive the best attention of the citizens of Colorado immediately. Of course, the slime of politics is over it all. The majority of the board of trustees are appointed by a politician, the Gov-

ernor. It may be right that the Governor should have some say in the administration of a State institution; he might be allowed to select the minority of two. We suggested in 1917 that some of the trustees be selected *ex officio*, for example, the president of the Colorado Scientific Society or the chairman of the local section of the American Institute of Mining Engineers. The alumni of the School elect two members, and they have been well chosen. The main thing is to divorce the School from local politics—and meretricious newspapers. We hope that the mining fraternity in Colorado will arouse itself to an exertion of whatever influence it may command in order to safeguard the School, which evidently is on the rocks. The Colorado School of Mines has done too well to be jettisoned; it deserves the best help of the mining profession in the hour of danger.

The Great Steel Strike

This is the title of a book by William Z. Foster on the steel strike of 1919. We read in the 'New Republic' that it was "a book of the first importance in American labor history" and we thought it well to read what one of the leaders of the strike had to say about it, so we ordered the book and read it carefully. Mr. Foster was the organizer of the strike and was responsible for the management of it as long as it lasted, that is, from September 22, 1918, to January 8, 1920. Officially he was secretary-treasurer of the committee that had charge of the fight. His book, of course, is an *ex parte* statement of the case, but it has value as giving us one side of the story; as a narrative it is not so "swift, vivid, and illuminating" as the reviewer in the 'New Republic' led us to expect, but it does throw light on a great industrial struggle and in parts is sufficiently candid to uncover the purpose and program of the left wing of the labor party. If Mr. Gary, on the other side, would give us his version of the affair we would be much nearer to an intelligent understanding of the causes and conditions governing the struggle, and any future struggle of the same kind, for the chief message of the Foster book is to threaten a recurrence of the industrial upheaval at an early date. The author says: "When the opportune time comes, which will be but shortly, the next big drive will be on"; and he promises that "the great steel strike of 1919 will seem only a preliminary skirmish when compared with the tremendous battles that are bound to come, unless the enslaved steel workers are set free". These quotations give a fair idea of the style and temper of the book.

Mr. Foster reviews the earlier strikes of 1892, 1901, and 1909, all of which failed. The effort to unionize the steel workers was resisted successfully by their employers. The European war afforded an opportunity to organize the workers. In 1918 Mr. Foster had been organizing unions in the packing-house industry of Chicago and was looking for an opportunity to use his energies in a new field. He suggested to his friends of the American Federation of Labor that "the organization of the vast armies of wage-earners employed in the steel industries is vitally necessary to the further spread of industrial democracy

in America". As he says, "the idea was to make a hurricane drive simultaneously in all the steel centres that would catch the workers' imagination and sweep them into the unions *en masse* despite all opposition, and thus put Mr. Gary and his associates into such a predicament that they would have to grant the just demands of the men". He counted upon taking advantage of the national necessity: "The war was on; the continued operation of the steel industry was imperative; a strike was therefore out of the question; the steel manufacturers would have been compelled to yield to their workers, either directly or through the instrumentality of the Government". He chuckles at the prospect of carrying out this plan, which was "the logical and practical one". It miscarried, because, although the unions under the American Federation of Labor approved the project, they failed to find the necessary funds. The conspiracy—for it was that, considering the fact that the nation was at war—succeeded only in unionizing some of the steel workers of the Chicago district. In October 1918 the U. S. Steel Corporation announced the adoption of the basic eight-hour day, with 50% extra pay for over-time. That was "a counter-stroke", says Mr. Foster, "which the national movement had been designed to forestall". Thereupon he and his friends moved to the Pittsburgh district and began their campaign of preparing for a strike, by enticing the steel workers into the unions that they organized in the various towns. They deserve credit for persistence, and even courage; for they had to face many obstacles, including "the chronic lack of funds, suppression of free speech and free assembly, raises of wages, multiplicity of races, mass picketing by bosses, wholesale discharge of union men, company unions, discouraging traditions of lost local strikes". Many pages are devoted to a description of the efforts made by local authorities to prevent public meetings; this was done variously by mayors, burgesses, and town councils. That such inhibitions were instigated by the steel companies is quite likely; that in some cases the methods adopted to prevent disorder were technically unlawful is more than probable. The townspeople did not want their quiet disturbed by the ructions of labor agitators, and, like the public generally, wished to be quit of the internecine struggle between the capitalist and the laborer. In many instances a meeting was permitted with the proviso that English only could be spoken. This touches an interesting phase of the struggle. The majority of the strikers consisted of the foreign-born. Omitting the office forces and bosses, "it is exceedingly doubtful if over 25% of the actual workers are American-born whites". So says Mr. Foster; the proportion is more nearly 40%. He continues: "How, then, can a general strike for steel workers be anything else than largely a strike of foreigners". That, of course, is one of its hideous features. The Americans did not favor a strike, partly because most of them belonged to the class of skilled labor, which was well paid. This fact Mr. Foster acknowledges in so many words: "But if the Americans and skilled workers generally proved indifferent union men in the steel campaign, the foreign unskilled workers covered themselves

with glory They proved themselves altogether worthy of the best American labor traditions". In order to recruit for the unions, it was necessary for the organizers to issue their circulars in four languages at least, usually in six, and the strike call itself was issued in seven languages. Another interesting fact is the aversion of the negro to unionism. "The indifference, verging often into open hostility, with which negroes generally regarded Organized Labor's activities, manifested itself strongly in the steel campaign. Those employed in the industry were extremely resistant to the trade-union program; those on the outside allowed themselves to be used freely as strike-breakers." Of the employees in the steel industry, 4.7% were negroes. They are mostly unskilled laborers, and are chiefly in the blast-furnace department. In the Homestead plants they constituted 12 to 14% of the working force. In that locality only eight out of 1737 negroes joined the union. "In the entire steel industry, the negroes, beyond compare, gave the movement less co-operation than any other element, skilled or unskilled, foreign or native." Worse yet: those on the outside were willing to be used as strike-breakers. Mr. Foster asserts that the steel companies recruited and shipped 30,000 to 40,000 negroes to the mills in order to break the unions. For this, he thinks the unions themselves are largely to blame, because "many of them sharply draw the color line", a discrimination he censures strongly, because it interferes with the plan of organizing all the workers irrespective of color, sex, race, or creed. In this particular, as in others, the steel workers showed much less solidarity than their employers. Although the steel companies independent of the so-called Trust, the U. S. Steel Corporation, had developed various systems of their own for collective bargaining, such as shop-committees and works-councils, in order to circumvent the unions, and although they had gone further than the Steel Corporation itself in correcting some of the abuses that provoked the strike, nevertheless, when the struggle with the labor agitators was once started, they supported Judge Gary to a man. The entire body of employers functioned as a unit; the solidarity of capital exceeded that of labor.

The strike was comparatively free from violence. Regular troops at Gary, militia at Indiana Harbor, and the State Constabulary in Pennsylvania were factors in maintaining order, but there can be no doubt that the workers were orderly chiefly because they were sober. Owing to war-time prohibition, the saloons were closed. Instead of buying drinks, the men bought food. Mr. Foster asserts that prohibition helped to prolong the strike, by conserving the financial resources of the men, many of whom formerly would have spent their savings in drink and then returned to work. Only 20 persons were killed during the strike, and some of these were the victims of criminal violence only indirectly related to the struggle. Mr. Foster, however, claims that "scores of scabs, because of their own or other incompetent workers' ineptness, were roasted, crushed to death, or torn to pieces in the dangerous steel-making processes during the strike". This statement, like others that he makes, may

be discounted. For example, the claim is made that the steel workers are under-paid and over-worked. It is true probably of some of them, as in other industries; many work over-time because the processes of steel-making require continuity of human effort in certain operations; the skilled men engaged in these special departments earn from \$13 to \$21 per shift. Other skilled labor earns \$7 to \$8 per shift. Common labor gets 45 to 50 cents per hour, or \$125 to \$140 per month. These were the figures published by the Steel Corporation at the beginning of the strike. Mr. Foster, criticizing the estimate of \$87,000,000 as the amount lost by the men in wages during the strike, says that it "bears the earmarks of Steel Trust origin, and is too low". Whereupon he bases his estimate of \$112,500,000 upon a rate of "\$5 per day per man". Again, in a letter to Mr. Gary, his committee claimed to speak for "the vast majority of the employees in this industry", whereas they had enrolled in their unions only 156,000, out of 500,000. He claims that 365,000 men went on strike, which, he asserts, was 90% effective. These statements are untrustworthy. Even his own story does not support them. The result of the strike renders them highly improbable. But there is one feature of his management that merits admiration, and that is the commissariat which he established with the funds given by other unions. He received \$418,141 for the purpose and spent \$348,509. At a cost of 9½ cents per week per striker he was able for four months to feed those who were destitute—a small minority only, apart from whom the steel workers were able to make "their long hard fight virtually upon their own resources". The cost of the strike to the men, in lost wages, was \$112,500,000. Mr. Foster's committee spent \$525,702. The cost to the steel companies was "several hundred millions of dollars", says Mr. Foster. To this must be added the loss to the railroads and to the many industries dependent upon either the consumption or the production of the steel companies. The total financial loss is incalculable. But, says Mr. Foster, it was well worth while. "The whole trade-union movement won a great moral victory." "The conclusion is bound to be optimistic and full of enthusiasm for the future." "The next movement will have to win by its own strength, rather than by the vagaries of a newspaper-created public opinion."

Here he places his finger inadvertently on the chief feature of the strike, namely, the stupidly helpless attitude of the public. It is obvious that these blind vendettas waged by obstinate and ignorant men are the negation of civilized life. The attempts of the Strike Committee to obtain a conference with Mr. Elbert H. Gary, the chairman of the finance committee of the U. S. Steel Corporation, and his replies to them exhibit a state of affairs that is intolerable. The matter is treated as if it concerned only these particular employers and their employees, numbering, all-told, only half a million people, whereas it affected vitally a commonwealth of a hundred million people. The ½% menaced the welfare of 99½%. We hold no brief for Mr. Gary; he may be an improvement upon Messrs. Vanderbilt and Baer as an exponent

of capitalism, but he too shows too small a realization of the obligations owed by him and his colleagues to the community in which they conduct their industrial operations and to the commonwealth under whose laws they are permitted to exploit a national resource. The only way to combat the unrestrained egoism and selfishness of the protagonists in such a struggle as the steel strike is to inform the public concerning the facts. Without reliable information the public is helpless; it truly is "damned", as Vanderbilt thought it ought to be. An ignorant and invertebrate public opinion is helpless. Mr. Foster announces that another and a bigger steel strike is assured within a year or two. Mr. Gary says, in effect, "Come on" or "Go to hell" to Mr. Foster. Is the public, that is, the nation as a whole, to wait supinely until the vendetta is resumed? Obviously the proper corrective is the publication of trustworthy data concerning the facts at issue, such as hours of labor, rates of pay, treatment of the men, housing conditions, and the other conditions that determine the reasonable welfare of the workers. The enormous profits made by the steel companies leave them no excuse for disregarding their obligations in such matters. If the information is to be reliable and convincing, it must be unbiased. The President should take the initiative in this matter, which is of national importance. President Wilson did well with his Industrial Conference; his successor can do even better by appointing a committee of inquiry that will command national confidence. The Presidential nominees should be asked their views on the subject.

One more feature of Mr. Foster's book remains to be discussed. At the close he outlines his philosophy frankly. The labor-unions are to be used as a means of establishing the dictatorship of the proletariat; that is Bolshevism; they must act in unison, so as to 'hold up' the entire country if necessary to obtain their demands. They have "surrounded themselves with a sort of camouflage or protective coloring, designed to disarm opposition . . . This is the function of such expressions as 'A fair day's pay for a fair day's work', 'The interests of Capital and Labor are identical', etc. . . . They are for foreign consumption. The fact that those who utter them may actually believe what they say does not change the situation a particle. Most movements are blind to their own goals anyway . . . The trade-unions will not *become* anti-capitalistic through the conversion of their members to a certain point of view or by the adoption of certain preambles; they *are* that by their make-up and methods." The italics are his. He believes that the trade-unions can be made so 'radical', that is, so much in accord with the views of men like himself, that there will be no need for a party of the Left, such as the I. W. W. He complains that the more militant members of the trade-unions have joined the I. W. W., thereby devitalizing the trade-unions, to which he looks for leadership in the industrial war he anticipates with so much confidence and cheerfulness. "In a word", he says, "the progressives must be won over from the idealistic and utopian to the evolutionary point of view . . . Indeed it must be

granted that insistence upon the real goal and tendency of trade-unionism will provoke the capitalistic class into greater opposition against the movement. But this will be treble offset by the added support which the unions will get from the large numbers of militants who now stand apart from them because of lack of understanding. The power of even a few such men, proceeding intelligently along practical lines, is one of the marvels of the labor movement." I quote at some length because it is well to understand the menace conveyed. His "evolutionary" seems to lack an 'r', for he speaks of recent events in England thus: "In England the turning point came ten years ago when she felt the great wave of sentiment for revolutionary unionism then sweeping the world. The question was whether this movement should realize its aims through the old unions or by starting new ones . . . Fortunately, Tom Mann and his colleagues, with a deeper knowledge of trade-unionism, were able to forestall this movement and to direct the strong stream of progressive thought and energy into the old unions. The result was magical. Within two years the great and successful strikes of the transport workers, railroaders, and miners had occurred, and the renaissance of the English labor movement was assured." Yes, and the whole network of English industry was paralyzed for a time by this magic touch, and would have been held by the throat if the public generally had not rallied to the support of the government. Let us hope that nothing so "magical" will happen in our country when Mr. Foster and his friends start their little game of terrorism. A combination of "great and successful strikes" among the railroad hands, the steel workers, and the coal miners, such as he pictures so jubilantly, will be a national calamity too tremendous to be contemplated with philosophic calm. There is one way to prevent it, and that is to create a healthy and intelligent public opinion on this industrial struggle between the corporations and their employees; such a public opinion will react upon both sides and hold them accountable. A public that is ignorant and supine will be trodden underfoot, as it deserves. The moral of Mr. Foster's book is that the Federal authority should order an investigation, ascertain the facts, and take the public into its confidence. By this is meant not an investigation such as was conducted under the auspices of the United States Senate during the strike, when a group of senators went into a room by themselves and summoned sundry witnesses to come before them, but a genuine inquiry conducted by competent men, say, three or five, in the mills and in the communities dependent upon them. The daily press cannot, we regret to say, fulfill this function. Too few owners of newspapers are sufficiently detached to treat the subject without bias. In the region directly affected by the strike the newspapers were controlled or subventioned by one side or the other. The matter is too serious to be left to the vagaries of journalism: it must be made the business of official inquiry. If the public is given reliable first-hand information, it will be competent to exert its proper influence. Without such information, it will be helpless.

DISCUSSION

The Record for Cheap Mining

The Editor:

Sir—I have only just noticed the very interesting article upon the Bunker Hill enterprise published in your issue of May 29, 1920, in which reference is made to the record in cheap gold mining and milling made by Mr. Bradley at the Spanish mine in Nevada county, California, as described in your issue of October 22, 1887.

Your readers might perhaps suppose that the record in question has remained unbeaten, and it may interest some of them to learn of a still lower record made at a Mexican mine and described in a note at the Richmond meeting of the A. I. M. E. in February 1901 and published in the Transactions, A. I. M. E., Vol. XXXI, pp. 445-449. The figures compare as follows:

	Spanish mine, California	Santa Fe mine, Mexico	
Number of tons	2796	10,274	
Operating costs, cents per ton:			
Mining: Wages	32.4	19.0	
Supplies	5.1	1.5	
	37.5	20.5	
Milling: Wages	12.3	9.0	
Supplies	10.7	8.6	
	23.0	17.6	
Yield of ore in gold.....	\$1.155	\$1.318	
Total cost, cents per ton.....	60.5	38.1	
Profit per ton	0.550	0.937	

The record made at this Mexican mine 20 years ago remains, I believe, unapproached to this day.

London, July 31.

HENRY F. COLLINS.

Two Suggestions on a National Problem

The Editor:

Sir—I have read with interest the letter by M. von Bernewitz on the gasoline and oil situation, and, though there can be no gainsaying the urgent need of discovering a way out of the present difficulty, I do not think it is to be found in the more extended use of producer-gas for raising steam and for use in internal-combustion engines.

Producer-gas is of inestimable value in many metallurgical processes, such as the open-hearth process for converting pig-iron into steel, where the use of a solid fuel is impracticable and where the rapid regulation of the atmosphere of the furnace from oxidizing to reducing, and the reverse, is of paramount importance. Likewise, where convenience is a main consideration, producer-gas has its uses, but as an economical means of burning coal for raising steam or for many metallurgical purposes in which coal-ash does not interfere with the reaction, producer-gas is not in the same class with pulverized coal as a fuel. Theoretically, the combustion of

carbon to carbon monoxide produces 2450 calories, the combustion of carbon monoxide to carbonic acid 5630 calories, and the combustion of carbon to carbonic acid 8080 calories. In the manufacture of producer-gas, therefore, that is in the conversion of the carbon of the coal to carbon monoxide, 30% of the heat value of the coal is lost. As a matter of fact, in practice a great deal more is lost, as is proved by the presence of 3 to 10% of CO₂ in producer-gas, but as combustion of coal even in the powdered state is rarely complete, we can afford to be magnanimous, put the one loss off against the other, and assume a loss of only 30% in comparison with the direct combustion of coal. That is bad enough, but it is not all. The nitrogen content of producer-gas ranges from 50 to 60%, with an average in excess of 55%; add to this 5% of CO₂ and we get 60% of inert gas in the mixture, which is a serious drawback when used as fuel for internal-combustion engines, in which the inert gases uselessly occupy valuable space in the combustion chamber. For raising steam, producer-gas has about one-third the calorific power of coal-gas.

The use of coal-gas as a fuel for stationary internal-combustion engines is, of course, far older than the use of gasoline; in fact, I believe I am right in stating that gasoline replaced coal-gas mainly on account of its greater convenience for use in automobiles. So the reversion to coal-gas for the propulsion of automobiles in England while there was a shortage of gasoline during the War was only to have been expected. I should like to explain to Mr. von Bernewitz, however, that the storage of the gas in "an unsightly bag atop of the machine", instead of in steel cylinders, as he suggests, was not due to innate stupidity on the part of the Briton, but to the fact that high-grade steel, such as is necessary for the safe storing of gases under pressure up to 2000 lb., which is common practice, was at that time in demand for far more important purposes.

I do not take such a pessimistic view of the automotive-fuel outlook as Mr. von Bernewitz appears to. At the present time there are more trained observers broadspread over the face of the earth searching for new oil-fields than ever before in the world's history, and to me it will be astonishing if this systematic search does not meet with reward. Lacking the discovery of new important oilfields, however, it is generally accepted, I believe, that far more oil still remains absorbed in the porous rocks of abandoned fields than has been taken from them, and attention now is being turned to the discovery of a method by which at least a considerable portion of this oil may be obtained. Then there are the vast

deposits of oil-shale that have been proved to exist on this continent and that are estimated to contain far more oil than has been recovered from oilfields in America in the past. It will take time and money, of course, to develop these sources and to build plants for the extraction of the oil. The work that is being started to recover gasoline, heavy oil, and bitumen from the tar-sand of the Athabaska valley, in Alberta, will be watched with interest.

In the meantime, I fully agree with Mr. von Bernewitz that the use of oil for raising steam and of gasoline for stationary engines where other forms of fuel is available should be discouraged.

Last year was the first year in the history of the United States that the amount of coal coked in by-product ovens exceeded that coked in beehive ovens. As much as 46% of the coke produced is still made in beehive ovens. Each ton of coal carbonized is capable of yielding about two gallons of liquid that not only can be used by itself as an automotive fuel but that has the property of making alcohol miscible with gasoline and providing a fuel composed of three substances that may be used in existing types of engines. Straight alcohol, of course, requires a specially designed engine. It behooves the producers of coke, therefore, to see that the by-products evolved during the destructive distillation of coal are saved. The automotive-fuel situation admittedly calls for serious thought and active research, but not, I think, for anything approaching panic.

F. H. MASON.

A Method of Blasting

The Editor:

Sir—On page 276 of your issue of August 21 you have a paragraph stating: "A method of blasting a heading, possessing a new feature, is reported from the Nordhausen mining district in Germany. Instead of two or three inclined shot-holes in the centre to un-key the face of the work, the holes are bored parallel with the axis of the drift, locally known as 'canon-shots'. These are arranged and fired to make a hole of no great diameter in the centre of the face by crushing the rock. Then a ring of shot-holes is bored around this central opening and fired. This removes a considerable mass of rock, thereby greatly enlarging the central opening. Another ring of holes, more widely spaced, clears the face. The novelty consists in the closely situated central crushing holes. Being so near together, it is not necessary to have a primer and fuse in each. The concussion of one shot is sufficient to fire the rest."

This is not a new method; it has been used in this country for a number of years, especially in raises, for which it is best adapted. The cut as used in this country is called the 'hunt' or 'barrel' cut. It consists in drilling three or four holes as near as possible together, in the centre and parallel to the axis of the raise. Instead of loading all the cut-holes, as in the German method, only one or two of the holes are loaded. The blasting of these

holes breaks the walls of the others, leaving an opening of barrel shape, from which the cut receives its name. This is a good cut in raising, because the barrel frees itself of loose rock and allows considerable space for the other holes to break to.

In most mines the complete round is drilled, because, otherwise, the ground would be so shaken by drawing the cut-holes that in drilling the other holes afterward there would be considerable delay with fitcher holes.

The article states that "the novelty consists in the clearly situated central crushing holes. Being so near together it is not necessary to have a fuse or cap in each. The concussion of one shot is sufficient to fire the rest." In recent years, with the new light drills it is possible in most drifts and cross-cuts to swing the machine so that two or three cut-holes will meet, and while they all have primers and fuse, in most cases one primer and fuse would be sufficient to blast all of them.

Houghton, Michigan, August 24.

S. S. LANG.

Enlarging Maps

The Editor:

Sir—I have had occasion to use, in the preparation of mine reports, a topographical map in cases where the cost of an actual survey is not justified. If the district is included in any of the published topographic surveys of the U. S. Geological Survey, an excellent substitute may be had by a photographic enlargement of the Geological Survey map. The latter is usually drawn to a very small scale and the location of workings, buildings, etc., cannot be accurately indicated on them.

Enlargements must be made accurately, preferably 5, 10, or 20 times, so that the scale may be preserved in simple ratios. Thus if the original scale is $\frac{1}{125,000}$, an enlargement of 10 diameters will increase the scale to $\frac{1}{12,500}$.

Portals, buildings, and other objects may be tied into some point shown on the Geological Survey map. If the enlargement is 20 diameters it will be necessary to make a tracing from the photograph, as the original lines have also been enlarged and become too wide and ungainly. Blue or black-line prints should then be made.

I have found maps prepared in this way to be very satisfactory and sufficiently accurate for ordinary requirements. It should be borne in mind, however, that if any inaccuracies exist in the original map, they will be proportionately increased. Too much dependence should not be placed on section-lines shown in these photographic maps. In some of the topographical maps, the notes of original section-line surveys appear to have been disregarded, and nothing but an actual survey, using the notes on file in the U. S. Land Office, will suffice. This is especially true in mountain areas, where the course of the section-lines appear to have been determined by the convenience of travel for the transit-man rather than by his instrument.

San Francisco, August 10.

The Ore Deposits of Mexico—V

Ore Deposits in Igneous Rocks

By S. J. LEWIS

INTRODUCTORY. Ore deposition results from chemical reactions. At bottom, the differences between those in limestone and those in igneous rocks reside in the fact that in the former the igneous structure, whatever its size or place, that we associate with the orebodies, is restricted; it serves as the conduit or passage from the buried magmatic mass to the limestone rocks; so that we can readily refer the ensuing precipitation of mineral to the action of the alkaline wall-rock on the sulphide solutions. In igneous rocks we are not dealing with a limited intrusion that serves merely to connect the limestone with the igneous reservoir, but with the reservoir itself: that is, with a more or less homogeneous mass of practically unlimited extent, out of which the magmatic solutions proceed, and in which the conditions of precipitation must usually be determined by other elements than the comparatively simple one of a contact with rock of different composition.

Mechanical forces, by fracturing the rocks, make openings that serve as Nature's receptacles for the circulating ground-water, in which reactions can take place as they do in any other container. Later similar forces introduce factors favorable to enrichment, like dikes or cross-faults, which frequently are of great importance in determining the distribution of ore; but aside from these ground movements, the whole process is chemical in its nature, strictly comparable to the work done in the laboratory, and differing from it principally in its enormous complexity and scale, and in the fact that we do not control it. In our experimental work we study the effect of a single reaction by excluding all others; in the work of ore deposition a multitude of reactions must go on together, with an intricacy of interchange that we cannot wholly grasp. Nevertheless, the only reasonable concept of the origin of orebodies in igneous rocks is based on the recognition of the whole process as being a series of chemical precipitations carried out on a vast scale in Nature's own receptacles.

A thick structure of volcanic rock presents special interest, because the mass may be regarded as of fairly uniform composition, possessing much heat which must be slowly dissipated, and exposed to surficial oxidation only after its surface has cooled and hardened. Fracturing in such a structure will in a general way occur in two periods: the first comes simultaneously with the crystallization of the rock-minerals, that is, it will be due to the contraction of the structure in volume; the second period will be marked by later fracturing across these cracks, caused by later intrusions or by regional movements, which will affect the mass more or less like

forces exerted on rigid bodies. In such formations, therefore, we should find the channels of deposition irregular and branching, with sudden changes of dip and variations in strike, much like the cracks that occur in badly-annealed glass and having a similar origin; while the later fractures become local influences retarding or accelerating circulation and thus making for enrichment of the ore.

The two stages of mineralization in igneous rocks are therefore recognizable as the entrance, into the newly-formed fractures, of two different kinds of solutions: first, a direct filling with silica in various stages of gelatinization, carrying dissolved metallic minerals, all coming direct from the magma and usually hot; and, second, the entrance into the same channels of the thinner, colder solutions left after the excess silica has worked its way out. It will be obvious that differences in chemical equilibrium between these two classes of solutions will cause precipitation.

It is a matter of common knowledge that gold usually occurs in nature in quartz veins, either free from other metals except silver, or else closely associated with iron pyrite. It is also well known that silica, dissolved in acid, will under suitable conditions set to a jelly, just as ordinary gelatin does. If to such a preparation be added a solution of gold chloride, the latter will diffuse itself thoroughly within the solidified silica.¹⁷ If now a watery solution of some precipitant be poured on top of the gelatin in the test-tube, two things will happen if conditions of molecular pressure are right, which throw a great light on the formation of such orebodies as we are discussing: first, the gold will be precipitated in crystals or aggregates, in the body of the jelly, and in larger bodies or crystals than are obtainable by other means; second, the precipitation will usually occur not all in one mass, but rather in aggregates scattered through the gelatine, and frequently in a series of bands of mineral separated by clear spaces. In the original Liesegang reaction, discovered in 1896, the bands of mineral were circular and concentric, alternating with light bands as in the later experimental work. The appearance produced is similar to that of a fine piece of red agate, which, it is believed, gets its banded appearance by the precipitation of iron in the way described.

The important factor in these reactions, and one bearing directly on the application of the principle to the formation of orebodies in nature, is the degree of molecular concentration of the mineral in silicious solution, com-

¹⁷Hatschek & Simon, 'Gels in Relation to Ore Deposition', Trans. I. M. M., XXI, 1912, p. 452.

pared with the degree of molecular concentration of the mineral in watery solution. The bringing together of two such media sets up circulation of the molecules from one medium to another: that is, osmotic pressure is induced in one direction or the other, depending on which is the more highly concentrated. If the concentration is greater in the watery solution, which is poured on top of the gelatine, the former will flow into the jelly and the gold will precipitate inside of the latter; if the concentration in the jelly is greater, then the pressure will be the other way and precipitation will occur in the water, at or close to the contact surface of the two media. The most important point is that the reactions can take place within the gelatine, notwithstanding the latter is either semi-solid or quite solid; and it has been shown that this is the case even if blotting-paper be used instead of gelatine, the reactions taking place just the same, only more slowly. It will be clear that the principle should hold true for minerals dissolved in solutions held in the solid igneous rock, given the difference in time, pressure, and temperature. I have seen a copper deposit in andesite in the State of Jalisco, near Colima, in which an area of several hundred square metres, and several metres thick, was well mineralized with flakes and crystals of pure metallic copper, which could hardly have been deposited in any way except from copper solutions moving through the solid rock and reacting with some other solution. The crystals of galena scattered through the limestone of the Mitra mountain, in Monterrey, above the dolomite horizon, may well have had a similar origin. In both cases, we must view the rock as a container of silicious copper or lead solutions, to which at a certain time a reducing solution of proper molecular strength found its way, just as it would into gelatine, and that in the same way it brought down the crystals or aggregates of mineral. In a similar way, the experiments with the solutions in test-tubes are paralleled by the filling up of fracture-cavities in igneous rock with gelatinous silica, which is subsequently acted on by reducing solutions. The delicate balance of molecular concentrations necessary for deposition to take place will evidently not often occur, making it clear why orebodies exist only here and there, and sometimes not at all, in otherwise fine-looking veins; the irregular shapes of the aggregates precipitated are paralleled by the irregular distribution of values in ore-shoots; and, finally, the alternation of bands of mineral with clear spaces in the test-tubes is paralleled by the occurrence of ore in lenses irregularly spaced one below the other in quartz veins, the lenses of mineral being separated by barren quartz. We thus reach the concept of a quartz vein carrying gold, silver, or other metals, as being a solid solution of silica in a rock-channel, with precipitated crystals or aggregates of the metals, held within the quartz just where they were precipitated.

A molten mass of igneous rock, existing under high pressure and temperature in an area of volcanic activity, before being expelled to the surface, must be a semi-fluid mass, in which the rock-minerals are carried in

silicious and aqueous solution, and carrying also much excess silica and great quantities of magmatic water. These mineral solutions may be conceived to circulate freely in any direction throughout the mass, depending on molecular pressure. With the extrusion of the magma during an eruption, as in the pouring out of a lava sheet, the reduction in temperature and pressure would induce the immediate beginning of crystallization of the rock-minerals, simultaneously with a contraction of the mass and the formation of fractures or openings, the first of the three elements required for our reactions. The excess silica produced from the rock-crystallization could therefore find its way quickly into the openings, there to gelatinize gradually as it has been shown to do in certain mines, finally hardening to quartz. As this excess silica carries in solution many of the metallic minerals derived from the magma, we shall then have the fractures acting as receptacles for the gelatinous solutions of the metals, furnishing the second element we require. We would then lack only the addition of a watery precipitant to complete the requirements, and make possible the formation of orebodies.

Such a precipitant is furnished, if the conditions of pressure are right, by the magmatic waters resulting from the differentiation of the rock-minerals from the magma. Such thinner, later solutions of the metals, introducing a change of chemical conditions, can work into the gelatinized or solid silica in the vein-channels, with ensuing reactions. The precipitated metallic sulphides would then be found either as isolated perfect crystals in the solid quartz, or as aggregates or masses of crystals, sometimes of two or three metals, or grouped in horizontal banded structure or in concentric bands; or in lenses formed by combinations of all these forms, deposited in the quartz-vein in an irregular mass, with similar ones occurring under it and the bodies separated from each other by spaces of barren quartz. The existence in Mexican mines of types illustrating these reactions is familiar to all of us, especially in 'rosario' silver mines and in the concentric banding of many silver ores.

ALACRAN. These phenomena are beautifully illustrated in the well-known mine of this name in the Zacualpan district of the State of Mexico. Where the vein is narrow, between ore-shoots, banded structure is common. In the ore-shoots, concentric banding, in thin laminations parallel to the vein-walls, with the lines of deposition perpendicular to the latter, are common. Fig. 16a shows a piece taken from the bottom of the mine, 100 m. below the level of the Rio Alacran. The light bands are barren quartz, the dark ones are sulphides of silver and iron, with a trace of copper. The close resemblance to the concentric rings of the Liesegang experiment speaks for itself.

Five known chimneys occur in the mine, irregularly spaced over about 800 m. of strike, like beads on a string (Fig. 16b). This arrangement is usually assigned to cross-veins cutting across the lode; but I have never seen the cross-veins, and if they really exist they must

Fig. 16.

Alacran Mine, Zacualpan.

FIG. 16

be small and insignificant. The four parallel veins in the Alacran lode are well known and usually well defined. Only one of them carries the very rich ore that has given reputation to the mine. I believe that the importance of vein-intersections in this mine, and in general in the district, has been exaggerated. In the Alacran, they seem to have little, if anything, to do with the mineralization.

I have had the privilege of examining the latest of these bonanza orebodies,¹⁸ which is at the bottom of the mine, and of studying the mine-plans. The remarkable alternation of lenses of silver-gold ore with spaces of barren quartz and wall-rock can at present be fully explained only as an example in nature of the silica-jelly reaction that we have been discussing. Throughout the whole ore-shoot, and it is said, in the old ones also, the ore occurs in nearly horizontal bodies 30 to 40 m. long, going down 20 to 25 m., and separated from each other by the same intervals of barren ground; one lens lies under the other, all having a slight pitch to the north and downward as in the sketch (Fig. 16c). Four such lenses have been worked in the present ore-shoot. In cross-section, the condition presented is like a string of short sausages (*d*). It has been stated locally that the alternate swelling and pinching of the orebody was due to the influence of layers of rock of different kinds, in the walls; but, as the formation is wholly in the Zacualpan andesite or greenstone, with totally insignificant inclusions of shale, such a hypothesis cannot be taken seriously.

Where the ore fails, the vein is usually only a few centimetres wide, and is at times hardly distinguishable, there being no walls and no openings. At enriched places, lenses of silver sulphides are found, 30 to 70 cm. wide, the ores carrying from 20 to 60 kg. silver per metric ton. The wall-rock for a short distance is also impregnated to the point of making good mill-ore. The unenriched spaces between the orebodies usually assay 400 to 500 gm. silver. All the high-grade ores carry gold, with a characteristic accompaniment of iron and copper sulphides.

There are many cases where such a series of lenses may be due to movement of the vein-walls on each other. Curved parts are thus brought together to form alternate swells or pinches. At Alacran there has been no discoverable movement of the walls; there is no gouge, no breccia, particularly no vein; the mineralization consisting merely of a streak of banded quartz, at times almost invisible. The vein is really a hardly distinguishable channel of mineralization, out of which silver minerals have diffused into the wall-rock and replaced it. The silver minerals in the silicious solutions filling this fracture must have been in a state of quite extraordinary concentration. Precipitated by some change of chemical condition, they came down in the silica of the channel and especially in the wall-rock adjacent to it, in a series of bands one below the other as in a gigantic beaker.

On this theory we can easily understand the irregular and infrequent occurrence of ore-shoots in quartz veins. Cases where enrichment occurs at all swells and impoverishment at all pinches are comparatively simple; but they are in the minority. In most cases the pay-ore pinches out while the vein remains the same size; or the replacement of wall-rock to make ore occurs as a lens in unreplaced material.

Strictly speaking, we should regard secondary sulphide enrichment as a special case of the same process. We then have an existing orebody acting as a solid silicious solution of metallic sulphides, attacked by watery solutions of the same or other metals, the ensuing reactions causing precipitation in the solid quartz vein and consequent enrichment.

A rough classification will be useful to us in making even a brief study of igneous deposits in Mexico exemplifying these principles; the simplest may perhaps be based on the nature of the igneous mass in which the ore deposits occur. We may thus divide them into two classes:

1. In igneous masses intruding older formations.
2. In surface flows of varying composition.

The first class forms a link between the deposits in limestones, already studied, and those purely igneous masses; it will therefore be convenient to take it first. The second class is by far the largest and most important, for the flows are found in the great silver-producing mines of Mexico.

Class 1. In igneous masses intruding older formations.

THE ZACUALPAN DISTRICT. Here, in the southern part of the State of Mexico and close to the Guerrero line, are excellent illustrations of this class. The mines were alluded to above in discussing the Sultepec continuation of the El Oro shales.

The ore deposits of Zacualpan are in a green andesite like that of El Oro. In thin sections the rock is seen to be profusely pitted with amygdules, in which the processes of oxidation have deposited beautiful crystals of secondary hydro-silicates. The ferro-magnesian mineral is generally hornblende and is not abundant. The rock is fresh, generally speaking, but shows much strain in the vicinity of the veins, and flow-lines can frequently be distinguished. Secondary quartz and calcite are plentiful in the minute veinlets of the rock. A schistose appearance has been induced in the neighborhood of veins owing to the heavy pressure to which the mass has been subjected.

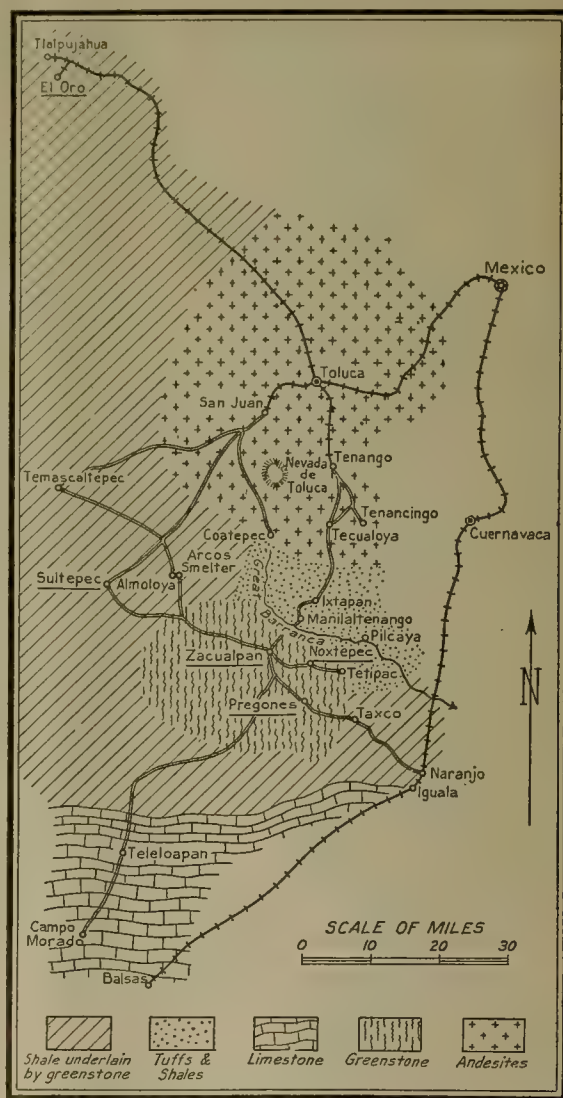

This andesite is the only eruptive rock in the district and is the principal member of the formation. Black and gray shale, similar to that of El Oro, occurs in scattered bodies as the subordinate member. This shale, coming down from Queretaro and Guanajuato to El Oro, thence to Sultepec and into Guerrero, has been pierced by one or more laccoliths of the andesite, presumably in Miocene time, from a centre at or near the Toluca volcano (see map). The igneous masses, working their way between the strata, pushed them up and tore them away

¹⁸Through the courtesy of Don Pedro Melendez, Director, Neg. Minera Alacran y Anexas.

until the intrusion was solidified. The domed part of the shale was also the thinnest, and with the breaking due to the uplift became easily degraded by atmospheric agencies. This wearing away has exposed the andesite throughout the district, with the shale on its flanks and with small inclusions scattered all through it, some visible on the highest hills of the district. A cross-cut of the country from Sultepec to Zacualpan* (Fig. 13) shows the shale in place at Sultepec, though much disturbed in dip and composition, and the greenstone underlying it in the form of a sill, much as at El Oro. Between the two towns are a few small isolated masses of limestone of the late Cretaceous. Continuing south toward Zacualpan, the greenstone mass rises higher and the shale thins out, until we come to the Zacualpan district proper, where the greenstone forms the whole surface, the shale appearing only as scattering inclusions, or 'islands', varying in size from a few cubic metres to many thousands. These evidently were torn loose from their original bedding by the swelling intrusion, floated on the molten mass, and solidified where chance found them when cooling began.

Vein formation, resulting from cooling and settling of the laccolith, has been extremely complex in this district. The fractures have followed the general laws we have discussed; but instead of cracking through a homogeneous mass, the movements have encountered the shale inclusions alluded to, and have gone right through them; and the deflection of path, modification of channel, or change in character of vein-filling, have all been matters of vital importance to the miner. Adapting themselves to the difference in brittleness of the two rocks, the fractures have been strong and well defined as long as they continued in the andesite; but wherever they have encountered shale, the strata have yielded to the movement, partly returning to their old position, and the channel has consequently been made much smaller. For the same reason, such places show temporary changes of dip in the vein. The mineralization therefore is nearly everywhere narrower in the shale than in the andesite, besides being usually of a different character. The general rule of the district has been that as long as the vein stayed in andesite good ore could be expected, but that if shale was encountered in the course of stoping on good ore, the assay-value would drop immediately and coarse zinc and lead, with but little silver, would be dominant in the mineralization. A good illustration of this condition was noted a few years ago in the Cuchara mine close to the town, one of the minor properties of the district. It had yielded small orebodies from Spanish times and had been worked down to the level of the Alacran river, which drains this part of the country. At this level the mine was apparently bottomed; a drainage-adit driven 600 metres from the surface to cut all the veins, with about 200 metres of exploration on them, showed no ore of value. The mine was practically abandoned. Careful study of the ground showed a horizontal inclusion of shale, about four metres thick, outcropping in the arroyo at the level of the adit, with the solid andesite

beneath it stretching away for several kilometres down the arroyo. Investigation showed that the long and vitally important adit had been driven for its whole length in this accidental shale formation, varying in thickness from the four metres seen at the surface to about 18 m. at the thickest known point in the mine. High-grade ore, which had been followed down to this

GEOLOGIC MAP OF ZACUALPAN DISTRICT

level in a satisfactory width, pinched to a few centimetres of black-jack and coarse galena, the usually persistent antimonial silver disappearing entirely. Twelve metres of exploration downward had failed to show improvement; evidently it was necessary to pass through the shale and get into the andesite again. The winze therefore was cleaned out and deepened, the shale left behind, and with a total of 20 metres of new sinking, the upper edge of a new orebody was cut, carrying rich silver minerals, which persisted down to about 80 m. below the level of the arroyo.

*See 'M. & S. P.' of June 26, page 935.

A similar occurrence was noted in Chontalpan on the fourth level north several years ago. Excellent ore dropped to 200 grammes per ton when the drift entered the shale, and returned to a kilogramme when the shale was passed. On the other hand, the most valuable orebody found in the Chontalpan mine in modern times occurred below the fourth level at a point where there is a great deal of shale in the foot-wall.

The Zacualpan ores are silicious, with considerable calcite in the gangue of some of the veins. The silver appears both as proustite and pyrargyrite, but principally as antimonial ruby silver. At Chontalpan the ruby usually occurred massive, smeared over the surface of the ore, especially in conjunction with fine-grained lead. At other mines near-by, the Carmelita for example, the ruby occurs in fine crystals and needles, quite transparent and standing on end within small cavities. Argentite is common and is disseminated through the ore. Good crystals are found occasionally, both free in cavities and embedded in the gangue. Some fine stephanite crystals have been found also, especially at Chontalpan. Native silver occurs commonly in the form of wire and flakes, usually the former, in small cavities in the high-grade ores.

Gold is not an important mineral in this district. In the strictly-silver mines, like Chontalpan and all those close to the town, the gold rarely exceeds a gramme per 'kilo' of silver. In the mines verging toward the western edge of the district, like Alacran and Carboncillo, a high gold content is noted, usually from an ounce to two or three per ton.

Zinc occurs in two forms. The coarse-grained black-jack, generally associated with coarse galena, seems to be the primary mineral. The light-brown zinc *acopalado* that is invariably associated with silver minerals, seems to be of later occurrence. It is found in some of the mines in fine branching leaf-like or tree-like crystals, grown into the calcitic gangue, outward from secondary fractures in the vein-filling. In other mines it occurs as fairly large crystals scattered through the rock. Lead occurs in the same way: coarse large galena crystals with little or no silver; and fine-grained, steely lead, the *acerado* of the miner, with pronounced silver enrichment. Wherever pyrite is found in coarse crystals it also is barren of silver; in most of the mines of the district the iron sulphide shows poor silver mineralization at best. There is, however, a class of pyrite, fine-grained and frequently associated with a little copper, that is rich in silver. Marcasite occurs sparingly, associated with silver minerals, in beautiful thin plates in cavities.

The veins usually have a well-defined hanging-wall stringer and frequently a similar stringer on the foot-wall, with the rock between unreplaced, or shattered and partly replaced by stringers of ore, or completely replaced by sulphides of lead, zinc, and iron, with silver. The average width of the veins is from 30 cm. to a little less than a metre. Calcite occurs usually as spar; quartz as massive silica with occasional fine crystals in open spaces. A fibrous amphibole occurred in the Cuchara mine in depth, associated with the pay-ore, loose in cav-

ities. Silver-bearing ores of bismuth and antimony also occur in small quantities.

Although the veins are narrow, the ore is so rich in silver at points of enrichment that mining is profitable; and the strong walls, without dangerous gouge or much water, make the camp attractive for operators with little capital. Few of the mines have had the advantage of modern metallurgical methods or equipment, and there has been little systematic development.

The controlling factor in the deposition of ore in this district is commonly supposed to be the intersection of veins or their coming together in some way. As I look back over many years of experience in this and other districts, it is surprising to see how few mines there are where the orebodies were found at the intersections of the veins, and it may be worth while to go over a number of examples to see what truth there is in this popular generalization.

In the Cuchara mine, the fracture system consists of two principal veins: the high-grade vein, running north and south, and the low-grade lead vein, running east and west (Fig. 17). The second is a later vein that cuts off the principal vein in the southern part of the workings, displacing the faulted ground so far as to take it out of the property. The northern part of the ground, about 120 m. away, is also cut off by a late vein parallel with the lead vein. The two fault-veins dip toward each other, so that the short undisturbed block between the two fault-planes, like an inverted pyramid, is the productive formation, by which is limited the life of the mine. If it were true that orebodies occur at the intersections, we should get an orebody at each end of the undisturbed block; as a matter of fact, the valuable ore has always been found at some little distance from the area of disturbance.

In this example the angles of vein intersections are high, from 45° to 75°. Our next example is one showing acute angles, from 15° to 25°, in the Carboncillo mine at the southern edge of the district. The important orebody taken out here in recent years has been mentioned already; it occurred on one of the four veins of the fracture system, not immediately at the intersection, but at 30 or 40 m. from the junction of the veins. The rich mass was about 30 m. long by 25 m. high. Mineralization at the intersection itself was meagre.

In the old San Miguel Tlaxpampa mine, at the edge of Zacualpan, four veins come together at an acute angle. Generally speaking, the orebodies have not formed at the intersection, but rather at short distances therefrom. Where the veins diverge like a fan toward the north, it is interesting to note the parallelism of ore occurrence on all of them (Fig. 19). The lenses of silver ore are found at 30 to 100 m. north of the general intersection, on all of the veins so far as known.

In the Chontalpan mine, at the extreme southern edge of the district, the most remarkable intersection comes at the extreme south end of the principal level. Here three veins come together to form the main vein; the three branches have been followed south for long distances

without showing any ore of great value. The intersection itself shows nothing at all in the way of ore; real mineralization begins at about 30 m. north of the junction and goes on without apparent relation to the intersection. See Fig. 20.

These are all cases where mineralization is known to persist as pay-ore. The case of Alacran has been cited already. In other cases, like the Bella Vista on the Acebedotla river, there is a fine intersection of two veins, but no ore; the little surface pockets formed near the

therefore, in the last analysis are merely the evidence of later fracturing, or the channels by means of which the later precipitants have been brought into the reaction. They are of the highest importance; but they do not necessarily signify ore deposition, and the idea that ore generally occurs at such intersections is not well supported by the facts. Numerous intersections simply mean that the ground has been well loosened, probably at two or more different periods, and they are therefore a favorable sign, but nothing more.

FIG. 17. SYSTEM OF VEINS IN THE CUCHARA MINE

intersection having been dug out long ago. In still other cases, like the veins of the Alacran or the neighboring Reforma vein, we have recurrent lenses of mineral with nothing in the way of an intersection immediately near them. On the other hand, a case occurs in the San Miguel Tlaxpampa mine that shows the reverse condition (see Fig. 18). A cross-vein of great importance on the principal level intersects the lodes at their greatest known points of mineralization, indicating by its filling and other conditions that the intersection was largely responsible for the orebody.

From these examples and many others that might be added, we see that orebodies in this district do not occur always at or immediately close to the intersections of veins. The better way to look at such intersections would be as Nature's method of bringing in the watery solutions that effect the precipitation of ore in the older veins. In all the cases cited, the fractures are of varying age and the filling of the different veins is strikingly individual,

FIG. 18

so that in the same mine one can always tell from which vein a given piece of ore came. Usually the oldest vein is highly silicious and the ground has been re-opened by the later fracturing, which allows the new solutions to enter and find their way into the silicious solution in which precipitation is to take place. The intersections,

re-opened and will be available for study. The water in the bottom level is warmer than the body temperature. The Chontalpan mine is the next deepest, and is probably the most extensively developed at the present time, of the mines in this district. The adit-level is 160 m. below the outcrop, and the inclined shaft on the vein, by which development has been done in depth, is over 200 m. deep from the adit down to the seventh level. The mine may be taken as the type of the district, for purposes of study, with a total depth of 360 metres.

The Chontalpan vein system is complex, and the features common to Tertiary ore deposits formed at moderate and shallow depths are well illustrated. An especially striking feature is the tendency of the numerous veins to unite in depth, with abrupt changes of dip.

The Chontalpan vein system has so many branches that it is convenient to regard them as three different sets

FIG. 19. JUNCTION OF VEINS IN THE SAN MIGUEL TLAXPAMPA MINE

of fractures separated by short time-intervals. They all have an easterly dip, varying from 50° to 60°; the narrow hanging-wall veins constitute the first group; the somewhat wider foot-wall stringers make the second group; and the strongest fracture, passing through both the other groups and making an approximately straight

channel, constitutes the principal vein of the deposit. It will be evident from the sketch (Fig. 20), that the smaller veins are really mere branches or offshoots from the principal fracture. The resulting channel is very irregular and the distribution of ore-shoots is equally so. The ore is seldom found at, or immediately close to, the intersections; rather it begins a little away from them, as though deposition sought to take place in spots removed from disturbance. Very interesting examples of this are found in the hanging-wall veins, which at their coming together with the main channel are only a few fingers wide. On following them they widen out to valuable deposits, until one again approaches the main channel, when the ore again becomes narrower and finally pinches at the intersection. The best hanging-wall body found in recent years was discovered by exploration based on

pitch of the ore-shoot and running but a short distance on the level. When we study this chimney, we find that it began practically on the surface, where Jean de la Borde took out the first lenses two centuries ago. It has been followed down ever since on its southerly pitch, the lenses of ore re-appearing and closing with depth, till our own time, when good ore was taken out of it on the second level and followed down with local contractions as far as the seventh, the present deep level of the mine. A sketch of all these orebodies would show a series of contractions and widenings, just like the Alacran ore-lenses diagrammed in Fig. 16. Between the fifth and sixth levels there is the largest barren space known between lenses; the lens on the sixth was good, but short; and that on the seventh seems to be considerably longer. The extremely rich ore of the middle levels is not found in such

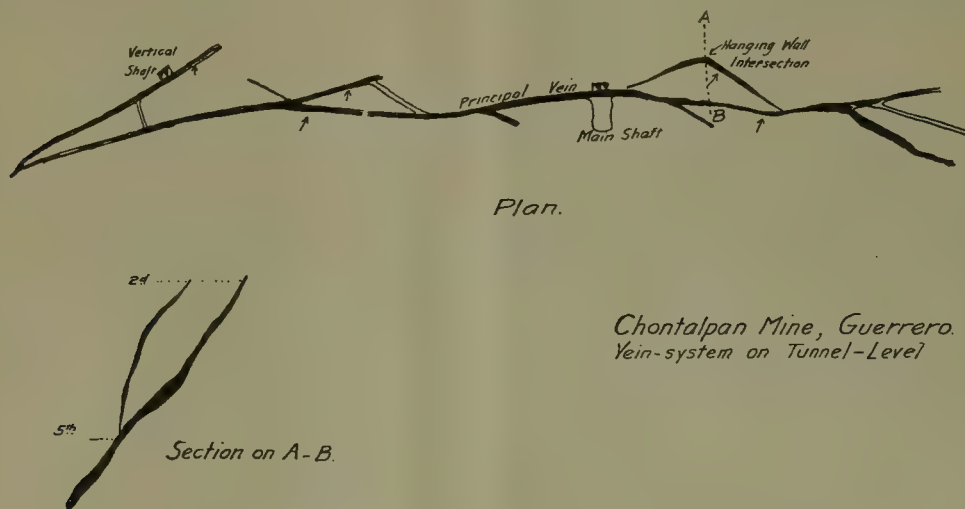

FIG. 20

this reasoning, a cross-cut being driven on the second level to cut the widest part of the supposed lens, which was treated as an intersection of two hanging-wall stringers going in opposite directions. A fine orebody was found carrying exceptionally clean and rich ore, which diminished gradually in size and value in both directions back to the principal vein. Similar work was then done on the lower levels, and the continuation of the same and similar bodies found by this means. In the case of foot-wall veins, driving on them southward from the main fracture has generally showed good mineralization as soon as the miner got away from the intersections.

The most important orebody found in this mine in recent years occurred a little below the fourth level, where a foot-wall vein with a flat dip came together with the principal vein. The extreme foot-wall showed a great deal of shale, and the effect of it was evident in the large amount of zinc and lead in the ore; but silver minerals were so abundant as to make the deposit very valuable. The impregnation of the wall-rock between the two veins made pay-ore at one point, five metres wide. When it is remembered that in these veins 70 cm. is an excellent stoping-width, the result can be appreciated. The deposit, of course, was a chimney, going down with the

abundance in the bottom, but there is really no essential difference in the mineralization. I should say that we have here the same phenomenon as at Alacran, that is, the precipitation of silver mineral in a series of lenses under each other, following a definite pitch dependent on circulation currents, and separated from each other by barren vein-filling.

The same habit of enrichment is noted at other mines in the district, the chimney occurrence being so marked as to have given rise to the term *rosario*, that is, rosary, to describe the formation, like a string of beads; the lenses of ore being the beads, strung out one below the other on the thread of mineralization. The secret of getting ore therefore is to sink on known chimneys, passing through the patches of barren vein-matter that occur between orebodies.

The veins of the district have a marked tendency to come together in depth, this being especially the case at Chontalpan. In depth therefore the ground will have a tendency to be less fractured, and as much of the enrichment is distinctly from late solutions, the question of persistence resolves itself into a study of the degree of fracturing that may be expected in depth in a given deposit. In general, deposition of minerals seems to have

begun on the vein-walls, beginning with galena and zinc, the former coming first, followed by distinct banding of the sphalerite. Ribbon structure is common; mineralization worked its way toward the centre of the fractures, which are quite commonly still open channels. Scale-noids of calcite and fine long quartz crystals sometimes occur in these open spaces, with excellent crystals of ruby silver, argentite, and stephanite, the last rarely. The ruby often comes in scales, stains, and crystals, in minute fractures in the calcite or on the surface of calcite crystals. It is quite evident that the making of pay-ore in these veins is largely a matter of secondary enrichment through the carrying down of silver minerals into the chimneys, that is, it is dependent on the thoroughness of the secondary fracturing. The Alacran shows rich ore at a total depth below outcrop at present not exceeding 250 metres; Chontalpan shows good ore at 340 m.; San Miguel Tlaxpampa, at 240 m. The best information available on Dios Nos Guia would indicate the critical depth as about 300 m. I should say that enrichment to pay-ore in this district should extend to a total depth below outcrop of about 450 metres. Thus the deposits are typically Tertiary.

Similar deposits, with the chimney feature more or less in evidence, occur at Noxtepec, Pregones, and Taxco. The deposits of Noxtepec are narrow, but very rich, veins, usually carrying gold, and the small orebodies go down, one below the other, strikingly in the rosary form. The best-known example is the Xitinga. About half-way between Zacualpan and Taxco are the Pregones mines, of which the old Negrillas is the most important. Here the veins are sometimes very wide, that of Negrillas being between 4 and 8 metres of brecciated quartz, with the better enrichment on the foot-wall. The condition is complicated by the presence of a black, heavy, basic andesite on the foot-wall of the deposit, giving rise to contact phenomena. An interesting feature is the cinabar vein that is part of the Negrillas lode.

Production of Copper in the United States, 1913 to 1919

In the following table the production is apportioned to the States in which the copper was mined. The figures represent the content of fine copper in the blister produced and the smelter output of ingot and anode-copper from Michigan.

*Figures are in pounds.

Lead Production

Ordinarily the United States produces about 50% of the world's supply of lead, but this production is insufficient at the present time to meet the demands for home consumption. During the past year lead has been imported from England, Australia, and Spain, and some lead which was exported to England was re-imported. Lead which in normal times was produced in Mexico, and passed through the United States in bond for exportation to European countries, has recently been held here to satisfy our own demands. The supply of lead in this country, and the changes in lead stocks for the first half of 1920, as compared with the same period of last year, are interestingly set forth in the following figures from the Metal Bulletin:

	1919, tons	1920, tons
Government stocks, January 1	62,852	54,078
Imports, January to June	132,258	62,433
Available supply	215,110	117,408
Exports, January to June	6,579	29,725
Left for home consumption	198,531	88,684

The three most important uses for lead are in the manufacture of white lead for the paint industry, which requires over 175,000 tons annually; in the manufacture of storage-batteries, which absorbs over 150,000 tons of lead annually, and has increased between 50% and 100% per annum during the last three or four years; and in the manufacture of cables and conduits. The battery trade has been increasing rapidly in importance, due to wider application of storage-batteries for starting and lighting purposes on automobiles, for mine-locomotives, for the operation of small motors in industrial plants, and for farm lighting-plants. Building operations have been falling below normal requirements all over the country, and are now forcing a big demand for paint and plumbing supplies, which helps to swell the total demand for lead to a tonnage which exceeds production. In view of the increasing demand for lead and lead products, the absence of any reserve supply of the metal, and the inability of lead producers to materially augment their production, lead is in a very strong statistical position, and is likely to remain so for some time to come, in spite of the fact that the present price of the metal is much higher than obtained over a long period of time prior to the War.

THE volume of the salt in the ocean, according to the U. S. Geological Survey, is enough to cover the entire surface of the United States to a depth of 8500 feet.

Roasting and Chloridizing of Bolivian Silver-Tin Ores

By M. G. F. SOHNLEIN

*In the metallurgical treatment of sulphide silver-tin ores mined at Oruro, Potosí, and Chocaya, the most important and difficult step is chloridizing-roasting. The ores are mined chiefly from veins in rhyolite, a detailed description of which can be found in most textbooks on ore deposits. The chief gangue minerals are pyrite and quartz, and the silver content is derived from tetrahedrite, jamesonite, stibnite, and cylindrite. Most of the tin is present in the form of a rather impure cassiterite, which forms microcrystalline aggregates of varying richness with quartz and pyrite; occasionally some tin is found as stannite, cylindrite, and other complex sulphantimonates. The silver content of the minerals that compose the ore is approximately as follows: pyrite, 3 to 5 oz. per ton; jamesonite, 30 to 50 oz.; stibnite, 30 to 150 oz.; cylindrite, 200 to 300 oz.; tetrahedrite, 500 to 3000 oz. Occasionally some ruby-silver ore is found, but it is rare. In the mines of Oruro, which are the deepest in the sulphide zone, tetrahedrite has nearly disappeared, stibnite, jamesonite, and, in the deepest levels, cylindrite taking its place.

At present there are six mills treating this ore, two at Potosí, two at Chocaya, one at Poopo, and one at Machacamarca. The ore is crushed dry, given a chloridizing roast, leached with water and hyposulphite solution (or with brine) to extract gold, silver, and copper, and concentrated for tin with or without re-grinding.

Between 1890 and 1900, amalgamation was replaced by leaching with either hyposulphite solution or brine. It is remarkable that tailings from high-grade ore treated by amalgamation and those derived from ores of much lower grade that have been leached contain about the same amount of silver, namely, from 5 to 7 oz. per ton. The percentage of chloridizing that can be obtained is not directly proportional to the silver content of the ore, but it seems as if the quantity of silver that cannot be converted into chloride is more or less constant. For instance, after roasting on ore containing 25 oz. per ton, the amount of silver that cannot be chloridized will be 5 to 6 oz. per ton; whereas, with ore of 100 oz. per ton, after roasting, there will be from 8 to 9 oz. of insoluble silver. The silver that has not been chloridized and is left in the tailing after amalgamation or leaching cannot be dissolved by cyanide or any other commercial solvent known to me. Only a small proportion of it is contained in sulphides that have remained undecomposed owing to imperfect roasting; if these tailings, after fine grinding, are treated by flotation, a small amount of concentrate having about the same silver content as the original ore can be obtained, but the amount extracted is insufficient to pay for this treatment.

*Abstract from a paper presented at the Lake Superior meeting of the A. I. M. & M. E. in August 1920.

On account of the difficulty, expense, and silver loss connected with chloridizing-roasting, more direct treatments have been tried for these ores. Agitating the raw ore with cyanide or bromine cyanide after fine grinding is absolutely ineffective; neither can commercial results be obtained by attempting to decompose the sulphantimonates with metallic aluminum, followed by cyanide treatment. This experimenting was carried out chiefly by one of the best known ore-testing laboratories in the United States. Cyanide consumption on either raw or roasted ore was excessive, and the extraction obtained by agitating the finely-ground roasted and chloridized ore with cyanide was not better than by leaching the same material at 16-mesh with hyposulphite. Therefore, thus far the old method has proved to be the only way of treating these ores; and to increase the mill capacity and decrease the cost, it was necessary to find a mechanical furnace that would perform roasting and chloridizing as well, or better, than the old hand-rabbed reverberatory furnaces.

Chloridizing is simple and quick if salt is added at the correct stage of the roast. If salt is mixed with the ore before nearly all the sulphur has been converted into sulphates, it will retard roasting and increase volatilization losses; besides, salt is consumed unnecessarily. If the salt is added too late, it will fail to react properly and too low a proportion of silver will be converted into chloride. In hand-rabbed furnaces, the correct amount of salt is 3.5% for an ore of 25 oz. per ton and 5% for 50-oz. ore. An excess of salt has no particularly harmful effect on the process, but the excess is left undecomposed in the roasted ore, and during the water-wash that precedes hyposulphite leaching, it forms brine which dissolves silver chloride.

Usually the hand-rabbed reverberatory furnace has one continuous hearth, 10 ft. wide, divided into three sections 10 ft. long. There is a drop of 4 in. from one section to the other, the highest being next to the flue, where the raw ore is charged through a drop hole in the arch. A charge of 700 kg. is brought into the furnace and rabbled until it ignites. During normal operation there is a charge in each section of the hearth and care is taken that no ore is rabbled into the section lower down than it belongs. If the charge on the third section is so far roasted that it shows but a few sparks when rabbling, the salt is shoveled into the furnace. The decrepitation of the salt causes violent dusting; therefore, the draft of the furnace is shut off until decrepitation ceases. After the damper is again opened, the charge is rabbled until chloridizing is completed, when the ore will not flow, but packs together somewhat like snow and stands up with nearly vertical sides. The chloridizing takes a little less than one hour in these furnaces; once the ore begins to

pack, it is useless to continue rabbling, because the amount of chloridizing is not increased. If worked by two men, one furnace has a capacity of 4 to 4.5 metric tons per 24 hours. A little taquia fuel is used during chloridizing, because it is not possible to rabble the charge during chloridizing as continuously as during oxidizing, on account of the corrosive fumes that escape through the working-doors, for, to keep down the volatilization losses, the furnace is worked with reduced draft.

A charge remains about 4 hours in each section and is in the furnace altogether 12 hours, of which less than 1 hour is used for chloridizing. It would therefore be a mistake to try to chloridize continuously, adding salt to the last hearth or section of some kind of mechanical furnace, because the atmosphere in the furnace would be charged with chlorine, which retards roasting and attacks the metal parts. Moreover, continuous work has the disadvantage that, if ore with insufficient sulphur enters the chloridizing section poor work will be done until conditions are improved, which will take considerable time with a roasting furnace of some size.

Satisfactory metallurgical results are obtained from hand-rabbed furnaces worked by competent men; formerly, these could be found, as chloridizing roasting was practised in Bolivia for generations. The average silver loss caused by dusting and volatilization during a period of several years was calculated to be 6 to 7% at Machacamarca; if the furnace is worked carefully, the loss can be reduced to a lower figure. The cost of roasting was not high, being around \$2 per metric ton, including everything, but as the plants grew in size and tin mining drew a large proportion of the men from the silver mines, it became imperative to use mechanical furnaces.

The first mechanical furnace installed at the Machacamarca plant of the Compañía Minera de Oruro was a six-hearth McDougall with an inside diameter of 14½ ft. It was first used in connection with two hand-rabbed chloridizing furnaces, where the calceines were mixed with salt. The furnace was fed with ordinary run-of-mine ore which contained about 35 oz. of silver per ton and 30% sulphur; the product from the McDougall contained from 4 to 4.5% sulphur. It was soon evident that the silver losses in the McDougall furnace were much higher than in the reverberatory furnaces. The loss of weight during roasting is from 18 to 20% on an ore with about 30% sulphur; therefore, if the raw ore assays 35 oz. per ton, the roasted ore should contain approximately 42 oz. per ton if no silver were lost during roasting. Instead of this, the product from the McDougall furnace assayed, usually, a little less than the raw ore, which proved that at least 20% of the silver passed through the stack. Later tests proved this loss to be much higher. The capacity of the furnace was 20 metric tons per 24 hours when roasting from 30% sulphur to about 4%. Water-cooling was used, because on a 30% sulphur charge the furnace would run so hot that if no particular care was taken, the ore would sinter on the third hearth, causing frequent breakage of rabble teeth. The higher the temperature, the heavier were the silver losses through volatilization. The economy in labor was not as great as had

been expected, because one attendant was needed for the McDougall and four furnace-men were required at the reverberatories for chloridizing. These men could have roasted and chloridized 9 tons per day, using the reverberatories without the McDougall, so that the cost of labor was only reduced to about 45%.

It was therefore evident that the furnace should be used in some other way. For some time the attempt was made to assist chloridizing by feeding salt continuously into the furnace on the fifth hearth. The rabbles were so set that on this hearth the ore was moved from the periphery to the centre, so that, if salt was fed through one of the working-doors on the fifth hearth, chloridizing took place on the entire surface of the fifth and sixth hearths. But at this point the ore was not sufficiently roasted to react well with the salt, and the final product from the furnace contained too much sulphur and unchloridized silver to allow dispensing with the reverberatories to finish the work. Later, in order to reduce the heavy losses of silver, the furnace was used only for roasting ore containing from 12 to 15 oz. of silver per ton with about 25% sulphur, but even on this material the silver losses were entirely too high.

The charge for the McDougall furnace is now prepared by mixing low-grade fines of run-of-mine ore with high sulphur content with silver-tin ore which carries only 15 to 20% sulphur. When working on this ore the furnace has a maximum capacity of 22 metric tons per 24 hours and delivers its product to one reverberatory furnace for finishing and chloridizing instead of to two furnaces as was the former practice. On ore with more than 30% sulphur, the capacity is only 17 tons. No fuel is used in the McDougall, but a small amount must be supplied to the reverberatory furnace so as to keep its temperature high enough for continuous chloridizing. The difficulty common to all continuous chloridizing is experienced here—slight variations in the McDougall furnace caused by different compositions of the ore, etc., are at once reflected in the results. An attempt to remedy this was made by placing a small bin between the McDougall and the reverberatory, where the partly roasted ore could be stored, if it came down with too much sulphur. With this arrangement, two men working at the reverberatory furnace could finish roasting to the desired point without having to add the salt, and if the ore came down with too much sulphur, the charge to the furnace could be at once reduced. But it takes several hours to bring the McDougall furnace back to proper conditions, and if too much half-roasted ore was held in the bin, it became too cold for chloridizing, so that this arrangement was not satisfactory. Often some of the ore had to be chloridized before it was properly roasted to prevent its becoming so cold that it would spoil the work of the reverberatory roaster altogether. If, on the other hand, the ore came down too much oxidized, chloridizing would be bad because the salt could not react properly with the ore. There was no remedy for this, except mixing with elemental sulphur before chloridizing, which procedure is far too complicated and too expensive for practical work.

Losses of silver through dusting and volatilizing can be prevented by passing the roaster gases through a Cottrell precipitator. Experiments made by a representative of the International Precipitation Co. showed that 9500 cu. ft. of gas containing 0.32 gm. of solids passed each minute out of the stack of the McDougall furnace. Therefore, 4300 kg. of dust was carried away per 24 hours. At that time the feed to the furnace was 22,400 kg. per 24 hours of ore carrying 670 gm. silver per ton. The sample collected in the filter assayed 1070 gm. per ton; therefore, a little over 30% of all the silver that goes to the furnace is lost through the stack. The flue-dust is a mixture of totally oxidized, half-oxidized, and raw ore, and contains considerable antimony trioxide. The erection of a Cottrell treater alone would not have solved the problem, for the chief difficulty was the disposal of the dust. (1) It might be returned to the furnace feed; (2) it might be fed, together with raw ore, to one or more of the hand-rabbed reverberatory furnaces; (3) it might be treated separately, without further roasting, by some hydro-metallurgical process.

The first method has the advantage of simplicity, but as the gases leave the McDougall furnace at about 180° C., all antimony trioxide driven off would be collected by the Cottrell treater and, since it cannot remain in the furnace on account of the high temperature it would accumulate between the outlet of the McDougall and the Cottrell apparatus, making it necessary to clean the conduits quite frequently, thus causing great irregularity in operating the furnace. It was suggested that the gases be kept so hot that antimony trioxide would not be condensed during their passage through the treater, but this would have been a delicate regulation, and the furnace was not built so as to allow the construction of the Cottrell treater directly on top of it.

The second way, feeding the dust to other furnaces, has the disadvantage that a certain proportion of the dust would again be lost; and although this scheme on the whole would be feasible, and has been frequently practised here with dust caught in the dust-chamber of the McDougall, it is not practicable because it reduces the capacity in the other furnaces.

As the dust is a mixture of raw and roasted ore, it seemed practically impossible to obtain a satisfactory extraction by agitation with brine, cyanide, or hyposulphite solutions. Cyanide and hyposulphite failed to extract appreciable amounts of silver, but nearly 60% could be dissolved by a prolonged agitation of the dust with hot brine, to which a small amount of copper sulphate had been added. The residue of this agitation-leaching was treated by oil-flotation, yielding a product of 41 oz. per ton; this brought the total extraction up to 85%. Afterward an attempt was made to combine the two processes in one operation by agitation with brine and copper sulphate in the flotation machine and adding oil at the same time, but no mineral froth could be formed.

The proposed hydro-metallurgical treatment would therefore have consisted of the following processes: Agitation with brine and copper sulphate, precipitating the

solution on copper and iron; decantation of the solvent and washing once or twice with water; oil-flotation of the residue, filtering and drying the concentrate and feeding it to the reverberatory furnaces together with raw ore.

The next step in experimenting with mechanical roasters at Machacamarcá was the erection of a straight-line, one-hearth Merton furnace with five spindles. This type of furnace was selected because it fitted best in the plant, the hand-rabbed reverberatories having about the same dimensions. In order to get a good idea of the movement of the ore through the furnace, the ironwork was completely erected before the arch was built. Every spindle had but one rabble-arm, which was 5 ft. long, and the rabble-teeth were so placed on the arm that one-half of them project forward about 6 in. and the other half are 6 in. backward. These teeth are alternated, the object being to have the back teeth cut furrows in the ridges made by the front teeth.

In the modified straight-line furnace 85 sq. ft. of hearth-area is required to roast and chloridize one metric ton of ore with over 30% sulphur; in the McDougall furnace 58 sq. ft. of hearth is required, but 10 sq. ft. per ton is necessary to chloridize the product in a reverberatory, so that the capacity of the new furnace per square foot of hearth area is 20% less. If, on the other hand, the modified Merton furnace were built with step-bearings to support the spindles from below, instead of suspending them from the framework above, it would be feasible to drive the rabbles at 5 r.p.m. and to obtain a capacity of five tons per 24 hours, which would be one ton per 68 sq. ft., or exactly the same as the combination of McDougall and hand-reverberatory. But, even if the capacity were considerably lower, the quality of work done is so much superior that loss of capacity is not a great objection.

The intermittent system of working, of course, means a certain loss of capacity. The furnace is working at full capacity only when there is a charge of ore on every hearth; therefore, counting from the moment when a charge has been chloridized, it is working on two charges instead of three during 85 minutes. One-third of the time, or 28 minutes, must be considered as lost, since there are only two charges of ore in the furnace; as the time required for one complete cycle is 4 hours, nearly 12% of the capacity is lost. The difference in time needed to pass a charge of ore from hearth No. 2 to hearth No. 3 and that required to pass it from No. 1 to No. 2 is due to the fact that freshly ignited ore flows more easily than half-roasted ore.

Wherever it is important to obtain a uniform roast, the operation should be conducted in furnaces operated on the intermittent system. If anything goes wrong in a continuous furnace, several hours are required to restore proper working conditions, and in the meantime a product that is not suitable for subsequent treatment must be discharged. In addition to roasting for leaching, this system may be useful when roasting for magnetic-separation, or for differential roasting of complex sulphide ores preceding flotation.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

ROOSEVELT DAM POWER-PLANTS SUPPLY MINING COMPANIES.

BISBEE.—The Shattuck-Arizona company during the month of August is estimated to have produced 10,000 tons of lead ore, assaying 6.5% lead and 8 oz. silver, for treatment in the lead-concentrator which was erected two years ago. It is reported that an engineers' license bill, sponsored by the Arizona chapter of the American Association of Engineers, will be introduced at the coming session of the State Legislature. Under the pro-

Co. is reported. The object of the proposed plant is to furnish power for the mines in northern Yuma and southern Mohave counties, and incidentally to irrigate thousands of acres of farm land.

MARICOPA COUNTY.—In the vicinity of Fish Creek station, on the road between the Roosevelt Dam and Phoenix, development work has been carried on for several years past on a property that is said to be the Lost Dutchman mine, which produced a great deal of coarse gold. Sinking has been in progress in an old shaft that was

MAIN SHAFT AND ORE-BINS AT THE MIAMI COPPER MINE

visions of this bill it will be necessary for all engineers engaged in professional business in the State to secure a license.

NOGALES.—Montana and Eastern capitalists are said to be interested in the famous Sheeby group of mines in the Santa Rita mountains. It has been announced that the new owners will take over the properties on September 1. This property is situated in the Agua Caliente region about 25 miles north-west of Nogales and 12 miles north-east of Tubac. A branch of the Nogales-Tucson short-line reaches within a mile of the mines.

BOUSE.—Development of a big water-power project on Bill Williams river by the Stene Consolidated Copper

found covered over with mesquite timber on which had been packed earth and rock. At 100 ft. samples have been found returning assays of over \$400 per ton. The ore is to be packed down to the main road on burros and then taken by motor-trucks to Mesa, the nearest railroad station.

The receipts from sales of power generated at the Roosevelt Dam last year aggregated more than \$400,000, and it is estimated that a 50% increase may be looked for in paid electric consumption during 1920. The Inspiration Con. Copper Co. has a 36-mile power-line, which connects the station at the Roosevelt Dam with the mine. The Inspiration company not only distributes

power to the mine, mill, and International smelter, but also supplies power to the mines and mills of the Iron Cap Copper Co. at Globe and the Magma Copper Co. at Superior.

GLOBE.—The Van Dyke shaft has been bottomed at 1692 ft. and the lateral development now will be started on levels at 1215 and 1550 ft. Ore on the dip was cut by the shaft at 1180-ft. depth, continuing 40 ft. It is understood to average 6% copper and is believed to be a continuation of the Miami orebody.

Over 300 men were called to the surface from both the Iron Cap and Arizona Commercial mines at Copper Hill last week when a fire alarm was sounded, and volumes of smoke appeared underground, leading to the belief that there was a fire in the mines. It developed, however, that the fire had originated on the surface near the collar of No. 2 shaft of the Arizona Commercial, due to a hot rivet being dropped on top of the shaft timbers. As the No. 2 shaft is a strong downcast, and both the above mines are connected, the smoke was drawn down No. 2 shaft and forced through both the Iron Cap and Arizona Commercial workings. The mine-rescue station was notified and a first-aid force rushed to the scene. However, before they arrived the fire was extinguished and no damage was done.

JEROME.—The entire Verde district is being surveyed for the United Verde and the United Verde Extension mining companies. This is the first time that a complete survey has been made. The Verde Combination is reported to be drilling on its Mescal claim and cores are said to be heavily shot with chalcopyrite. The diamond-drill hole which is being run from the 1300-ft. level has attained a depth of something over 450 ft. It is probable that a drift will be run into this ground if the indications continue favorable. The United Verde Extension now has two furnaces in operation, and the output for August is estimated to be approximately 5,000,000 lb. It is understood that the company has no plans for increasing production and may curtail further if the market for copper does not improve soon. The ore now being smelted averages around 14% copper and includes all the low-grade that is being mined on the 1700-ft. level. Reports received from the Shea Copper Co. state that the tunnel has been advanced a little more than 25 ft. beyond the point at which the raise to the shaft is begun and that more sulphide is showing in the face. The station has been cut for the raise and approximately 30 ft. has been made by the company employees, the remaining portion of the raise being done by contract. It is expected that the connection with the shaft 200 ft. above will be made in about two weeks and that by that time the tunnel will have been advanced to cut the orebody explored on the 325-ft. level.

COLORADO

DIVIDENDS BY CRIPPLE CREEK COMPANIES.—NEW SHIPPERS AT IDAHO SPRINGS.

CRIPPLE CREEK.—The Golden Cycle M. & R. Co. has declared a dividend of \$30,000, payable September 10 to

stock of record August 31. The directors of the Cresson Consolidated Co. passed the September dividend owing to the low grade of the ore now being mined. The Reva G. M. Co., lessee of the Rose Nicol mine, on the north-west slope of Battle mountain, has found rich ore on the 10th level. The vein, just discovered, is believed to be the extension of one in the Captain system of the Portland property adjoining the Rose Nicol on the south and east. Samples taken across eight feet of vein-matter are reported to have shown a gold content of 15 oz. per ton.

CENTRAL CITY.—Taylor and Riddle of Rocky Ford, in sinking a new shaft on their Galatea and Summit claims on Banta hill, have exposed a narrow but rich seam of ore, that assays from 25 to 50 oz. gold per ton. The seam is widening and ore is being sacked for shipment.

Silver-gold ore containing from 4 to 6 ounces of gold per ton has been found by the Quartz Hill Consolidated Mines, Inc., in a cross-cut from the Argo tunnel driven to cut the Phoenix-Burroughs vein at depth.

IDAHO SPRINGS.—The first shipment from the Lone Tree mine in the Freeland district was made last week by the owners, Mayor Moscript and associates, of Idaho Springs. Nathan Shapiro and associates continue steady production from the Roosevelt. The mill is operated steadily on low-grade ore. A 10-in. vein assaying 2 oz. gold, 20 oz. silver, 4% copper, and 38% lead has been opened in the Hampton mine. A shipment is being sacked for consignment to the smelter. The Shafter mine of the Hudson Mining Co. is to be re-equipped with modern machinery and work is to be resumed as soon as the plant is started. The Shafter has a record for heavy production of ore of both milling and smelting grades.

OURAY.—Work is to be started on the Calliope mine, property of Charles Nix, in the Bachelor district. The property has been taken over by a syndicate formed by Max Grossman of Chicago. A mill for the treatment of low-grade ore is to be constructed and equipped, and development is planned. The workings of the Yankee Girl and National Belle mines are being cleaned out by the Diana Silver Syndicate, headed by Burton C. West of Denver and E. Johnson of Kansas City. It is planned to drift on the extension of the Tom Boy vein to its junction with the Laura Dinsmore vein.

MICHIGAN

RECENT IMPROVEMENTS AT THE QUINCY SMELTER.

CALUMET.—When normal conditions are restored in the copper-mining industry, several of the big Michigan producers, particularly Quincy and Calumet & Hecla, will enjoy the fruits of extensive improvements that have been under way for upward of a year. In this connection, attention is directed to Quincy's investments in its smelter and in a new hoist at No. 2 shaft. The hoist will make it possible to mine at much greater depth, while the changes at the smelter will materially reduce smelting costs. The smelter changes include a general remodeling of the plant, in which a new furnace, 16 by 32 ft., is being built. There have been installed in addition a 300-hp. boiler, a 22-ft. casting-machine which will turn out

shapes and anodes, a 12½-ton motor-crane to charge the furnace, a 6-ton crane to serve the casting-room, a slag-pot of 2½ tons capacity operated by a combination trolley and battery-locomotive, and an elevating-truck which will carry the refined copper from the casting-machine to the docks. The capacity of the new furnace will be 130,000 lb. in one charge, which compares with the present maximum of 55,000 lb. The total capacity of the improved plant will be 230,000 lb., compared with 140,000 at present. The casting-machine will be as nearly automatic as possible. The electric locomotive, operating on overhead tracks, will 'spot' the cars for the electric crane and the latter will pick them up and dump the mineral into the furnace. Charging of the furnace now is done by manual labor and is one of the most arduous tasks of the furnace-man, for it must be done in the face of intense heat. Altogether the smelter will contain the newest devices especially adapted to the requirements of a modern plant.

Copper shipments show a little improvement during the week with several comparatively large orders booked for Eastern concerns. One shipload, consisting of about 1,600,000 lb., went out from the Quincy and Copper Range smelters this week, and Calumet made a shipment to the East. There are no orders of importance booked ahead at Calumet's smelters, notwithstanding the fact that the furnaces are operating at capacity.

Coal shipments are coming into local ports with frequency and there appears to be little possibility of a fuel shortage next winter. Cargoes of 10,000 tons are arriving at the Calumet and Copper Range docks, while Quincy has sufficient fuel on hand and in sight to provide its employees with coal at cost. The same plan obtains at Calumet & Hecla and its subsidiary plants, and at the Stanton mines.

It was reported from the East that Osceola contemplated suspension, but this rumor has been denied here. It is announced that the only change during the past two weeks is the operation of the Osceola plant on one shift. This does not affect the Kearsarge branch and the difference in tonnage is negligible. Heretofore, hoisting was done on only one shift, the opposite crew being employed in development. Attention now will be centred chiefly in opening new ground so that quantity production will be possible when conditions improve. The present force is engaged entirely in drifting southward, both in Osceola property and in ground leased from La Salle. Under the conditions that have prevailed for nearly a year, Osceola makes this change advantageously. The same problem that confronts other properties, confronts this mine. It would be cheaper to suspend if such a step were possible, but, by keeping up development work, the way is paved for greater production and the nucleus of an organization is retained. Osceola's daily shipments average from 325 to 360 tons, while the daily shipments of the Kearsarge branch vary from 1350 to 1725 tons. Ahmeek shows a daily output in 'rock' of 2500 tons, or slightly better than the normal for the past six months. This is due largely to the fact that a number of Allouez miners and trammers were added to its force. Isle

Royale's shipments are barely sufficient to keep its own mill operating at capacity, while Superior reports 1200 tons of 'rock' so far this month. White Pine, which it was announced a short time ago was about to suspend, is producing a comparatively small amount of copper and limited production likely will be the rule here in preference to complete suspension.

No. 4 shaft of Mohawk is approaching the so-called 'wide' spot on the 25th level, and within 60 days, or three months, the south drift should cut the freak section of the Kearsarge vein. This remarkable spot on the

A 'SLIDE' ON SHEEP MOUNTAIN, SILVERTON, COLORADO

three levels above was found about 1300 ft. from the shaft and it maintained the unusual width of from 35 to 40 ft. for a length of between 400 and 500 ft. The yield consistently ran from 22 to 25 lb. per ton for the entire distance and there is every reason to hope for a recurrence on the 25th and succeeding levels. Curiously there is comparatively little 'mass' in that particular section, although the other two operating shafts continue to produce a fair amount of native 'mass'. No. 4 shaft, as well as No. 6, is being deepened; the former is approaching the 26th level, and the latter is below the 17th. In No. 5 shaft, drifting north is going ahead and the usual amount of ground is being stoped. One of the most encouraging features of Mohawk's operations is the arrival of Italian workers, who are being given places underground. Most of the new-comers bring word that others are preparing to follow and there is reason to look for an improvement in the labor situation.

An improvement is noted in Mayflower-Old Colony's south drift. Besides containing a better grade of commercial 'rock', the vein is unbroken, which makes it pos-

sible to speed operations. There is no change in the raise in the west cross-cut and the same favorable showing that was revealed a fortnight ago still is exposed. Arcadian Consolidated is pushing its New Baltic shaft to the 600-ft. level with favorable progress. As soon as the sixth level is reached, which should be early this month, a cross-cut of about 15 ft. will be run to the vein. The lode will be opened 125 ft. before sinking is resumed. Two machines are operating two shifts per day, and it is planned to follow this program through the winter, with the 900-ft. level as the objective. From that point a drift will be started south to connect with the drift north on a corresponding level in the New Arcadian shaft.

NEVADA

SILVER PICK COMPANY AT GOLDFIELD ISSUES STATEMENT. PROGRESS AT EUREKA.

GOLDFIELD.—The south-east drift on the 358-ft. level of the Florence is 1050 ft. long and is within 100 ft. of where it is expected the southern extension of the main vein-system of the district will be entered. Work from the west cross-cut has been discontinued, but more work in this territory will be done when the treasury of the company is in better condition, according to reports. Florence lessees, mainly the Development and Cracker Jack, have sent 52 fifty-ton carloads of ore to the Development mill since it started June 15. Mill-returns have not been received by the Florence. The 250-hp., double-drum electric hoist formerly used at the Clermont shaft of the Consolidated has been sold to the Con. Virginia at Virginia City. Arrangements have been made to exchange Gold Bar Extension stock share for share for stock in the Deep Mines, an assessment of one cent per share to be paid by the Gold Bar Extension. This assessment will be paid by the company and not by the stockholders, as was done by the Consolidated. The Silver Pick has issued a statement to stockholders in which it is said "the lease on the Mohawk ground has so far been a disappointment, the ground so far opened up being very spotted and most of the ore developed being too low grade to be sent to the mill". This is a surprise to those interested in the company in view of the glowing reports quoting officials that have been published in the last six months. The report says: "Our superintendent reports, however, that the development so far carried on in the Red Top ground looks very encouraging to get on to a shoot of high-grade ore." In view of the two leases now held "it would be a strange thing if we did not run into a body of high-grade ore sooner or later", according to the report. An instance of a gold-mining company in India that is said to be planning to sink a shaft 6000 ft. from the present depth of 4000 is given as a reason why stockholders "will certainly feel that it is worth while to sink down another 300 ft. in the Silver Pick". The report declares "the mine in India shows that gold mining is nearly the same all over the world, sometimes everything looking very good and other times very poor. Nature seems to work the same everywhere. It is hoped that after reading over this letter carefully you will send us your proxy immediately."

The proxy wanted is for a meeting to be held September 14 to increase the capitalization of the company from 1,500,000 to 2,000,000 shares. The 500,000 shares will be put in the treasury of the company and each stockholder will be given "a chance to subscribe to one-third of a share for every share he is holding on payment of six cents per share". The report closes: "One can never tell what developments we may make in the leased ground during the next 30 days to cause a rise in the stock." A carload of ore assaying \$300 to \$1000 per ton will soon be ready for shipment from the Meuli lease on the Lone Star.

GOLD MOUNTAIN.—At the 169-ft. point the tunnel of the Washington Gold Quartz entered a 5-ft. width of \$8 ore. At 190 ft. an \$18 assay was secured from a 2-ft. width. At 193 ft. a 6-in. width assayed 0.12 oz. gold, 13.48 oz. silver, and 12.2% lead. A fault, the second cut, was entered at 200 ft. and in a drift driven to find the vein beyond the fault there was secured from a 6-in. seam an assay of 0.5 oz. gold, \$11.20 in silver, and 17.5% lead, or a total value of \$43.08. A 50-hp. gas-engine and a three-drill, belt-driven air-compressor have been bought. More buildings have been erected, including a boarding-house; the roads have been repaired and the company soon will increase the force of six men now employed, according to J. K. Turner, a Goldfield engineer, who is in charge of the work.

EUREKA.—Shipments continue to be retarded by a shortage of railroad cars. Only development work is being done in the Croesus, where drifts are being driven in fault-fissures in a search for ore on the 200 and 400-ft. levels. Stopping has been discontinued until the ore-bins are again empty. The Holly recently shipped 200 tons of ore and more is ready for shipment when a new 50-ft. head-frame has been erected and minor repairs have been made in the shaft. The Holly is driving a cross-cut into the Bullwhacker territory. The Locan shaft of the Ruby Hill Development Co. has been unwatered. Four carloads of ore have been shipped and 600 tons remains in the bins. The Climax is shipping slowly ore extracted in driving the Mabel L tunnel and in drifting from it. The Prince recently shipped from the 150-ft. level a carload of \$75 to \$100 ore with a high silver and a low lead content.

SIMON DISTRICT.—A raise from the bottom level of the Simon Silver-Lead has been driven 100 ft. in "high-grade milling ore", according to a report issued by the management. This raise is in the hanging-wall orebody opened on the upper levels. The distance from the sixth to the seventh, or bottom level, is 150 ft. The Simon Contact, adjoining the Simon on the north, has opened "milling ore of good grade", on the 350-ft. level at a point 1400 ft. from the Simon Silver-Lead shaft, according to a report issued by that company. The ore was found in a drift in the extension into Contact ground of the main Simon Silver-Lead vein.

TONOPAH.—Ore 5 ft. wide and assaying \$70 for this width has been found on the 400-ft. level of the New California Tonopah. This ore was opened in a vein parallel

to that from which the Tonopah Mining made shipments when that company worked the mine under an option. Ore is being shipped from the 400, 500, and 600-ft. levels at a rate of 50 to 70 tons weekly and it is planned to increase the output. The shipments are made to a Tonopah mill. There are two main veins, which have been explored to a depth of 700 ft., and a winze is now being sunk from the 700-ft. level. It is thought the two veins join at about 900 feet.

UTAH

VIRGIN GROUND IN SILVER KING COALITION PROPERTY PROMISES WELL.

SALT LAKE CITY.—The thirteenth annual conference of the National Tax Association was held at Salt Lake City from September 6 to 10, inclusive. One session was de-

opened along the O'Brien fissure-system in a new ore-zone. Development between the 1300 and 1500-ft. levels suggests that the new ore opened up in the 'Blood' drift on the 1100-ft. level will persist. An important development is reported in the 'Brown' raise, between the 1200 and 1300-ft. levels, close to the Cavanaugh fissure. This work was undertaken in the hope of finding on the other side of a fault a continuation of the old 'Copper' stope orebody, which, in the early days, produced quantities of bonanza-silver ore. The exposure of high-grade ore in the Brown raise of a character similar to that mined in the old Copper stope, is considered an indication that this rich orebody has been picked up on the other side of the fault.

Shipments of ore from local mines continue to be curtailed on account of the shortage of labor; all properties

SILVER KING COALITION CONCENTRATOR AT PARK CITY, UTAH

voted to the subject of mine taxation. A paper entitled 'Appraisal and Assessment of Non-Metalliferous Mines in Utah' was presented by Prof. William Peterson of the Utah Agricultural College, and Paul Armitage of New York, representing the American Mining Congress, presented an article on 'Net Income as a Factor in Mine Taxation'.

BINGHAM.—The new machine-shop at the Utah Consolidated Mining Co. is nearing completion, as are the new change-rooms. A large force of men is now employed in the grading and concrete work at the company's new concentrating plant in Pine canyon, near the International smelter.

PARK CITY.—Exploration of virgin territory at the property of the Silver King Coalition Mines Co. is pointing to the fact that productivity of ground hitherto unexplored should be as great as that of the older parts of the mine, according to M. J. Dailey, mine manager. On the 1100-ft. level a high-grade silver-lead deposit has been

reporting that many miners and shovelers could be given employment. During the week ending August 27, the Ontario shipped 620 tons; Silver King Coalition, 500; Judge M. & S., 419; Daly-West, 392; Naildriver, 115; New Quincy, 56; and the Keystone, 55, making a total of 2157 tons, as compared with 2279 tons shipped the previous week.

A lease from the Little Bell Consolidated Mining Co. has been taken by the New Quincy Mining Co., according to A. L. Thomas, Sr., secretary and manager of the last-named company. By the agreement the New Quincy has secured the use of the Little Bell equipment, consisting of the hoisting-machinery, compressor-plant, boarding-house, blacksmith-shop, and other buildings. The Little Bell shaft has been sunk to approximately the same depth as the Daly-West 900-ft. level. The above arrangement will benefit the New Quincy company, as it will permit an outside entrance for underground work and will make the company independent in its supply of power and air.

Previously work done in the New Quincy ground has been carried on either from the Ontario drain-tunnel or from the Daly-West 900-ft. level, and power has been supplied by other companies. Under the new arrangement, ore can be taken out through the Daly-West or Ontario tunnel, and waste through the Little Bell shaft. The property of the Little Bell company is adjacent to the New Quincy and the Daly-West, and it is considered to be the last undeveloped mining property in the main part of the district. But 70 ft. lies between the drift on the Little Bell 900-ft. level and a raise being put up from a drift from the Daly-West 900-ft. level in the New Quincy ground to make a connection and work is being pushed to effect a junction as soon as possible.

EUREKA.—It is reported that the Knight interests have arranged to keep a pump in operation at the Ruby Hill shaft. A short time ago, work at the Ruby Hill shaft was stopped, owing to the difficulty experienced in raising money for additional prospecting, so if pumping operations are commenced now the shaft will be in better shape when the time comes to resume work. The water will be used at the Tintic mill where it is badly needed, and the milling company will stand the expense of pumping. The mill is now using about 200 gal. of water per minute for sluicing the tailing.

Stockholders of the Zuma Mining Co. are in receipt of a statement, covering the operations of the company for the year ending July 14, 1920. During that period the company expended \$26,732, and did 898 ft. of drifting, raising, and sinking. P. J. Fennell, the president, states that lack of equipment at the property has been a serious drawback to rapid and economical development work. The main shaft should be deepened, if the ore showing continues to improve. Present work is confined to the 800-ft. level, where a well defined streak of ore is exposed. When the winze from the 800 reaches the 900-ft. level, drifts will be driven both north and south, on the ore-channel. The company at present has a debt of \$22,000. More than 300,000 shares remain in the treasury, out of the original capitalization of 1,000,000 shares.

Shipments from this district for the week ending August 27 totaled 141 cars, of which the Chief Consolidated shipped 42; Tintic Standard, 29; Dragon, 12; Iron Blossom, 10; Mammoth, 9; Eagle & Blue Bell, 7; Grand Central, 6; Centennial-Eureka, 5; Iron King, 5; Bulion-Beck, 3; Grand Central, 2; Swansea, 2; Sunbeam, 2; Victoria, 2; Gemini, 2; Laclede, 1; Victoria, 1; Griggs-Huish Leasing Co., 1. This is an increase of 12 cars over the previous week.

The shaft at the Central Standard property, in the eastern part of the district, is now at a depth of 545 ft., and good progress is being made with the sinking. Delays have been experienced, owing to the fact that the porphyry formation, through which the upper part of the shaft was sunk, continually breaks timbers. There has been no trouble with water recently, as the reservoir on the 400-ft. level takes care of the water from above that point.

WISCONSIN

REVIEW OF OPERATIONS DURING AUGUST.

PLATTEVILLE.—The labor shortage in the district became so intense during the month of August that some operating concerns were barely able to operate. On this account the Wisconsin Zinc Co. suspended underground work at all of its producing mines, and in order to hold the working forces together special attention was given to the re-milling of tailing piles, and with some success. The number of shovelers especially was reduced to the minimum. At the Champion mine, the best producer in the Wisconsin Zinc Co.'s group, but six shovelers were at work when the mine was shut-down, whereas twenty-four men are required. Low prices for zinc ore contributed as well. Low prices sometimes can be met with maximum output but low prices in combination with a shortage of men is a difficult problem. Usually many farm-hands drift into the mines after the threshing season is over, but this year farmers themselves complain of the shortage of help so that little relief can be looked for from this source.

Prices for zinc ore were not satisfactory; the cost of production has been increased by the recent advances in freight-rates, and the higher prices for coal and power. The better grades of zinc ore opened at \$49.25 per ton, base, 60% zinc-assay. No gain was shown on offerings until the third week in the month when the price was advanced on high-grade refinery blende to \$53 per ton. The last week of the month sales were made on a base price of \$52.50; the top price for the month was a little better than \$55 per ton.

Deliveries of zinc ore were made for August, from mines to magnetic-separating plants, by districts as here shown, including shipments of lead ore,

District	Zinc, lb.	Lead, lb.
Benton	6,502,000	172,000
Livingston	5,056,000
Cuba City	2,004,000	66,000
Day Siding	1,214,000	60,000
Galena	1,210,000	76,000
Shullsburg	862,000	66,000
Platteville	474,000
Linden	276,000
Hazel Green	234,000
Highland	60,000
Total	17,892,000	440,000

Shipments of the finished product from separating plants to smelters were made for the month as follows:

Company	Lb.
Mineral Point Zinc Co.	4,960,000
National Zinc Separators	3,158,000
Wisconsin Zinc Co.	2,080,000
Block-House Mining Co.	296,000
Linden Zinc Separators	236,000

Total 10,730,000

Low-grade zinc-ore producers fared poorly all month, and operators who did not suspend piled up big reserves, which at the close of the month was conservatively estimated at more than 12,000 tons. The best price paid for the month was 80c. per unit of zinc in the ore, which

would bring 40% ore up to \$32 per ton, but the penalties reduce this to about \$30. The demand for open-market offerings was lax all month so that little zinc concentrate was sold in this market.

The higher offerings for lead ore, which became established at \$110 per ton, about the first of the month, it was believed would stimulate operators to secure a higher production, but this did not materialize. Such production as was made was held closely and the sales reported for the month were few. Producers sensed even higher offerings and about mid-month some few sales were made as high as \$115 per ton. The ore in reserve in the field is held in expectation that the price will eventually reach \$125. Old workings and shallow mines were invaded by prospectors but without any appreciable increase in produc-

veloped and a sulphuric-acid plant at Cuba City is now making 40 tons of 60° Baume acid, which is marketed promptly in Chicago and Milwaukee.

BRITISH COLUMBIA

PLACER MINING IN PEACE RIVER DISTRICT IS ACTIVE.—NOBLE FIVE MILL IN OPERATION.

HUDSON'S HOPE.—The possibilities of gold-placer mining in the Peace River district is attracting a considerable amount of attention. A number of dredging-leases have been taken out by Chase & Stewart on Nation river, and the ground is to be thoroughly explored. Robert Woods has a couple of scrapers at work on Brenman flat and is said to have obtained good results. The Ingenika

LAKE SHORE MINE AND MILL, AT KIRKLAND LAKE, ONTARIO

tion. Shipments of pyrite fell to the lowest point ever known in this field. It was thought that, when the new acid-works went into commission at Cuba City, a demand of some strength would result, but so far as known none has developed.

The gross recovery of milled ore at mines for the month amounted to 8357 tons, the reserve stocks being reduced 639 tons. Net deliveries to smelters amounted to 5365 tons; carbonate zinc ore, 30 tons; pyrite, 65 tons. The raw ore was distributed with the Mineral Point Zinc Co., 3827 tons; National Separators, 3827; Wisconsin Zinc Co., 1431; Block-House Mining Co., 148; Linden Zinc Co., 130. The high-grade ore was disposed of to the Mineral Point Zinc Co.'s smelters at DePue, 3984 tons; Illinois Zinc Co., 641; American Metal Co., 534; Grasselli Chemical Co., 206. The Mineral Point Zinc Co. has been getting about 75% of all the high-grade blende produced.

Noteworthy undertakings are planned in the field by the New Jersey Zinc Co., following an official survey of the field by staff officers of the syndicate. The Zinc Hill Mining Co. has increased its capital stock from \$300,000 to \$1,000,000; two new mills are planned and an all-steel separator will be built. Several new mines are being de-

velopment Co., a commercial company that has two power-boats plying on Peace river, proposes to investigate the gold possibilities of the Ingen river.

STEWART.—The Hyder Township & Improvement Co. is erecting a wireless plant at Hyder. The plant will be large enough for all commercial needs and will keep the district more in touch with the outside world. Cables have been stretched across the creeks in the Bear River valley at places where the bridges were washed away. This will give temporary relief in getting supplies for use during the winter to those camps that intend to operate. Hand-picked ore, taken from two dikes 15 to 25 ft. wide, respectively, at the Silver Tip mine, is being sacked for shipment.

SLOCAN.—The new 150-ton mill at the Noble Five mine was started on August 23, and is said to be giving satisfaction. The mill comprises jigs, tables, and Callow flotation-cells. With the exception of the Cunningham mill, at Alamo, it is the biggest mill in the Slocan region.

KAMLOOPS.—A local syndicate has bonded the Homestake mine, near here, and will start to develop the two eastern veins at once. The mine has been idle for more than 20 years. There are five veins on the property, all of which are said to contain medium-grade ore. The

syndicate will work the property in conjunction with the Mollie Gibson, and already has let contracts for a considerable amount of work.

TRAIL.—Ore-receipts at the smelter for the week ended August 21 amounted to 8911 tons, of which the Consolidated company's mines contributed 7253 tons. The other shippers were: Bluebell, Riordell, 314 tons; Josie, Rossland, 171 tons; Mandy, Le Pas, 1080 tons; Mollie Hughes, New Denver, 23 tons; Monarch, Field, 36 tons; and Venus, Ciceross, Yukon, 34 tons.

TERRACE.—A good deal of prospecting is being done in this neighborhood, and some silver ore is being mined from several properties. Some good-looking ore is being taken from the Kirkpatrick group, on Kirkpatrick mountain, Cedar river. E. F. Michaud is mining and sacking for shipment silver ore running up to \$300 per ton from his property adjoining the New York group, and ore is being sacked from the New York group for a trial shipment. Mat. Allard is sacking ore containing both gold and silver from the Bear group. Bad transportation conditions are preventing much shipping.

ONTARIO

THE LAKE SHORE PROPERTY.—NIPISSING DECLARES REGULAR AND EXTRA DIVIDENDS.

PORCUPINE.—An important statement in connection with the option held by the Dome Mines on the Dome Extension has been forwarded to the shareholders of the Dome recommending the exercise of the option. It points out that a payable orebody has been proved to occur on the sixth level of the Dome Extension, that the ore-zone indicated by diamond-drilling on the 10th level of the Dome extends at depth into the Dome Extension, and that geological conditions show that other known ore-zones of the Dome, if they continue at depth, must dip into that property. The life of the Dome will therefore be considerably lengthened by the acquisition of the Extension, which is practically certain to be ratified by the shareholders.

Diamond-drilling is being carried on in behalf of British interests on the properties of the Ontario-Porcupine Exploration Co., situated in the south-western part of Mountjoy Township, within a mile of Timmins. A contract has been let calling for a minimum of 4000 ft. of drilling and a maximum of 10,000 ft. Little exploration has so far been done in this part of the Porcupine area, as it has a heavy overburden of sand, gravel, and clay, and trenching to rock is impossible. Success has attended diamond-drilling in other similar localities in the camp, and the operations of the company to ascertain whether the vein systems of the producing mines extend to this distance westward will be watched with interest.

MANITOULIN ISLAND.—A number of oil operators have for some time been at work on Manitoulin island with encouraging results. Some years ago the Standard Oil Co. secured a lease of 30,000 acres and drilled a number of wells, but afterward ceased operations. They have now returned to the field and are again at work. An English syndicate headed by Sir Stopford Brunton has leased

25,000 acres and is drilling. The Kyto Oil Co. of Dayton, Ohio, has found oil in three wells at a depth of 458 ft. and is producing steadily, and several other syndicates and individual operators are in the field.

COBALT.—Announcement is made that the Nipissing Mining Co. will disburse \$600,000 to its shareholders on October 20, payment being made in the form of a regular 5% dividend, plus a bonus of 5%. This will make a total of \$1,800,000 paid during the current year, and a grand total of \$22,140,000 since operations started some 14 years ago. The total amounts to 369% on the company's issued capital. Announcement is also made that the company has purchased an iron mine within 35 miles of New York City.

Early in September, it is stated, the shareholders of the Temiskaming Mining Co. will be asked to participate with the McIntyre-Porcupine Mines, Ltd., in the purchase of extensive coal-lands in Alberta. It is reported that some of the shareholders favor dividend disbursements by the Temiskaming rather than the plan to go into the coal business, but heavy stockholders seem to favor the new venture. Arrangements have been made to explore the diabase sill on the Crown Reserve mine, and a diamond-drill machine will be operated from the fifth level for this purpose. Some small shoots of high-grade ore have been opened up on the old Lumsden mine, and the operators have been encouraged to carry on further exploration and development work.

KIRKLAND LAKE.—The Lake Shore mine, situated in the Kirkland Lake gold area, in Northern Ontario, produces higher grade ore than any other gold mine in Canada. The mill treats 60 tons of ore daily, and recovery has averaged about \$24.90 from each ton since the mill commenced to operate in March 1918. The mine has been developed to a depth of 400 ft., the result of which has been to open up two important orebodies. One of these lies beneath the lake, and contains sections where the average gold content is exceedingly high, \$50 assays being quite frequent over the width of an ordinary stope of from four to six feet. The deposition of the gold is not uniform, the ore-shoots beginning with low-grade material and gaining in richness gradually until exceedingly rich and then gradually falling off to low grade again. These shoots are from 100 ft. upward in length, and no difficulty has been experienced in developing ore far ahead of mill requirements.

It was recently decided to carry operations to a depth of 800 ft., the plan being to open up an intermediate level at a depth of 600 ft. This work is regarded as important, as a continuation of the ore to such a depth would necessitate doubling and possibly trebling the capacity of the mill. Operations are carried on with a force of about 60 men. Although this reveals the fact that but one ton of ore is treated for each man on the payroll, the amount may be expected to increase following the proposed addition to the mill. This performance compares favorably with the leading gold mine of Canada, the Hollinger Consolidated, where about 1½ tons of ore is treated for each man employed, but where operations are on a scale about 28 times greater than the Lake Shore.

CONFERENCE ON STANDARDIZATION IN MINING

The American Mining Congress has undertaken to organize a nation-wide movement looking to the standardization and improvement of mining practice as it pertains to mining machinery and equipment, cost-accounting, safety codes, devices for saving life and time, and co-operative methods as adopted by States and governments in behalf of operators and miners. The status of this movement was finally decided upon at a conference in Chicago on August 30 between officers of the Congress and the officers and representatives of several other organizations. The meeting was held in the Engineers Club, where the visitors were guests of Colonel Warren R. Roberts, who is general chairman of the coal division of the Mining Congress Standardization Committee. Two years ago the work of standardization was taken up by the American Mining Congress and the first committees appointed, with Colonel Roberts as chairman. At the St. Louis meeting of the Mining Congress last fall a three-days session of the sub-committees brought forth an exhaustive report, which later was printed and circulated among engineers and manufacturers. From that preliminary meeting there has grown the largest standardization organization ever developed, and now, with two general sections and sub-sections covering the various phases of the problem facing each division of the mining industry, the membership of the big committee exceeds two hundred specialists. Several meetings have been held to lay the groundwork for future programs. It was to consider how this new and powerful body could best function with established committees and with the most beneficial results that the Chicago conference was called. Dr. P. C. Agnew, secretary of the American Engineering Standards Committee, Mr. Sidney J. Williams, secretary of the National Safety Council, Mr. Bradley Stoughton, secretary of the American Institute of Mining Engineers, Mr. R. V. Norris, a director of the Institute, Mr. O. P. Hood, of the U. S. Bureau of Mines, Mr. J. F. Callbreath, secretary of the American Mining Congress, Colonel Roberts, of the standardization committee of the Congress, and Mr. John T. Burns, assistant-secretary in charge of American Mining Congress convention plans for the Denver meeting in November, were present and spent several hours going over the matter. As a result, a resolution was adopted requesting the American Engineering Standards Committee forthwith to organize a mining-standards committee composed of members selected by the bodies represented at the informal conference. The Mining Congress was urged to proceed with its work and it was announced by Colonel Roberts that plans were soon to be published for a great national conference on standardization, participation in which would be urged upon all bodies of mining and engineering men interested in the mining problems. "It is not the intention of this committee to in any way duplicate the work of existing bodies," said Colonel Roberts after the meeting. "There will be no competition and no friction. The American Mining Congress represents the industry because it is composed entirely of operators, hence, is the industry. We intend to take up and consider all of the standards that have been or may be suggested or adopted by either the Government or voluntary organizations and to make these standards operative and profitable. We will also pro-

pose changes and new standards as our committee by experience and contact with the actual conditions in the mines indicate their value or necessity. The standardization conference in Denver during the annual meeting of the American Mining Congress in November will be, I believe, one of the most important meetings ever held and its influence will be felt permanently in both mining and manufacturing. Among the most necessary things to be developed is to show how standardization has made wonderful progress possible in other lines and how the bituminous and anthracite coal men have materially strengthened their business standing by recent adoption of standardized accounting without which they might have suffered many embarrassments during the strikes and wage conferences." The official invitation now being prepared is signed by Colonel Roberts as chairman of the general committee on the standardization of coal-mining machinery, Mr. Charles A. Mitke of Bisbee as general chairman of the committee on metal-mining machinery, and Mr. Richard A. Parker in behalf of the mining engineering profession.

ARIZONA

Yuma County.—D. M. DeLong, of Fresno, California, and Paul Kimball, of Salt Lake City, have taken over a number of mines in the old silver district in Yuma county. Representatives of the American Smelting & Refining Co. are reported to be making an examination with a view to purchase or lease.

CALIFORNIA

Nevada County.—A. A. Codd, of Reno has been inspecting the Morning Glory and Delhi group of mines near Columbia. —A rich pocket was found in the Alcalde, formerly known as the Kenosha, a week ago in sinking a winze from the 400-ft. level. Two pieces weigh about 200 lb. and contain so much free gold that their value is estimated as high as \$5000. The present company was organized by George W. Root and associates as the Alcalde Gold Mines, and Lloyd Root was placed in charge. —Mr. Coughlin, the county clerk, who was appointed as a Commissioner to determine the mineral or non-mineral character of Section 21, Township 18 North, Range 11 East, near Graniteville, has completed the taking of testimony. This section is a railroad selection and the Forest Service contend that it is more valuable for mineral than for agriculture. Expert testimony was introduced on each side. —The power shortage in Nevada county and in the Mother Lode section has been in no way relieved.

Placer County.—The Pioneer mine at Towle is closed until power is restored. —During a violent thunder-storm last week the lightning struck the 60,000-volt transformer at the Rising Sun mine near Colfax, and following the wires to the 900-ft. level shocked several miners unconscious, but did not otherwise injure them. The damage was \$1000.

Shasta County.—The deed from the Bully Hill Copper Mining & Reduction Co. to the Shasta Zinc & Copper Co. for the Bully Hill mines has been filed for record. Revenue stamps attached show that the consideration was \$433,500. By a bill of sale the Shasta Zinc & Copper Co. acquires also all the stock in the Sacramento Valley & Eastern railway connecting the mines with the Southern Pacific system. The

work of tearing down the Balakalala smelter to get structural steel for buildings of the Shasta Zinc & Copper Co. at Bully Hill is under way. Shortage of men retards the work. The first carload of material has been shipped to Bully Hill. It is well understood locally that the Shasta Zinc & Copper Co., which owns the Bully Hill mines at Winthrop, is negotiating with the Afterthought Copper Co. for the purchase of the Afterthought mine and works at Ingot. Ore in the Afterthought is refractory, but it is believed that it can be treated successfully by the new process being installed by the Jackling company at Bully Hill.

Siskiyou County.—M. Munz and associates of San Francisco have bonded a group of quicksilver mines near Gottville owned by Siskiyou county mining men. The lessees have a crew of 12 men preparing to erect furnaces on the property the coming spring. If the Gottville mines develop well during the winter the lessees will also work on other cinnabar prospects situated along the foothills of the Siskiyou mountains and along Klamath river.

NEVADA

Virginia City.—On September 6 it was reported that 350 miners at Virginia City and Gold Hill walked out, demanding a wage increase to \$6 per day. The scale now is \$5. The only large property in this vicinity not affected by the strike is said to be the Concordia. Miners declared an increase in the price of board made higher wages necessary. The walk-out is not sanctioned by the Miners' Union, it is understood, as the union has a working agreement with the operators which holds until January 1.

Obituary

John George Leyner was killed in an automobile accident near Denver on August 5. He was an American inventor of exceptional ability, a pioneer in the development of rock-drilling and mining appliances. He was born in Boulder county, Colorado, in 1860, being the first white child born

John George Leyner

in that county. He was the son of Peter A. Leyner. He leaves a widow and three adopted children. The mining industry owes much to his genius. To have had a part in reducing the cost of removing rock and ore, as he has done, is an achievement that places him among America's great inventors.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

George A. Deming was in Rhodesia recently.

Charles A. Mitke is visiting southern California.

E. P. Mathewson was recently at Warren, Arizona.

L. Maurice Cockerell has returned from London to Mexico City.

Harry W. Schumacher sailed from New York for Venezuela on August 21.

Karl Eilers, formerly associated with the A. S. & R. Co., is at Salt Lake City.

R. E. McConnell, of Los Angeles, is examining a prospect in Lassen county, California.

Harold A. Titcomb is expected at Palo Alto, California, where he will reside henceforth.

C. Erb Wuensch was at Aspen, Colorado, during the week. He returned recently from San Salvador.

L. C. Graton, geologist for the Calumet & Hecla Mining Co., has returned to Cambridge, Massachusetts.

Robert E. Tally, general superintendent for the United Verde Copper Co., was at Los Angeles last week.

Morris B. Parker is consulting engineer to the California Rand Silver Mining Co., at Randsburg, California.

A. G. McGregor, engineer and specialist in the construction of smelters, is in New York on professional business.

A. P. Anderson, of the U. S. Smelting, Refining & Mining Co., has returned to San Francisco from Juneau, Alaska.

Ralph E. Davis, director of the Wisconsin Mining School at Platteville, Wisconsin, since 1911, has resigned to move to New York.

R. M. Geppert has returned to Minneapolis from an adventurous journey to the headwaters of the Peace river, in British Columbia.

Robert S. Lewis, Professor of Mining in the University of Utah, has returned to Salt Lake City after a vacation at Huntington Lake in California.

Richard Roelofs, formerly manager of the Cresson mine, at Cripple Creek, and now residing at Colorado Springs, visited San Francisco on his way from Arizona.

S. F. Shaw has resigned as superintendent for the American Smelting & Refining Co., to become manager for the Compania Minera La Constancia at Sierra Mojada, Coahuila, Mexico.

N. Thompson, manager for Cammell Laird & Co., at Vancouver, B. C., is here for the purpose of obtaining data on the possibility of establishing an iron and steel industry on this Coast.

J. E. Burgess is making a geological examination at Oatman, Arizona, and will remain there to take part as an expert in forthcoming litigation between the Tom Reed and United Eastern mining companies.

Andover Syverson, for several years chief engineer for the United Verde Extension Mining Co., has severed his connection, and will take charge of the holdings of the United Arizona Copper Co., at Mayer, Arizona.

THE METAL MARKET

METAL PRICES

San Francisco, September 7

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	19.00
Lead, pig, cents per pound.....	9.25-10.25
Platinum, pure, per ounce.....	\$115
Platinum, 10% iridium, per ounce.....	\$165

Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

September 6.—Copper is inactive but steady. Lead is quiet and lower. Zinc is dull but easier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY

A statement issued by Governor Harding, of the Federal Reserve Board, last week seemed to indicate that the management of our central banking system had been listening to criticism from quarters where restrictions on loans were disliked. Mr. Harding hastened to deny that the Board ever acted to discriminate between borrowers, and as far as differentiating between essential and less-essential loans, he said: "The Board is too far removed from the actual detailed situations involved to undertake to do this and has relied on the consistent information and judgment of the local banker to accomplish the Board's purpose sought."

The head of the Reserve Board reiterated the position taken last May, which was that the use of credit should be conserved by lending bankers, although in such a way that production of needed products and the accomplishment of business be not interfered with. The fact of close supervision and restriction of credit by bankers to customers has long been recognized in operation. There has been no secret about it. Bankers have discussed frankly the denial of new credit lines to many applicants and the limiting of existing lines to old clients. If such an attitude had not been taken it is fair to assume that, despite 6 and 7% Reserve Bank re-discount rates, there would have been further broad infusion of credit during the summer instead of the condition of stability, even of moderate contraction, which prevailed in most sections of the country.

Some critics of the Reserve Board and the Reserve Bank were inclined to become excited over Mr. Harding's observations. The argument was heard that the Board was misinformed on its own activities, and that tacit if not actual discrimination between classes of loans had been made at the fountain head of credit management. Doubtless the suggestions of the Reserve Board at the conference with the Federal Advisory Council and Reserve Bank Directors in May had a great deal of moral weight with bankers, but it is reasonable to believe that the direct apportionment of credit has been controlled solely by lending bankers themselves.

CURRENCY AND GOLD RESERVES

The amount of gold reserve of the United States available against notes in actual circulation on July 1, 1920, was more than three times that of any of the nations of Western Europe, according to information in 'Commerce Monthly'. This country had \$2,234,000,000 in gold as against \$4,512,000,000 in notes, giving it a reserve of 49.5% of the paper circulation, a ratio which also far exceeds that of any European country. The nation most nearly approaching this country's percentage of reserve was Great Britain, whose gold holdings amounted to 31.5% of her note circulation, while France on the same date had only 9.6%. Germany and Austria had reserves of only 1.6% and 0.4% respectively. Italy, on September 30, 1919, the latest date for which data are available, possessed a gold reserve of only 7.8% of her paper currency.

Wide differences also are shown to exist between the total amount of notes outstanding in the various countries. The \$4,512,000,000 of paper money in the United States compares with \$16,104,000,000 in Germany and \$12,559,000,000 in Austria-Hungary. Great Britain's note circulation on June 30, 1920, was only \$2,258,000,000 and the French total of notes outstanding at about the same date was equal to \$7,288,000,000. Italy on September 30, 1919, had \$3,157,000,000 of paper outstanding. In giving these amounts the bank has converted the units of foreign currencies into dollars at their respective pairs of exchange.

MONEY AND EXCHANGE

Foreign quotations on September 7 are as follows:

Sterling, dollars:	Cable	3.55 1/4
	Demand	3.56 1/4
Francs, cents:	Cable	6.97
	Demand	6.98
Lire, cents:	Demand	4.55 1/2
Marks, cents:		2.46 1/2

Eastern Metal Market

New York, September 1.

All the markets are extremely inactive and sluggish but the price situation in most cases is steady.

Buying of copper is very light but basic conditions are bullish if anything and prices firm. Quietness pervades the tin market with the price tendency easy.

Prices of lead have declined as well as demand.

There is no life to the zinc market, though prices are steady.

Antimony is unchanged.

IRON AND STEEL

Prices and volume of business in iron and steel are still governed by factors which are out of line with the readjustments going on in other industries, says 'The Iron Age'. New buying is not large, but consumption is on a scale that promises well for operations in the remainder of the year and longer. Buyers and sellers recognize conflicting tendencies and find it hard to strike the balance. Testimony to a freer movement of steel products from the mills is definite. Accumulated stocks are being reduced.

While some Pacific Coast shipyards are bare of work, the two tankers just placed at Vancouver will give one Eastern producer 6700 tons of plates and shapes, while 1000 tons of angles go to a steel works on the coast. There is a report, not yet confirmed, that the Standard Oil Co. will build 17 tankers, of which 12 will be placed with Eastern yards.

COPPER

There has been no change in this market so far as activity or prices are concerned. Buying by domestic consumers continues very light, but there are constantly some foreign orders being put on the books. There are no signs of any easing in prices, the leading producers adhering strictly to the 19c., New York, quotation for both Lake or electrolytic copper for delivery through October. They appear not to be anxious to do any business, possibly anticipating that present conditions and higher costs will force a higher price when demand picks up. Consumers also are apathetic, either because they are comfortably provided for or expect lower prices. The expectation is that because consumption is very heavy, stocks in consumers' hands will soon be cut down to the point where buying will be necessary and that such a moment is due by the middle of September. In the outside market small lots are available at around 18.50 to 18.75c., New York, but offerings are not heavy.

TIN

This market has again passed through a very quiet week. Consumers are showing a little more interest, but this has not yet developed into buying on their part. Neither are sellers forcing their metal. Some future shipment business developed last week at around £285 per ton for a London seller, but this demand was spasmodic and did not broaden into further activity. It is known that consumption of the metal is heavy, but it is difficult to reconcile this with the absence of buying, unless invisible stocks are larger than figured. More business was done on the New York Metal Exchange in the last week than in some time, but it was not large, totaling about 175 tons, the last sales on Monday having been put through at around 46c. This compares with 48c. a week ago, and the decline of about 2c. has been a matter of comment. It cannot be explained by lower exchange and lower markets in London, as these do not obtain at present, but it may be due to nervousness by some sellers who may have offered some metal. Spot Straits tin is quoted today at 45.75c., New York, with the London quotation at £280 per ton as against £271 15s. a week ago. The quotation for spot standard tin there today was £272 per ton

with future standard at £279. The Singapore quotation Monday was £289. Arrivals thus far this month have been 5075 tons with 4270 tons reported afloat.

LEAD

Contrasted with only a few weeks ago the market is very quiet and dull and values have receded further. Today both the New York and St. Louis markets are on a par at 8.75c. with demand light. Consumers are withdrawing, expecting apparently that lead will decline still more. This situation had developed as a result of the improvement which has been of fair proportion. This material is available at 8.75c., New York, for prompt delivery, and it is a fact that it can be imported at no more than 8.50c., New York, duty paid. Prompt American lead is held and sold at 8.87½ to 9c., New York, against 9.25 to 9.37½c. a week ago. The present situation is not unexpected and was even predicted some weeks ago. The leading interest continues its quotation at 8.75c., St. Louis, or 9c., New York.

ZINC

The market has undergone very little change. The offerings of re-shipment prime Western metal from England still hang over it and this is obtainable at 7.90 to 8c., New York. While some business is reported done, it is not believed to be large yet. Certain difficulties attend it, such as the identification of original parcels, as otherwise a duty is imposed. This may retard much buying of this nature. The import movement has not affected the Eastern market yet and may not. It is pointed out that most of the business in this immediate market is in brass special and other high grades and that the imported metal cannot compete effectively or seriously, at least in Western markets. The domestic market for prime Western is quoted largely nominal at 8.10c., St. Louis, or 8.45c., New York, with demand very light from all consumers.

ANTIMONY

The market is unchanged with wholesale lots for early delivery quoted at 7c., New York, duty paid. Jobbing lots rule at 7.25 to 7.50c.

ALUMINUM

There are fairly liberal offerings of Swiss and Norwegian aluminum at around 32c., New York, but demand is light. From the leading interest wholesale lots of virgin metal, 98 to 99% pure, are quoted at 34.90c. f.o.b. producer's plant.

ORES

Tungsten: There has been more business reported than in some time, but prices have not advanced. The foreign market is reported to have gone higher. Quotations here are \$5.25 to \$5.50 per unit, with Chinese ore nominal at \$5 per unit.

Ferro-tungsten is unchanged at 90c. to \$1.05 per pound of contained tungsten, depending on the grade and condition.

Molybdenum: The market is quiet with quotations nominally unchanged at 75c. per pound of MoS₃ in regular concentrates.

Manganese: No business is reported but the market is easier with high-grade ore offered at 65c. per unit, seaboard. Supplies for the ferro-manganese industry seem ample at present.

Manganese-Iron Alloys: The market is quiet with very little business in ferro-manganese or spiegeleisen. British ferro-manganese is offered at \$170, seaboard, for delivery into June 1921, and American alloy can be had on the same basis. Sales are confined to small lots. One British maker refuses to meet the new price, having rejected an offer of \$170, seaboard, on a 1000-ton inquiry. Spiegeleisen is firm at \$80 to \$85, seaboard.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

WIRE-ROPE SLINGS FOR INDUSTRIAL PLANTS

'Roebbling Wire-Rope Slings for Industrial Plants' is the title of a new catalogue that contains the latest information as to the various types of wire-rope slings which are now used in shop and field for handling heavy loads with safety. Numerous illustrations show some of the most recent developments of wire-rope slings as a substitute for manila, chain, and ordinary wire-rope slings. The depreciation of the manila-rope due to exposure and wear, and the uncertainty of the chain-sling due to welds and fatigue of steel are so well known that the safety and reliability of wire-rope slings are emphasized. It is general practice to anneal a chain-sling after it has been in service a short time and there is quite a general impression that such annealing removes all fatigue of metal and restores the chain-sling to its original efficiency. This is a fallacy, for fatigue of steel cannot be removed in the annealing-furnace. The breaking of the chain-sling without warning indicates that the fatigue of steel has reached the critical point. The Roebbling wire-rope sling will show by inspection of the surface the approach of the critical point of fatigue and at the same time will have sufficient reserve strength to safely carry the load. Due to the high strength wire used, the factor of safety is approximately twice that of chain, so the fatigue of steel is not so rapid.

The surface indication of fatigue of steel in wire-rope slings is the breaking of the individual wires. For heavy loads the slings are fabricated of seven strands of 37 wires, 6 strands being twisted about the centre strand, each strand having 18 wires on the outside and 19 wires of the inside. The 18 outside wires, due to their location, are subject to the abrasion and most severe shocks and therefore show fatigue first, giving direct warning of sling depreciation. In the manufacture of Roebbling wire-rope slings only blue-centre steel wire rope is used, a rope made from an extra high-grade steel of such physical qualities that it excels all others for strength and toughness. All endless rope slings are made endless in what is termed 'grommet' construction instead of by splicing. The spliced endless sling is not practicable for general service, due to the fact that it is impossible to protect the rope at points where the six tucks are made. When these tucks are in contact with sharp corners they are displaced and the strength of the sling is therefore reduced and deterioration becomes rapid. The endless grommet is made from one piece of strand and therefore contains only one tuck, occurring at the point where the two ends of the strand are tucked in and form the centre strand of the rope. The point where the tuck occurs is always placed on the equalizing thimble and therefore is fully protected from all abuse.

CATALOGUES FOR ROUGH USAGE

Catalogues issued by manufacturers of machinery, plumbing supplies, automobile parts, etc., are frequently handled by mechanics whose hands are soiled by grime and dirt. The covers soon become so soiled that anyone having clean hands or dressed in 'good' clothes dislikes to handle the book. For a permanent catalogue of this type, a cleanable

cover-material is desirable. For many years such a thing was unknown, but the art of stamping and pasting the edges of pyroxilin-coated book-cover materials was perfected a few years ago. It is now possible for any manufacturer to have a catalogue-cover from which grimy spots can be washed with soap and water without injuring it. The leather substitute is durable and will generally remain sound throughout the life of the catalogue. The cost is necessarily higher than for paper or cheap-cloth covers, but is not so high as to be prohibitive if a manufacturer desires a really permanent catalogue; one that will last and remain in good condition for several months.

BELT-CONVEYORS

A recent attractive publication is 'Conveyor Problems and their Solution', by the Main Belting Co., manufacturers of Leviathan-Anaconda belts. An interesting feature is the summary of the important advantages of belt-conveyor systems over other methods of handling material. They are as follows:

1. **Large Capacity.** A belt-conveyor has greater capacity than any other type. This is because the capacity of any conveyor depends largely upon the speed at which it may be operated. Speeds of 600 ft. per minute are not excessive for the wider belts, while even with the narrower belts, speeds of 200 or 300 ft. per minute are attained without danger of spilling the material carried. These high speeds enable the belt-conveyor to handle tremendous quantities of material, so that for all practical purposes, belt-conveyors may be built to handle any capacity desired.

2. **Power Requirements.** Where belt-conveyors can be used, it is not economical to use screw-conveyors or flight-conveyors, otherwise known as scraper-conveyors. Each of the latter consume about twice the power of a belt-conveyor and their capacity is much smaller in comparison.

3. **Small Maintenance Charges.** The greatest advantage of a belt-conveyor is its extreme simplicity. There is no complicated machinery to get out of order and if the proper attention is given to the belt the total cost of upkeep is extremely moderate even taking into consideration the cost of replacing the belt from time to time.

4. **Accessibility.** The rollers are compact units in themselves, easily accessible when properly installed; and repairs, when necessary, can be made in a short time. The belt itself is in plain view, so that its condition is always apparent, and for that reason it cannot give out unexpectedly.

5. **Protection of Material.** A wide variety of materials may be carried with the maximum of safety on belt-conveyors. In the case of foodstuffs there is no danger from contamination by oil or grease since the material comes in contact only with the belt, and remains stationary upon it after loading until the point of discharge is reached; very little breakage of material occurs. This is important where the material is of such a nature that a reduction from large to small size decreases its value. This condition is met with when conveying sized coal, for example.

6. **Flexibility in Loading and Discharge.** The material

may be loaded on the belt at any point in a variety of ways, either by spouts, mechanical feeders, or by hand, and is discharged either at the end or at intermediate points by means of trippers.

7. Light Weight. Capacity considered, a belt-conveyor is lighter than any other type of conveying equipment. This makes it desirable where the machinery has to be carried on trusses, as in the case of a conveyor carried on a bridge-truss between two buildings. The lighter the conveyor, the lighter may be the construction of the bridge, with consequent saving in cost.

8. Freedom from Shut-down. Compared to screw and flight or scraper conveyors, there is practically no danger of shut-down from choking due to the material becoming packed. When a shut-down does occur, it is of short duration.

DECISION IN DEISTER PATENT SUITS

The U. S. District Court of the State of Indiana has affirmed the decree of the lower courts in the action of the Deister Concentrator Co., appellant v. the Deister Machine Co., appellee. The following is quoted from the opinion:

"Appellant attacks the decree upholding certain claims in three patents covering improvements in concentrating tables, asserting that all the patents are invalid, and that its structures do not infringe any of the claims involved . . .

"Various types of concentrating tables were well known to the trade in 1912. Some were covered by patents, and certain factors in the successful operation of all concentrating tables were well recognized at that date. Among the well known types were the Gilpin County Bumping table, the Gold Coast of Africa table, the Overstrom table, and the Butchart Bent Riffle table.

"From these types, as well as from various patents, we find that riffles were old, resistance planes were old, the reciprocal longitudinal movement and the tipping or tilting of the table were all well known and had been commonly practised for many years prior to the appearance of appellee's tables.

"Appellee's predecessors in title were far from pioneers in the art. They conceived and worked out, however, what they assert was an improvement over other tables. Their new table, which was a combination with most of the elements old, possessed merit because of the location and construction of these elements. A new element was added which, co-operating with the others, doubled, so it is claimed, the capacity of the table without increasing the loss in the tailings, secured a cleaner and greater quantity of ore values and reduced the item of labor cost. There is some evidence to support these assertions. That an increased capacity without loss in the tailings resulted is not seriously disputed . . .

"Appellant insists that, nevertheless, inventive skill was not disclosed. For having discovered the value of the plateau and the incline leading thereto as disclosed in the earlier patents, Deister exercised nothing but an ordinary degree of mechanical skill in making use of successive plateaus. But this is not merely a case of using successive plateaus. The use of each plateau is inseparately connected with the location and the height of the riffles on each plateau, the motion of the tables and use of the water, etc. It is a combination where each element works in conjunction with the other elements.

"In practical operation we find results perhaps not unlike those found in the tables covered by the patents just considered, but, clearly, the steps differ by which the results are attained. In this table an earlier stratification was sought. This was better accomplished by the level table. The inclines leading to the plateau made it possible for the table to be practically level. The incline found in the table in

the patents just considered is absent. Stratification on the plateau and on the main surface was therefore accelerated and also more complete. The abrupt inclines leading to the plateaus operated as effective resistance planes that cut off the gangue and prevented it from passing forward at this point.

"We cannot say that this specific structure, designed to meet a specific problem, was but an exercise of mechanical skill."

COMMERCIAL PARAGRAPHS

The Deister Machine Co. has donated one of its 'Plat-O-Table' concentrators to the University of California for use in its mining department.

The firm of Frost & Wurgler, assayers and metallurgical chemists, succeeds Oscar J. Frost, assayer, of Denver. Mr. Wurgler comes direct from the employ of the American Smelting & Refining Co. He devoted 17 years to assaying, chemical, and research work at its Perth Amboy, Globe, and Durango plants. Mr. Frost counts on continuing his active duties with the firm.

Extensive improvements are under way at the plant of the Pollak Steel Co., Marion, Ohio. The improvements consist of several new buildings and new equipment, the total cost running into a large sum. The products of this plant consist of rolled steel bars and shapes, concrete reinforcing bars, etc. These new improvements are being made to take care of increased production and to cope with the volume of business going to the Marion plant.

Abbot A. Hanks, chemist and metallurgist, has moved his laboratory plant to 624 Sacramento street, San Francisco. Enlarged floor space (about 5500 sq. ft.) has made it possible to transfer the testing equipment of R. E. Noble & Co., whose business was purchased by Mr. Hanks some four years ago, to the new quarters. The activities of the enterprise now include metallurgical work, cement testing, concrete testing, the inspection of rails, machinery, pipe, timber, and other equipment, and sampling work at smelters at various points. Nearly 20 men are employed.

An instructive bulletin, No. 41311, from the press of the General Electric Co., covers the subjects of power-factor correction and more recently, power-factor control through synchronous condensers. For power-factor correction a synchronous condenser always operates over-excited, or supplies leading kva. to the system; and for power-factor control it is regulated automatically to maintain constant receiver voltage, the starting and stopping being made dependent on load and power-factor conditions or a time clock. It then may operate either over-excited or under-excited, supplying leading or lagging kva. to the system. Particularly interesting sections of the bulletin are the data on power-factor, causes and effects of low power-factor, and the application of the synchronous condenser, with several calculations both for power-factor correction and control.

The Uehling Instrument Co., 71 Broadway, New York, has just issued bulletin No. 111 describing 'Style U Uehling CO.' equipment. The design is new, being built in single and multiple forms, the latter serving any number of steam-boilers simultaneously, up to a total of six. The purpose of this equipment is to save fuel by burning it with the proper air-supply. Neglect of this factor is costing power-plant owners heavily. Among the features of the new machine are speedy action, resulting from a new form of aspirator, absence of chemical solutions, greater simplicity, and the unique plan of providing an auxiliary boiler-front 'CO.' indicator, which guides the fireman, while the recorder, installed in the chief engineer's office or superintendent's office, makes a continuous (not intermittent) record showing all changes in boiler adjustments that are conducive to either waste or economy.

TABLE OF CONTENTS

	Page	ARTICLES	Page
EDITORIAL		SMELTING WITH BITUMINOUS COAL IN BLAST-FURNACES	
NOTES	401	By H. C. Robson	409
COPPER PRODUCTION	403	An interesting description of copper-smelting practice at Spassky, Siberia. An unusual slag and no coke. Brick furnaces. Successful results.	
The increased rate of production. An analysis of recent statistics. The production is still above normal. Exports in 1913 and 1914 were abnormal. Consumption promises to increase.		THE BUNKER HILL ENTERPRISE—XII (Continued)	
A QUESTION OF ETHICS	403	By T. A. Rickard	413
An advertiser objects to an editorial because it criticizes the leader of his political party and cancels his advertising. An attempt to dictate a policy. The foolishness of it. The editor's duty is to please the readers, not the advertisers; to extend the scope of the paper by independent criticism, and thereby increase its usefulness as a medium of publicity.		The human side of the business. Actual working time of the 'eight-hour day'. No strike since 1899. Methods by which this satisfactory result is obtained. War activities of employees. The Bunker Hill settlement. Insurance of workmen. The mine is a centre of many small industries.	
A GRIEVANCE	404	THE TREATMENT OF AMERICAN LOW-GRADE COPPER ORES	
Restrictions placed upon the use of electricity. The Californian Railroad Commission curtails the hours in which mining companies can use electric energy. Waste of power in other directions, such as 'electrical houses' and gay resorts.		By An Australian	419
DISCUSSION		An Australian view of our methods in treating these ores. Rolls and ball-mills. Trend toward simplicity. The problem of the carbonate ores.	
CHUQUICAMATA	405	RECOVERY FORMULAE	
By Robert Clarke	405	By Hallet R. Robbins	422
Removal of chlorine from the solutions before electrolyzing.		A set of handy formulae for use in checking ore-dressing operations, with examples of their use.	
THE SAMPLING OF MINES	405	NOTES	
By H. R. Sleeman	405	AMERICAN CAPITAL IN NEW BRUNSWICK	
A reply to recent criticism. Proper use of factors of safety. Some methods not suitable to all cases.		By Colin McKay	412
COPPER DEPOSITS OF LAKE SUPERIOR	407	PUMPING IN THE RAND MINES	421
By S. S. Lang	407	DEPARTMENTS	
Exception taken to some of the theories as to their origin advanced by J. E. Spurr in a recent number of the 'Engineering and Mining Journal'.		REVIEW OF MINING	423
FUME FROM EXPLOSIVES	408	THE MINING SUMMARY	431
By Jeffrey Schweitzer	408	PERSONAL	432
A method for the purification of the air from small amounts of carbon monoxide after blasting.		THE METAL MARKET	433
THE ADVERTISER AND THE EDITOR	408	EASTERN METAL MARKET	434
A Correspondence	408	BOOK REVIEWS	435
		INDUSTRIAL PROGRESS	436

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 31 Nassau St.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

Careful Buyers Consult the Massco Catalogs First

They know that between the covers of these volumes are shown supplies which are recognized as standard the world over—backed by the Massco reputation for square dealing and fair prices. They readily appreciate the benefit to be derived through dealing with **one** house for the purchase of all equipment.

The Massco Line fills every need for mining, milling and smelting plants—all carried in stock in Massco stores and warehouses.

Massco Service is available to you in any part of the world. In putting your problems up to Massco engineers, you are at once enabled to strike the center of the market no matter how remote your location.

In addition to the general Massco Catalogs, special descriptive literature on particular items in the Massco Line will be gladly mailed on request.

AMONG THESE ARE:

The Marcy Mill
The Wilfley Table
Scobey Sampler
Perfection Oil and Acid Feeder
Pierce Amalgamator
Sackett Sand Pump
Krogh Pumps

Massco Ore Feeder
McCool Pulverizer
Samson Crusher
Laboratory Wilfley
Ruth Flotation Machine
Huesser Balance
Lindsay Furnace

Massco Clay Goods
Assay and Laboratory Equipment

T. A. RICKARD, . . . Editor

THE check to the manufacture of automobiles is significant. It is due principally to the action of the Federal Reserve Bank in declining to finance loans secured by sales on the instalment plan. One phase of extravagance after another will have to be abated in the general process of deflation now imminent.

IMMIGRATION is lively, but so also is emigration. From July 1919 to March 1920, inclusive, a total of 265,318 aliens landed in the United States, but during the same period 227,544 left our shores, so that the net gain was only 37,774 in the nine months. In 1914 the total of those arriving was 1,218,000. Recently as many as 17,000 arrived in one week at New York, but the conditions prevailing before the War are far from being restored.

FROM Washington comes the announcement that an experiment station is to be established by the U. S. Bureau of Mines at Rolla, Missouri. It is proposed to conduct research in connection with the lead and zinc mining industries of the Mississippi valley, more particularly the treatment of oxidized lead ores such as are found in certain districts of Missouri. This station, it may be assumed, will be conducted in friendly association with the School of Mines at Rolla, an institution that has turned out many successful and honorable members of the mining profession.

A LETTER dated July 18, 1914, has just reached us from Simferopol, in the Crimea, from a young Russian mining engineer who used to be in Colorado. It speaks volumes for the disorganization of Russia that a letter should be six years late in arrival, and it suggests that many letters written during the War failed of delivery. One does not need to be either generous or imaginative to wonder what has happened to the sender of this letter. Is he in General Wrangel's army? did he join the Czar's troops when War was declared, two weeks after he wrote? or is he numbered among the unregarded slain sacrificed in the Russian people's misdirected effort to gain political and industrial liberty?

APPARENTLY the Bolsheviks are as capable in mining as they are in governing. It is reported, in the 'New York Times', that they have been unable 'to carry out more than part of their 1920 program for mining

gold and platinum in the Ural and the West Siberian regions of Russia'. They proposed to produce 4000 pounds of gold and 3000 pounds of platinum in 1920, but in six months this year they mined only 192 pounds of gold and 241 pounds of platinum. We suspect that it was 'poods' and not 'pounds', but that is a minor detail, the chief point being that they did not come within sight of their "program". One reason is a shortage of labor. Conditions of living under the Red rag are not as comfortable or as healthy as promised.

VIRGINIA CITY is the scene of the latest strike. Several hundred miners have 'walked out', compelling the cessation of work at many mines, with the object of forcing the managers to give them an increase of a dollar per day, that is, \$6 per shift. This is not an opportune time to engage in systematic idleness, but the worse feature of the strike is the fact that it is outlaw, that is, unsanctioned by the union to which the men belong. This union has an agreement with the operators that does not expire until January 1, 1921. Naturally the operators exclaim that the cost of mining just now is excessively high, whereas the cost of living is coming down, and is certain to decline further, but the chief objection to the strike is that it runs counter to the principle of collective bargaining. If the men make contracts collectively and then break those contracts individually, they stultify the whole idea of unionism and compel the employers to work on the 'open shop' system. Nothing could be worse for the laboring man. If he will not play the game honestly, he deserves none of the winnings.

WE take pleasure in publishing this week a description of sundry novel smelting practices in Siberia. It has been our experience that most of the unusual or novel methods introduced into the art of metallurgy originate at the smaller plants, especially at those that lack the ordinary means of communication and transport. This is natural. The large smelting companies endeavor, either by the graduated tariffs of the custom plants, or thanks to the preliminary ore-dressing of private companies, to supply their furnaces with an ideal charge, whereas the company working alone must make the best of what it has, often with instructive results. The feeding of comminuted coal through the tuyeres has been introduced recently into blast-furnace work in this coun-

try and was hailed with considerable enthusiasm as a great improvement, although it seems that only a third of the coke can be substituted advantageously by coal, yet here comes Mr. H. C. Robson with a description of the practice at Spassky where the substitution is complete and the amount used compares favorably with reverberatory practice. The last decade has been marked by the success of the reverberatory in rivalry with the blast-furnace, and if the shaft-furnace is to retain its vogue it must be improved. We believe there is opportunity for this. Mr. Robson points out some of the possibilities, even though all his suggestions may not be applicable to American conditions.

NATURALLY the first delivery of mail by aeroplane from New York has aroused enthusiasm. The aerial mail-carriers have had troubles of one kind or another, and the service cannot as yet be said to be running punctually or smoothly, but that must be expected in the beginning of such an enterprise. It is only eleven years since man's conquest of the air was acclaimed in the person of Louis Blériot, when, on July 25, 1909, he flew across the English channel, from Calais to Dover. Blériot's machine was a monoplane propelled by a 25 horse-power Anzani motor. Since then the aeroplane has been enormously improved in design, speed, and safety. We note that plane No. 151, piloted by Mr. P. J. Murray and arriving in San Francisco on September 11, brought a copy of the 'New York Times' of September 8. That is a happy augury. When Blériot crossed the Channel he ended the isolation of England, and it may well be believed that he did something to diminish the insularity of Englishmen. The delivery of the 'New York Times', one of the best, if not the best, newspaper in our language, within three days of publication is significant. It shortens the intellectual link that binds us to our friends in New York; it promises to lessen the provincialism or sectionalism that marks both sides of this continent; and, above everything, it gives us the lively hope that the day is near when, instead of reading De Young's 'Morning Howl' and Hearst's 'Yellow Yap', we shall be able to read a newspaper that not only gives its readers "all the news that is fit to print" but accompanies it with interesting comment and intelligent criticism.

ONE of the best means of learning wherein the conduct of mining and metallurgical enterprises in foreign countries excels our own is "to see ourselves as others see us". To this end we publish in this issue an article that originally appeared in an Australian review and was written by an Australian for the enlightenment of his countrymen. Although the tone of this article is, for our purpose, a little too complimentary, the points that most attracted the author's attention must have differed in degree or kind from the practice to which he was accustomed, and therefore deserve attention. He points out that simplicity should never be forgotten in mill design. Many a method that has worked satisfactorily in theory has failed in practice because the fine balance required

of the various operations could not be obtained under the rough conditions of actual practice. In his enumeration of the different schemes in use he fails to point out that gravity concentration and froth-flotation are not entirely distinct operations as his list would lead one to believe, that instead of being used in series they may be, and are, used in parallel on classified products, as is done at the Inspiration mill in treating the tailing from the 'rougher' flotation cells. His remark that ball-mills have come to stay overlooks possible successful competition by an improved rod-mill, and there is no mention of disc-crushers, perhaps because their use is more general in preparing ore for leaching than for concentration. Our use of more permanent forms of construction, for mill-buildings, is due not only to the cheapening of cement but also to the longer life confidently anticipated for the larger copper enterprises, which start with millions of tons of ore assured. We welcome such friendly comment as is offered in this article; indeed, we venture to say that our engineers in turn should make themselves better acquainted with Australian practice, more particularly in flotation, for which the metallurgists of Broken Hill have done so much pioneer work.

MECHANICAL energy essential to industry comes from three primary sources, namely coal, petroleum, and water-power. The need for the development of our water-power is not, however, based so much on an actual shortage in the supply of coal as upon its great relative economy. There has been mined in the United States 2.8 billion tons of anthracite and 9.2 billion tons of bituminous coal, while there remain untouched, according to reliable estimates made by the U. S. Geological Survey, 19 billion tons of one and 1500 billion tons of the other kind of coal. In addition, there is a fabulous quantity of lignitic coal from which energy may be obtained when it becomes necessary. The difficulty with coal lies in the fact that under present conditions one-third of the freight carried over the country is coal and we are not able to spare the trains to handle this traffic. There will be relief when the system of burning coal at the mines, to produce electric energy for widespread distribution, is extended. The burning of coal in thousands of scattered and isolated boiler-plants is highly wasteful, and the substitution of petroleum for solid fuel is hardly more efficient. From 1859 to 1917 there was produced in the United States 4.2 billion barrels of oil, leaving 7 billion barrels still to be mined. Considering the rapidity of increasing consumption, it is unsafe to count on this supply, even if helped by imports, to last more than twenty years. There remains then the one source of power that is replenished daily, namely, our streams and rivers. It is estimated that of 59 million available horsepower only 16.6% has as yet been harnessed. The development of high-tension electric transmission has made hydro-electric energy the most efficient form of power yet devised. The largest item charged against a hydro-electric plant, once it is erected, is the interest on the capital invested; and the uncertainty of tenure under the former Federal laws caused corporations to hesitate in

investing their money in such enterprises. The new regulations make reasonable provision for the protection of capital put into hydro-electric enterprises without jeopardizing the interest of the public, and there is evidence already of stimulated interest since the new law became effective last July.

Copper Production

It is generally assumed that the present depression in the copper industry is due to the cessation of European buying since the War and the consequent reduction of output by the producers to an amount much below normal. These mistaken ideas are in large measure dependent on the supposition that the production of copper in the United States has increased at a progressive rate of nearly 10% per annum, that is, not only has the production of copper increased but the rate has also increased. Statistics of recent production were given on page 383 of our last issue. The various tables published giving the production and increase by decades seem to confirm the idea, but plotting the figures by years will show that there have been four periods, in each of which the rate of increase in the production was fairly constant. The first, during which the plants took root, lasted until 1881, and developed an annual rate of increase of a little over three million pounds per annum; the second commenced with the introduction of electric lighting, lasted until 1895, and had an annual rate of increase of 20,000,000 pounds per annum. The third commenced with the general introduction of electric railways and lasted until the War, with a uniform rate of increase of 40,000,000 pounds per annum. The fourth period was that of the duration of the War and was one of supernormal production, not to be considered as forming any part of the normal periods. It is characterized by excessive expansion unwarranted except by urgent necessity. Adding six times forty millions to the production for 1914 (1,150,137,192 pounds) gives 1,390,000,000 as the hypothetical normal production for 1920. Actually it seems to be at a somewhat higher rate, say, 1,500,000,000 pounds. Thus, even with the great reduction from the war-rate, the production is still in excess of what may be considered normal. Omitting 1913 and 1914, exports had risen to 775,000,000 pounds per annum before the War. The figures for 1913 and 1914 are omitted because they indicate that Germany was already preparing for war by making large importations of copper, the apparent per capita consumption being 9½ pounds per annum in 1913 as against 7 pounds in the United States. Our exports have already reached the above pre-war quantity, and with the disorganized state of German monetary and industrial conditions it may be safely concluded that further increases will be gradual. In other words, the present rates of production and export are normal or nearly so. James Douglas pointed out, many years ago, the coincidence of the curves showing corresponding conditions in the iron and copper industries, but since the War this agreement has ceased. The production of copper for 1916-'17-'18 was nearly 60%

greater than that for 1912-'13-'14, while the corresponding increase in the pig-iron production was only 38%. Whether this was due to greater foresight or greater difficulty in developing the industry is beside the question, but it fully accounts for the present large surplus in copper and the fact that the price of pig-iron is 250% above pre-war prices, while that of copper is scarcely any higher. In the face of these conditions and the large stocks, which represent fully eight months export requirements, it must be expected that the improvement in the copper industry will be slow even though it now seems probable that the next few years will see a new period of expansion marked by increased consumption of copper for the electrification of the railways and similar purposes.

A Question of Ethics

On another page we publish the correspondence with an advertiser who undertook to discipline us because we wrote something that did not please him. As a matter of fact he was an advertising agent, who, presumably, acted in accordance with instructions from his principals, a firm of manufacturers at Pittsburgh. For obvious reasons, we forbear from publishing the name of the firm, because it is no part of our province to pillory them or to make personal the remarks that follow herewith. The question is this: Is an advertiser warranted in attempting to dictate the policy of a paper by withdrawing his patronage as soon as the editor criticizes the utterance of a leader of his (the advertiser's) political party? In this case the advertiser objected to an editorial—it was the one on Senator Harding's speech of acceptance—because it had "a distinct Democratic trend". It had nothing of the kind, unless every criticism of a leader of one party involves partisanship with the opposing party. That our depreciation of Senator Harding's speech was not prompted by Democratic bias is something of which we are certain; and for confirmation we refer our advertiser either to Colonel George Harvey or to Judge Hughes, both of whom, we are confident, shared our opinion of the speech. Most, if not all, of the editors of independent papers in this country criticized the speech adversely, and one of the most competent of commentators, Mr. E. S. Martin, the editor of 'Life', found in it an easy target for his urbane humor. Of course, we could mount our high horse and protest loudly against the attempt to dictate to us, for it is obvious that if the Messrs. Blank had their way every paper in which they advertise would have to say only the things that pleased them. As our independence is not endangered by this breach of decorum, we need only state that the attempt will not be placed to the discredit of "the business interests" of the Republican party. Such tactics are not characteristic of any party, even though some persons inebriated by the exuberance of their enthusiasm should essay to make editors 'good' from their personal standpoint. This paper is not partisan in politics, but it does discuss political matters at a time when they are of national importance, for it is the

function of an editor to discuss what is interesting to his readers. We are not committed to the support of the Democratic candidate; on the contrary, we think that Governor Cox has made himself ridiculous over the alleged 'slush' fund and we know that his war record is open to grave reprobation, as, undoubtedly, the Republicans will try to demonstrate before the first Tuesday after the first Monday in November. Both presidential candidates, in our opinion, and in the opinion of other independent editors, are second-rate men, and it seems highly probable that the voters in casting their ballots will be guided more by party affiliations than by enthusiasm for either nominee.

Another, and equally important, question arises: Is it the function of an editor to please his advertisers, or to interest his readers? Of course, his main duty and his proper policy is to please the subscribers and readers by giving them what is interesting. To be interesting any writing must be true and it must be agreeably expressed, for misinformation soon ceases to excite curiosity, and truth embalmed in piffle is not appetizing. We go even so far as to say that the advertiser has no standing as a reader; as a matter of fact he rarely has either the time or the inclination to read the papers in which he advertises; even if he does, the fact that he is pleased or displeased is not a factor in the problem, which is, to print matter that will appeal not to him but to those among the subscribers and readers who are his clients or possibly his clients, that is, buyers of the things he advertises in the paper. Of course, if a paper were unpatriotic, scurrilous, or otherwise abominable, a man or firm would be warranted in ceasing to advertise in it, even if the paper had so large and so effective a clientele that the withdrawal of the advertising patronage involved a loss of business to the advertiser. In short, circumstances might lead a man to cut off his nose to spite his face, but usually it is unwise to do so. The kind of journalism in which we are engaged is clean and independent because we have no direct dealings with our advertisers. We—the editor—look to the subscribers. The business manager looks to the advertisers. If we print what interests our subscribers, then *ipso facto* the paper becomes an effective medium of publicity and the advertising pages become valuable to the manufacturer. The latter would be warranted in complaining if the editor failed to publish matter that engaged the attention of the kind of people to whom he appealed through his advertisement, but he is off his beat when objecting to something that does not please himself. If he happened to be a subscriber, he might cease to subscribe, but, if sagacious, he would not cease to advertise until he had reason to believe that the article or articles that displeased him were also so repugnant to many other readers as to cause them to reject the paper and thereby lessen its usefulness as a medium of publicity. The article that moved Mr. Blank to unfriendly action was not of that kind. It pleased many Republicans; it pleased many others, as we happen to know. We mention this only because it is part of the evidence in the case. As we said in our letter to Mr. Blank, we are sorry to have hurt his

feelings; an editor occasionally writes something that annoys an individual; that is the inevitable consequence of frank criticism and the independent expression of opinion. It is possible to write amiable patter, to avoid contentious subjects, especially politics, to step so slowly and so gingerly as to tread on no corns, to ignore the realities of life; but that is not journalism, because it is uninteresting. The function of true journalism is to give the information on which correct opinion can be formed and to guide the formation of that opinion without fear or favor, with kindness toward all honest men, with malice toward none.

A Grievance

The restrictions placed upon the use of electric power at the mines of this State are proving a serious handicap. A sweeping order has been issued by power companies at the instance of the controlling authority, namely, the Railroad Commission, to the managers of mines compelling them to decrease their consumption of power by at least 20% until such time as the rains come and there is a sufficient supply of the water used for generating electric energy. This 20% curtailment is enforced upon all mines regardless of circumstances, just as the increase in railroad freight-rates was granted by the Director-General of Railroads irrespective of local conditions. We referred last week to the hardship that the increase in freight-rates imposed upon sundry mines and sundry mining communities and how an appeal was made in Utah to the Public Utilities Commission of that State for the purpose of relief on intra-state shipments of ores. Indeed these blanket increases of rates, just like this blanket restriction on the use of power, argue a lack of intelligence, or an excess of laziness, on the part of those in authority. For instance, a small mine is running a small mill; one is dependent upon the other; unless the mill can be run full time, the work in the mine must stop. By the recent order the milling must be curtailed 20% and all this curtailment must be made in the 13 hours from 7 a.m. to 10 p.m. A mine is being unwatered, or the water in a mine is being kept down so that the breaking of ore can proceed on the lower levels; a diminution in the use of power means that the water rises and the work has to stop. In some cases it becomes impracticable to continue operations. We are referring to actual cases, not to imaginary ones. In any event, so many of the gold mines of California are idle on account of the high cost of labor and supplies, or the decreased purchasing power of gold, that it seems both unwise and unfair to place any fresh burdens or restrictions upon the industry. Moreover, while electric power is being denied for useful purposes, it is being expended in exhibits of 'electrical houses', thereby inviting the public to use it for a hundred and one non-essential purposes. Power is taken from the hills behind the mines and conducted to cities where it is used lavishly for illuminating all sorts of non-essential places and performances. It seems to us that in this instance the miners have a real grievance and that it ought to receive the sympathetic consideration of the Railroad Commission of the State of California.

DISCUSSION

Chuquicamata

The Editor:

Sir—On page 280, of your issue of August 21, I have read with interest the transcript of a description of the mines Chuquicamata by W. L. Schurz. There are one or two things in the article that I think are not quite right. He states in one paragraph, "belt-conveyors, more than 1000 ft. long, carry the ground ore to the large leaching-vats, where it is treated with water. There is sufficient sulphur in the ore to form copper sulphate without the introduction of sulphuric acid, although before this fact was discovered the company had installed an elaborate acid plant, since abandoned."

Having been assistant-superintendent of the leaching-plant there for two and one-half years from the time of the starting of the plant, I think that Mr. Schurz is somewhat in error in the paragraph quoted above. What he probably means to say is, that there is sufficient sulphuric acid obtained from the water-soluble copper sulphate in the ore by the regeneration of the acid in the electrolytic plant, to obviate the necessity for adding any manufactured acid; hence the abandonment of the acid plant. It would be a chemical impossibility for water and sulphur to combine and form sulphuric acid to dissolve the copper in the ore.

He has also left out a very important portion of the treatment between the actual solution of the copper in the leaching-tanks and the electrolytic deposition in the tank-house. Owing to the fact that the ore in Chuquicamata is a combination of water-soluble copper sulphate, the basic sulphate (brochantite), and the oxi-chloride (atacamite), with several other minerals of copper of more or less the same nature, the solutions obtained from the leaching of the ore contain an amount of chlorine in combination with copper as cupric chloride (CuCl_2). This chlorine has to be removed before the solutions are delivered to the electrolytic cells. This was done, at the time I left Chile in 1917, by precipitating the chlorine as cuprous chloride (Cu_2Cl_2) in a plant specially built for the purpose. Cement copper was added to the solution at the head of a series of agitation cells and the resultant cuprous chloride settled in Dorr thickeners. The clear liquor with chlorine contents reduced to from 0.5 to 1.5 gm. per litre was sent to the electrolytic plant. The reaction which took place can be expressed by the following formula: $\text{CuCl}_2 + \text{Cu} = \text{Cu}_2\text{Cl}_2$.

The cuprous chloride thus obtained was dissolved in a salt solution and the copper precipitated on scrap-iron as cement copper to be used in the dechloridizing of subsequent plant solutions.

At the time that I was there the copper was deposited on starting-sheets four feet square and the resultant cathodes, weighing about 250 lb. each, were delivered to the smelter. These cathodes were melted in oil-fired reverberatory furnaces and cast into regular wire-bars.

Denver, August 25.

ROBERT CLARKE.

The Sampling of Mines

The Editor:

Sir—During the late discussion on this subject I have been credited (or debited) with an asinine statement that I would limit the applicability of methods of guarding against sampling-errors by means of bulk-samples to cases where errors up to 8% or 10% only were indicated. I have been accused also of trying to apply the idea to cases where it was not intended. Again, I am supposed to have introduced the issue of applying the method to ores of secondary enrichment. I have done none of these things.

I consider that the use of factors of safety becomes more imperative the greater the indicated 'errors' become. As to applying the idea to cases where it was not intended, I was not considering some special person's intentions. I was discussing the best ways of applying an idea. The idea of allowing for a sampling-error on results obtained by hand-sampling is not new. It was familiar to me as a youngster twenty years ago. It was not used under that name; but a proportion was deducted off the average assay-results when estimating the actual value expected to be won when the ore was mined. This allowance, where possible, was based on experience with similar ore; where such data were wanting, the allowance was based upon the judgment and experience of the engineer. It covered both latent sampling-errors and the adventitious admixture of wall-rock.

Mr. Webber has gone further and published a method of ascertaining the 'latent errors'. It seems he did so with special deposits in view. That is no reason why the idea underlying his method should not be applied to other deposits or why other men should not elaborate their own methods of applying the idea or why they should not offer suggestions that may affect Mr. Webber's method as set out by him. In fact, I agree with him in almost all he has written on this subject, and his articles have been most instructive. I do, however, consider that his method of taking governing tests (bulk-samples) at regularly spaced intervals means more work than may be necessary in many instances and that more attention should be given to establishing separate factors of safety for differ-

ent types of ore. Mr. Webber's last article (February 20) certainly largely repairs this omission.

Answering the third charge, I believe I never used the term "secondary enrichment". Certainly it was not in my mind as affecting this subject. I said that the division of the ore, for purposes of security against 'errors', should be based on differences of character of ore, not on empirically chosen measurements (as is done in hand-sampling). I said that such variations would occur mostly vertically, though not wholly so. I had especially in view the change from oxidized or weathered ore to primary or unweathered ore; not on account of enrichment or otherwise, but because of physical differences. These would affect the degree of accuracy of hand-sampling differently. Such ores therefore should have their governing tests made separately.

The following sets out briefly the case as I see it:

Bulk-sampling (whether in form of mill-tests or otherwise) by itself is insufficient. It ignores the law of averages, which is the very essence of sampling. It is not worthy of the name of 'sampling' when applied to a mass, heterogeneous in value.

Hand-sampling must be the basis of any valuation. The more samples (the closer they are taken) the more accurate is the result, other factors being equal. For a given number of samples, heavier samples will give more accurate results. For a given total weight of samples a larger number (smaller individual samples) will give the greater accuracy.

For every deposit or mine there is the happy mean, which combines reasonably accurate results with reasonable amount of work (cost). It is the art of the engineer to judge where that happy mean is. The above remarks do not allow for inherent 'errors' in sampling. If that allowance is not made, fewer samples of greater individual size might in some cases give a closer approximation to true values, because the smaller samples may have a bigger 'error' in each and so a bigger average 'error'.

Hand-samples are liable to errors. It is of the greatest importance to ascertain if possible the degree of those errors. The error in one type of ore in one deposit (or in similar and neighboring ones) may reasonably be expected to be more or less uniform.

The errors in different types of ore may be assumed to be different. If not, the fact is a coincidence. It is reasonable to expect such differences and to arrange the work on that assumption. The logical procedure, therefore, is to secure the sampling-error of each type of ore (if there is more than one in the case) separately. It is desirable in securing the error in each type to perform only such work as is sufficient for that purpose. In the absence of data obtained by previous operations and comparisons, the obvious way to secure the error is to compare results of hand-sampling with that of bulk-sampling, it being understood that the bulk sampling is so performed that 'error' is eliminated.

The obvious way to effect this is to take a bulk-sample in such a way and of such a size as to reduce the factors that cause errors in hand-sampling to a negligible quantity, and to enable the hand-sampling of it to bring suffi-

ciently into play the law of averages. The whole bulk-sample being small in comparison with the deposit, and the number of hand-samples taken of it being small compared with the number taken of the entire deposit, greater care must be exercised in the hand-sampling than is the case with the general sampling. This "greater care" refers to dimensions of channel, etc. It must not be allowed to affect the average 'error' by introducing new factors of error. The same method of hand-sampling must however be used as for the general sampling. Channels should be of the same dimensions, and so on.

There is no reason why the error should vary in different parts of the deposit if the type of ore remains the same. If the character of ore varies in such a way as to preclude its division into a few types, the division of the deposit into regular areas, each one having its governing test made for error, may be necessary; otherwise only a sufficient number of tests are justified to establish the fact that any one type of ore has approximately the same error. The said number of tests suffice as against the average error to be applied to one type of ore. For example, if three tests give closely similar errors for one type, further bulk-sample should be unnecessary. If continued tests give results of more or less wide variation then bulk-samples should be taken until it is felt that the law of averages is satisfied. In the last case it would be advisable that the bulk-samples be taken at regular distances.

Except in cases like the last, the problem of ascertaining the sampling-error for a certain type of ore, is a totally different one from that of sampling a deposit, and the reasons for regular spacing and for large numbers that exist in the latter problem do not exist in the former. Indeed, in one type of ore in one deposit, one bulk-sample might indicate the 'error' correctly. I agree, however, that it would be better not to trust to its doing so.

In a case where areas of weathered and of unaltered ore could be dealt with separately, and where a zone of mixed material lies between them, the sites for bulk-tests for that zone would have to be chosen according to the circumstances. Also the area that each test governed would need to be specially considered.

It is as well to repeat that the above remarks regarding number of bulk-samples infer that the sample is taken so large, and that its sampling is done with such care, that each comparison (governing test) can stand by itself. If this is not done, then a number of bulk-samples would be wanted—to introduce the law of averages. I submit that the former is the more logical and the less costly way of detecting an error, except under special conditions.

It would be an impertinence in a stranger to suggest that in the well-known case of the Alaska Gastineau any precautions may have been missed by the engineers concerned. One does wonder, however, why past experience did not prevent the over-estimates that were made. Had not previous work shown that sampling results indicated higher values than were actually obtained? Was the sampling done in a way different from usual? It would be instructive to know.

Mr. Webber gives an example of his method in taking a

bulk-sample. He makes his channels 30 inches apart and strips his back one foot deep for each new face. In a letter I wrote previously I suggested a similar procedure, but taking the channels two feet apart and stripping the back two feet deep each round. It appears to me that the channels being thus placed equidistant measured both along the strike and the dip is more logical. In the case supposed (a vein or bedded deposit) presumably the reason for channeling from wall to wall is because of the structure being parallel to the walls or because values tend to form a 'grain' that way; the idea being to channel 'across the grain'. If so, I do not see why channels should be closer along one direction than along the other.

H. R. SLEEMAN.

Perth, Western Australia, June 28.

Copper Deposits of Lake Superior

The Editor:

Sir—On the frontispiece of the 'Engineering and Mining Journal' of August 21 was an illustration of a concrete head-frame, entitled 'The Modern Obelisk', and I noted on the right of the illustration, among the list of contents, the subject, 'Origin of the Lake Superior Copper Ores', by J. E. Spurr. I was immediately struck with the fact that the Lake Superior copper ores were also an obelisk or monument to the zeolitic type of copper deposits in basic flows, of which there are a number in the world. On reading Mr. Spurr's article, I was greatly surprised that he was going to destroy the obelisk.

I enjoyed Mr. Spurr's notes, but I do not agree with him that these deposits were formed by igneous-magmatic solutions. I would have agreed with him in 1911 when I went to the Lake Superior copper region after spending several years in districts where the mineral deposits were formed by igneous intrusives and their accompanying magmatic solutions. I propose to put a foundation under the zeolitic obelisk in the form of the suggestion that secondary concentration of very lean zeolitic copper ores by means of ascending solutions and the deposition from these solutions along certain channels formed the rich lodes.

Mr. Spurr states, "that the conglomerates and basaltic flows afford zones for the circulation of powerful ascending mineral-bearing solutions". I agree with him on this point, as I wrote a letter which was published in the 'Journal' of February or March 1919. I stated then: "That the heat given off by deep-seated portions of barren acid intrusive rocks caused circulation of solutions through the traps and assisted in the deposition and concentration of copper in the porous amygdaloid tops of the flows and in some of the conglomerates so that at present quite a few of these porous channels are ore deposits. Most all of the amygdaloidal tops of the flows even if they are slightly copper-bearing, show that there has been intense circulation of waters and a deposition of numerous minerals."

He states, "that these deposits, like many others whose origin is better demonstrated, is of igneous magma origin

and that the solutions injected at a definite period contained, comparatively speaking, little sulphur or iron; that they were rich magma solutions of copper with a little arsenic, cobalt, and nickel".

My idea is that the only solutions that would be low in sulphur and form a native copper deposit would come from the Keweenaw basaltic flows erupted under submarine conditions. The volatile sulphur would easily escape, leaving minerals from which solutions with a chemical content necessary to form native copper deposits could be derived. I do not think that the fact that these ore deposits contain a slight amount of silver, arsenic, cobalt, and nickel indicates igneous magmatic solutions. Why should not these basaltic Keweenaw flows contain these metals? The sills and intrusives have been the mineralizers of silver-nickel-cobalt deposits and copper-nickel deposits in various parts of Canada adjacent to Lake Superior and it is to be expected that Keweenaw flows would contain appreciable amounts of these metals low in sulphur.

The intrusive gabbro at Mt. Bohemia, in Keweenaw county, contains small veins of chalcopyrite, bornite, and chalcocite, showing that the magma was rich in sulphur and indicating the minerals to be expected if a basic igneous magma was the mineralizer and if such solutions were injected into the Keweenaw series.

Mr. Spurr states: "That the concentration of the copper gradually from the enclosing or surrounding rocks is an explanation so evidently unreasonable and inadequate as not to merit a second thought"; and again, "It is perfectly clear therefore, that there is no special virtue in either rock—the ore is not native to either, and hence was introduced from a foreign source".

There are at least 22 conglomerates and sandstones, not including the Nonesuch formation, that are much more porous than the amygdaloidal tops of the flows, except where these show brecciation due to strike-faults. Now, if at a definite period, which would have to be after the Nonesuch formation was laid down, toward the end of the Keweenaw period, solutions lean in sulphur salts but rich in salts of copper were injected, would it not be natural for the solutions to seek the porous conglomerates and sandstones, and would there not be a number of mineralized conglomerates? As it is there are only three disclosed at present, the Calumet & Hecla, Nonesuch (foot-wall beds), and Allouez, while there are more than eight amygdaloids that contain rich copper deposits; these lodes are as follows: Kearsarge, Baltic, Quincy, Osceola, Isle Royale, Atlantic, Mass, Lake, and other lodes of less importance in Ontonagon and Keweenaw counties, which would indicate there might be a special virtue in some of these flows.

The area underlain by the Keweenaw flows is about 50 by 250 miles and most exposures show a very slight amount of native copper, with the ore deposits localized in northern Michigan and other smaller deposits at Isle Royale and Michipicoten islands in Lake Superior. There are Cambrian basaltic flows with interbedded conglomerates showing native copper associated with zeolites in northern Canada from a point west from the Copper

Mine river almost to Hudson bay covering an enormous area.

Geologists cite localities in different parts of the world where zeolitic deposits of native copper in basaltic lavas are formed and some of these are of economic importance. Is it not possible that during any cycle of the eruption of basaltic flows, probably owing to different sources of the various flows or to a segregation in the original magma, that certain flows were richer in their low-grade zeolitic copper ores than others, and that these beds are capable of having economic ore deposits formed in them?

The Lake Superior copper deposits were formed by the heat emanating from local intrusives, causing intense circulation of ascending solutions, forming a secondary concentration of rich copper ores from the original very low-grade or lean zeolitic deposits in basaltic flows. The copper remained in the flows, in which it was originally primary, with very little migration except in a few cases, which caused the formation of rich deposits.

Fume From Explosives

The Editor:

Sir—In your issue of August 28, in an article by D. Harrington and B. W. Dyer, entitled 'Danger from Explosives Fume in Metal Mining', the statement is made that frequently as much as 0.2 to 0.3% carbon monoxide is in air from piles of broken rock several hours after blasting. Ventilation has little, if any, effect on these piles, but I have found that a thorough spraying with water quickly clears them of obnoxious gases. In addition it is well to wet the faces and sides of the openings. The amount of water necessary is not great and it is removed with the broken rock. The general use of water-drills simplifies the operation; connections can be made easily, and the spraying finished in a few minutes. Where water-drills are not in use, water may be brought to the face through the compressed-air pipe. At a certain mine a sump was built at the 350-ft. station to hold the seepage. From this sump a 2-in. pipe was run to the 500-ft. station where it was connected to the compressed-air pipe and either water or compressed air was available at the face by a simple arrangement of the valves. After spraying and before connecting the hose to the drill the pipe should be cleared of water by blowing air through it. The 150-ft. head gave ample pressure at a point more than 1000 ft. from the station.

JEFFREY SCHWEITZER.

San Francisco, August 31.

MINING activities in the Rosario district, Brazil, while never of prime importance, show a tendency to revive after the suspension due to the War. The Corporação Minera Famatina has sent a representative to the United States to study the equipment best suited to replace the water-jacketed furnaces at its copper smelter in Chilecito, Rioja. The company produced 733 metric tons of copper

in seven months, at a financial loss, but the outlook for the future is said to be favorable and a production of 300 tons of metal per month thought possible.

The Advertiser and the Editor

A CORRESPONDENCE

Pittsburgh September 31, 1920

Mining and Scientific Press,

Gentlemen:

Attention: Mr. C. T. Hutchinson, Manager.

Acknowledging your letter dated September 1st, with reference to your rate increase.

Before I discuss with you the subject of next year's contract I would like to have you tell me the editorial policy of your paper.

As you note, the sentiment of the business interests is strongly Republican, and your journal seems to represent in this editorial a distinct Democratic trend.

Two of our clients have called my attention to the above fact, and I would like very much to have an expression from you on the subject.

Yours very truly,

The A. B. Blank Co.

per A. B. Blank.

The A. B. Blank Co.

Gentlemen:

Your letter of the 31st ult. has been shown to me. As editor of the 'M. & S. P.', I regret that anything that I may have written should have hurt your feelings, but I venture to say to you that as an advertiser you have no cause to object to an article that was read with keen interest by many, as I happen to know from letters received on the subject. As a subscriber, you might reasonably refuse to read a paper that annoyed you; as a manufacturer, you might reasonably refuse to advertise in a paper that failed to give you the publicity for which you pay; but I beg to remind you that an editor's duty to advertisers is not to print what pleases them but what interests readers of his paper, with whom the advertisers expect to do business. If the article to which you object had injured the functions of the 'M. & S. P.' as a medium of publicity, you would be justified in your action; it did not; on the contrary, it helped to widen that publicity. It is certain that a large number, if not the majority, of those with whom you do business, even those of your political faith, approved the article to which you object. Our paper is independent in politics; it discusses national politics only when the subject is of commanding interest; when the election is over, you will, I trust, find nothing to annoy you, and much to interest your possible clients, in our pages.

Pending the "evolvment" of "normalcy", I am, my dear Sirs,

Yours very truly,

T. A. RICKARD.

[This interesting subject is discussed on an editorial page.—EDITOR.]

Smelting With Bituminous Coal in Blast-Furnaces

By H. C. ROBSON

For 13 years all the blast-furnaces at the Spassky copper mine, in Siberia, have been operated with coal, for smelting the high-grade ore. As this is unusual, it may be of interest to give the details of practice. The Russian

furnaces erected during the year 1907: inside length of hearth, 19.5 ft.; inside width, 4 ft.; height of tuyeres above the hearth, 18 in.; height of feed-floor above tuyeres, 11 ft. There are 32 tuyeres, 16 on each side, having an internal diameter of $2\frac{1}{4}$ in. The drawing (Fig. 1) of the original blast-furnace gives the chief dimensions, together with the general outline and design.

The hearth of the furnace is made from red brick, with tamped brasque lining; this bottom never gives trouble, as it is always covered with metallic accretions. The fire-walls of the furnace are made from unburned quartz-brick 12 in. thick. The brick superstructure, which is carried on 12-in. girders, is made from red brick on the outside and has a fire-brick lining; the whole is reinforced with cast-iron plates and bound with 6-in. I-beams. There are three charging-doors, all situated on one side, the two settlers

being placed at the extreme ends of the furnace. They measure 5 ft. by 4.5 ft. by 2.66 ft. deep inside.

The charge, ore and limestone, is bedded and all return-

GENERAL VIEW OF THE SMELTER YARD

company that formerly worked the Spassky property used very small blast-furnaces in which they smelted oxidized and roasted ore to black-copper, which was then treated in a scorifying-furnace for the production of an inferior grade of refined copper.

When the present company, the Spassky Copper Mine, Ltd., assumed control, they attempted to make coke from the local coal, but the result was a failure, although it has been proved since then that the coal can be coked without difficulty and that a good quality of coke can be made. A typical analysis of the run-of-mine coal, as used at that time, was as follows: volatile combustible matter, 19%; fixed carbon, 52%; water, 3%; ash, 26%.

Upon the failure to produce satisfactory coke, it was decided to use coal, and a new plant was designed with much larger furnaces and a converting and refining department. For several reasons brick blast-furnaces were erected, instead of the modern water-jacketed furnace. The following points had to be considered: scarcity of water and its hardness (70°), extreme weather conditions (at times the temperature dropped to -42°C.), inferior labor, small percentage of sulphur in the charge, which would be conducive to the formation of black-copper in the furnace and settler.

The following are the chief dimensions of the three

RUSSIAN AND KIRGHIZ WORKMEN

slags are fed separately. The handling of this material was originally done in wheelbarrows, the furnace being fed by shovel. A small beam was fixed in front of each door, so that the charge had to be thrown into the fur-

nace instead of pushing it in; this promoted even distribution of the charge and diminished irregularities in the running of the furnace. The slag and matte run continuously through an open breast into cast-iron settlers, which are lined only with brick on the back side where the slag enters the settler; the rest is protected by coal-ash. Originally the slag overflowed into small pots; these were dumped by hand on a paved floor. The slag, when cool, was broken and loaded into railroad-cars, to be used for ballasting the company's light railroad or thrown over the dump. The ore that was originally smelted in the blast-furnace assayed somewhere around 20% copper, the predominating cuprous mineral being bornite, of the following composition: copper 64%, sulphur 24%, iron 12%; so it will be seen that the amount of sulphur was strictly limited and a certain amount of black-copper was bound to form during smelting operations. In later years, when the lower levels of the mine were being worked, the proportion of sulphur increased.

A most uncommon type of slag was produced; it was more like an iron blast-furnace slag than a copper one. This slag was very fluid as it flowed from the furnace, but chilled at an amazing speed. The following analyses are the yearly averages of slag from the three furnaces:

Year	Cu %	FeO %	CaO %	BaO %	Al ₂ O ₃ %	SiO ₂ %
1913	0.42	6.0	29.5	6.11	6.64	48.86
1914	0.42	6.77	30.1	6.1	6.4	48.5

Owing to the unvarying character of the ore and fluxes, the slag produced was uniform in composition, but the trouble caused by dirty coal was always present, being more pronounced during the winter, when the snow made sorting more difficult. The chief impurity was shale, an undesirable material to smelt even under the best circumstances, and in this plant requiring at least 33% of the flux used in smelting. With the slags mentioned, from 35 to 40% of coal was always used on the furnace charge until easier slags were produced; any attempt to reduce the amount of fuel always resulted in trouble.

The reasons for this high fuel-ratio are numerous: first, the slag produced had a high formation-temperature, the fuel was of inferior grade, the amount of oxidizable sulphur was practically nil, and, as the furnace always ran with a hot-top, a great deal of the fuel was consumed long before it reached the smelting-zone. Under the old conditions a hot-top could not have been avoided because the furnace ran so slowly. During the summer months spraying of the coal and the top of the charge with water was necessary owing to the intense heat, which was nearly unbearable for the men working on the feed-floor. The usual amount of charge smelted per day was only 80 long tons. About two hours each day was occupied in cleaning the settler of black-copper and chilled slag; during this operation it was necessary to bank the furnace. Reverberatory-settlers and numerous other modifications were tried in an effort to avoid this delay, but with little success.

The normal length of the campaign is from 9 to 16 months, when the furnace must be shut-down owing to accretions on the hearth and the frail nature of the fire-walls, which would need incessant patching to permit

continued operation. The method adopted for patching the brick-work of the furnace is as follows: the thin part of the wall is broken away and the charge in the immediate vicinity is scraped out; this cavity is filled by ramming large balls of damp fire-clay into the damp clay with the aid of a pole and a sledge-hammer.

The following layers constitute the 'bed' before ironstone was introduced as a flux, the figures being given in long tons: 30 tons of limestone; 40 tons of ore; 30 tons of limestone; 40 tons of ore; and 3 tons of converter cleanings, etc. The furnace charge, containing about 11% copper, generally consisted of seven barrows, or 56 poods, of 'bed'; two barrows, or 14 poods, of converter and return-slag; and five barrows, or 25 poods, of coal. This charge was found most suitable after repeated experiments with charges of various sizes. The air to the furnaces was delivered by four Thwaites (Root) direct-acting duplex steam-driven blowers. The pressure formerly was from 8 to 12 oz. per square inch, although this pressure was increased during the latter part of 1917 to 24 ounces. After 1914 a varying percentage of ironstone was used on the charge, replacing part of the limestone; this tended to make a free-running slag and reduce the consumption of coal, but the amount of metallic copper-iron accretions increased to such an extent that it almost nullified the advantages, for the bottom of the furnace built up quicker and the settlers were kept open with difficulty. It was not until the latter part of the year 1917 that the best furnace conditions were attained. The ironstone was still further increased and the percentage of fuel cut considerably; a greater volume of high-pressure air was used, until there existed in the smelting-zone a slightly oxidized atmosphere, instead of the highly reducing one that always existed before.

Under the new conditions, as much as 4.5 tons of charge was smelted per square foot of hearth in 24 hours, with a consumption of from 17 to 20% of coal. The furnace ran with a cold top, emitting dense yellow fume of unconsumed hydro-carbons from the distillation of the coal. With the increased rate of smelting the fire-walls of the furnace soon began to show signs of burning out, but this was counteracted by side-feeding the charge, thereby forming a V-shaped channel throughout the length of furnace. In this channel the coal was placed, and trouble from that cause ceased. The top of the charge was so cool under the new conditions that it was possible to enter the furnace through the feed-doors without serious inconvenience.

Fuel was just about half that formerly used, and when it is considered that only about 50% of the coal is available for smelting, it cannot be called excessive. The tuyeres, which used to be bright, were now quite dull. The furnace operated with few irregularities, owing to the faster running and the low-formation temperature of the slag. Typical analyses of slag and matte are given below.

Slag: CuO 50%, FeO 22.5%, CaO 21.0%, BaO, 2.5%, Al₂O₃ 8%, SiO₂ 43.3%.

Matte: Cu 55.0%, Fe 16.8%, S 20.5%.

The following analysis is representative of the ore

coming from the lower levels of the mine, this being the type of ore smelted during the year 1917-'18:

Cu	11.90	%	S	8.31	%
As	0.18		Al ₂ O ₃	2.58	
Sb	0.37		BaSO ₄	11.02	
Pb	0.14		SiO ₂	55.48	
Fe	6.28		CO ₂	0.88	
Mn	0.08		H ₂	0.01	
Ni	0.07		Ag	3 oz. 6 dwt.	
CaO	0.76		Au	5 grains	
MgO	0.26		Moisture	0.08	

The metallic accretions produced in the furnace varied from time to time with the composition of the charge, but the following are typical:

Year	Cu %	Fe %	S %	Conditions
1913	84.33	3.5	..	Only limestone used as flux
1916	23.60	25	0.1	Small percentage of ironstone on the charge
1917	94.6	2.3	..	Large percentage of ironstone on the charge

problem revolves itself into one of correct regulation of the air to burn the gases efficiently under waste-heat boilers; a suitable form of closed-door charging-machine would be necessary and these have already been developed for blast-furnaces smelting iron ore. There is no reason why it should not be accomplished in matte-smelting.

The Freeland type of machine would be suitable for charging the furnace and an automatic carbon-monoxide recorder situated beyond the waste-heat boilers would be necessary to control the air for complete combustion of the waste-gases. The extra air required for complete combustion of the gases could be supplied by a low-pressure fan, driven by a variable-speed motor or steam-engine. The waste-heat boilers might be situated as near

FIG. 1. THE BLAST-FURNACE USED AT SPASSKY

The following are average analyses of flux used in the blast-furnace during 1917:

Ironstone: Fe 45.34%, Al₂O₃ 8.74%, CaO 2.66%, SiO₂ 13.57%.
Limestone: CaO 49.3%, SiO₂ 8.08%.

It is my opinion, after eight years experience with coal-run blast-furnaces, that the use of bituminous coal in matte-smelting of sulphide copper ores could be developed to a greater extent than heretofore and that it would ultimately result in marked economy over the use of coke, if suitably designed equipment were used. In carrying out the above idea I see no difficulties that cannot be overcome. The gas issuing from a furnace running on coal, with a cold top, I know from experience, is easily ignited and burns with a fierce flame. The whole

as possible to the furnace and a combustion-chamber, in which the gases would be burnt before entering the boiler, should be interposed. The rapid smelting would be advantageous, since it would make a free-flowing slag and produce sufficient gas for economical operation of the waste-heat boilers.

Bedding of the charge would ensure proper mixing and small charges should be fed to the furnace at regular intervals to obtain a steady supply of gas of uniform composition.

The most suitable type of coal would contain a small amount of ash and high fixed carbon as compared with the volatile combustible material, and it should not swell on heating. The cost per unit of carbon in such a coal is less than that in coke; therefore, using coal instead of

coke in a matting-furnace with waste-heat boilers attached, all the volatile combustible material contained in the coal could be utilized to produce steam with practically no extra cost. In conclusion, I might point out that the use of coal without the inclusion of waste-heat boilers would probably be cheaper than using coke, but, owing to the explosive nature of the gases, dust could not be caught unless the gases were first burnt before being settled in dust-chambers. Without dust-catching appliances, metal losses would be high and would probably more than offset any gain.

American Capital in New Brunswick

By COLIN McKAY

The mining possibilities of New Brunswick have begun to attract American capital. The International Paper Co. has recently purchased three coal mines in the Grand Lake district, and has made plans to double their present output. The North American Antimony Co., of which Walter F. Dixon, of New York, was the principal organizer, has taken over the interests of the Canadian Antimony Co. at Lake George, and will carry on operations on a considerable scale. More recently a party of New York capitalists made an inspection of the oil-shale areas in Albert county in company with William Pugsley, the Lieutenant Governor of the Province, who is associated with parties controlling large development rights there.

Investigations made by the Canadian Department of Mines show that the oil-shale areas are sufficiently extensive to form the basis of a large industry. Average samples of oil-shale taken by the Department have yielded 60 imperial gallons of oil, or about double the average yield of the shale in Scotland, from which the distillation of oil has been carried on successfully for many years.

Among the New Yorkers who recently inspected the oil-shale areas were experts who have had to do with the development of similar deposits in Colorado, Utah, Wyoming, and Dakota. Owing to their greater richness in oil the shale of New Brunswick will, it is claimed, require a somewhat different treatment from the Scotch shale, but American experience in Colorado and Utah, where the shales have about the same content of oil as in New Brunswick, has developed retorts for the distillation of oil, which, it is said, can be utilized with advantage here.

The three coal mines in the Grand Lake district purchased by the International Paper Co. have a present output of 100 tons per day, which will be increased to 200 tons by October. This district produced only 57,000 tons of coal in 1913, but last year the output was about 250,000 tons, the principal producing companies being controlled by Sir Thomas Tait and Canadian Pacific Railway interests. The coal-seam has an average depth of 36 in. and in many parts is so near the surface that it is mined by stripping the top soil with steam-shovels. Where shaft-mining is employed the average depth at which the seam is found is 40 ft. No deep borings have been made, and the geologic formation does not argue the existence of coal-seams at great depth. Estimates of the amount of

coal in this district vary from 35,000,000 to 150,000,000 tons.

During the War, and since, Grand Lake coal has been exported to Maine, and it is understood that the International Paper Co. has bought mines here for the purpose of supplying coal to its pulp-mills in Maine.

THE mine of the Climax Molybdenum Co. is situated on the south-western slope of Bartlett mountain, 5000 ft. east and 1000 ft. above the company's mill, which is at Climax, Summit county, Colorado, on the crest of the Continental Divide, and at an elevation of 11,300 ft. Climax is 15 miles from Leadville, on the South Park branch of the Colorado & Southern railroad that connects Leadville and Denver. Owing to the altitude, climatic conditions are somewhat severe for practically nine months of the year, but the topography of the country is such that there are no snowslides of any extent, and the mine buildings are so placed as to be immune from such slides as occasionally may be experienced. The mill is built on a relatively flat site remote from any danger of slides. A two-bucket tram delivers the ore to 500-ton bins, which discharge direct to a 20 by 20-in. Blake crusher, where it is crushed to 2-in. size. The ore is then delivered to a conveyor-belt, which takes it to a 400-ton storage bin at the upper terminal of the main tramway to the mill. The main tramway is a 5000-ft. Leschen continuous type, having a capacity of 1000 tons per day, and delivers the ore direct to the mill bins.

The mill was designed by D. F. Haley, and contains two Allis-Chalmers ball-mills, Callow and Janney flotation machines, Goldfield agitating-tanks for dewatering concentrates, Portland filter and steam drier, with accessory blower, pumps, and elevators. A heating plant and fire pump are housed separately. The present capacity is 350 to 400 tons per 24 hours, and the power is derived from a 13,000-volt transmission line.

MANGANESE exported from Brazil is subject to duty by the State in which it is produced, there being no federal export duties on any commodities. The State of Minas Geraes bases its export tax on manganese ore upon the official value of the product, which is fixed monthly by decree. This value, however, does not correspond exactly with the value of the ore in the market. The ratio of the tax was fixed for 1919 at 12%, and remained so until February 1, 1920, when it was reduced to 10%. The tax is payable in Brazilian paper currency. The amount of the tax for February 1920 was \$1.25 per metric ton. As all the manganese ore produced by the State is at present shipped through the port of Rio de Janeiro, each metric ton of ore is subject to a port-tax, payable at the current rate of exchange in Rio de Janeiro. Bahia exported manganese ore for many years. The exploitation, however, has not been continuous, being affected principally by the value of the manganese ore abroad and the Brazilian exchange. When the Brazilian exchange is low the miner makes a reasonable profit. This State tax on manganese ore from January 1 to February 29, 1920, was \$0.805 per metric ton.

THE CHANGE-HOUSE

The Bunker Hill Enterprise—XII (Continued)

The Human Side of the Business; Labor Troubles; Good Management

By T. A. RICKARD

Since 1899 there has been no strike among the Bunker Hill employees. However, at the time I was collecting information for these articles all the important mines of the Coeur d'Alene, except the Bunker Hill, were idle. That was in September 1919. A diagnosis of the disturbance appeared in 'Northwest Mining Truth', of Spokane, on September 3, 1919. It was written by Hillard W. Power. He laid the blame on the general feeling of unrest due to readjustment after the War, the willingness of the younger men to be misled by the I. W. W. (Industrial Workers of the World, a subversive organization that has succeeded the Western Federation of Miners in its rôle of trouble-maker), and disagreement between the miners and the operators as to the interpretation of the State eight-hour law. Back of these factors was the old fight of the operators for the principle of the 'open shop'. Mr. Power hinted at "the machinations of the Trust", meaning the Guggenheim smelter combination (the American Smelting & Refining Co.), as another evil influence, but for this he proffered no evidence. On the other hand, he attributed local ill feeling to the action of the owners of another mine because in the previous December they had shut-down their property for an announced period of 10 days, presumably for the Christmas holidays, and then continued the shut-down for months, much to the hardship of the men on the payroll.

The immediate issue was the claim of the miners that the shift should be measured from portal to portal, that is, the time spent in going from the portal of an adit, or other entrance of a mine to the place of work should be at the company's expense, not the miner's. For instance, on average it may take half an hour for a man, after arrival at a mine, to get to work and another half-hour to emerge from his place of work into daylight. At the Bunker Hill this loss of time is shared equally, so that the miner goes 'in' on his own time and comes 'out' on the company's. This seems fair. At the time of the strike no company was getting eight hours of work from its miners; indeed, as a matter of fact, not many of the managers knew exactly how much they were getting; in some mines the men were underground nearly ten hours and in others about nine. The lack of accurate data on the subject handicapped the representatives of most of the companies in their discussions with the Federal Mediator, whereas the manager of the Bunker Hill was able to show an accurate tabulation of the requisite figures. This grievance over time lost in going to work was the real cause of the strike, but it was followed by a demand for a blanket increase of 50 cents per day, despite the fact that an increase of 50 cents had been granted in the previous May and another increase of 50 cents on July 16; these increases had been made voluntarily by all the operators in the district in consequence of a sub-

stantial rise in the prices of lead and silver; they were not the result of any agitation or demand from the miners, they simply restored the rates obtaining prior to the cut of \$1 per shift that had been made in March 1919 when the bottom dropped out of the metal market. But wages was not the real issue, so these concessions did not prevent a strike, which began on August 15. The old demand for 'recognition', of Local No. 14 International Union of Mine, Mill, and Smelter Workers Union, was presented. On August 7 such employees of the Bunker Hill as were members of this union took a vote, but as a two-thirds majority in favor of striking was not obtained, they remained at work. Shortly before, the Wardner Industrial Union, to which 300 of this company's employees belonged, voted unanimously to continue at work.

At the Bunker Hill the miners go to work on their own time and come out on the company's time. They start to go in between 7:15 a.m. and 7:30 a.m. and are at their place of work by 8 o'clock. They have half an hour for 'lunch' at noon. They quit work at 4; the last man is 'out', that is, through the portal of the adit, at 4:25 p.m. The total time within the mine ranges from 8 hr. 15 min. to 9 hr. 10 min., which includes the half-hour for refreshment at noon. The time of actual working ranges from 6 hr. 50 min. to 7 hr. 22 min., as determined by careful records. This represents the so-called 8-hour shift. At the time of my visit the following wages were paid:

\$5.25 to miners
5.00 to shovelers and other common labor
5.75 to timber-men
6.25 to hoist-engineers
6.75 to shift-bosses

On February 16, 1920, in consequence of the improved metal market and the continued high cost of living, a voluntary increase of 50 cents per shift was made by the company to all its employees, and this higher rate of wages is still in effect. By way of comparison with the current scale, it may be stated that in 1896 the shift was 10 hours, the men arriving at 6:35 a.m. and leaving at 5:30 p.m., with an hour for 'lunch'; the pay was \$2.50 for laborers and \$3 for miners.

Nowadays when the men reach the mine in the morning they go to the change-house, where they doff their street clothes and put on their digging apparel. In the change-house they have chain-hangers, which are better than lockers. Dryers and shower-baths are provided, besides stationary wash-stands, and wash-tubs for cleaning clothes.

I saw the men coming from their work, tidy and clean, as against the dirty digging clothes in which formerly they returned home or to their boarding-houses, frequently not changing at all until going to bed. On August 5, 1919, the company issued 3000 circulars; for three days prior to the voting these were distributed not only among the employees but in the homes and business-houses of all the citizens of Kellogg, so that everyone in the community had a chance to read them before the ballot. This circular throws light upon the relations existing between the

company and its employees; therefore I give it in full herewith:

TO EMPLOYEES

Some of you are shortly to vote on a movement which may have very far reaching effects and if passed on unwisely will largely curtail the industries of this community and impose great inconveniences and hardships on many who are innocently involved and who are unable to assume such burdens.

That you may determine for yourselves as to what course you will take in this movement it is thought well to place before you certain facts which have a very direct bearing on this situation and which may assist you in choosing the course which you deem best for your own interests, for the interests of your family and friends and for the community.

The industries of this community have operated continuously without cessation of any kind for over twenty years and until war conditions affected such operations they were continually expanded and increased. At all times the work was carried to maximum capacity, at no time were men laid off because of metal market conditions, and in season and out of season, without regard to profits, metal markets, stock jobbing or any other motive the properties have been worked with full crews to the advantage of its employees and the community.

During these twenty years of operation there has been a continuous and steady improvement not only in working conditions and in wages and in hours of work, but also in the community itself and in the homes of the employees, because largely of the steady employment under good conditions and the never failing large payroll.

These improved working conditions and wages were not the result of any propaganda, coercion, or threats, but a natural improvement due to the growth, expansion and prosperity of the industry. Wages paid are now and always have been higher than in any lead mining district in the United States and that means in the world and are equalled or exceeded by very few other localities known of which do not equal Kellogg as a living and working community.

The last census of employees taken before the war showed an average period of employment of four years and ten months and many employees have continued steadily for over fifteen years and some for over twenty years indicating a stability unusual in the mining industry.

This same census showed 32% of employees to be owners of their own homes. This company on January 1, last, had 81 outstanding loans to its employees a total of \$46,723.85 to be repaid at the convenience of the borrowers at 6% annual interest to assist them in the purchase and building of homes. Three hundred and thirteen individual loans of this character have been made to employees in the past and in no case have forfeitures ever been taken. There are at the present time one hundred and forty eight leases on company ground to its employees and others at nominal rentals of about \$1.00 per year for home building sites.

Within the last few years there has grown up at Kellogg a modern city where formerly there were but stumps and brush. This city has been built and improved by money from the mining industries of this community; few, if any, citizens drew on outside capital. The company itself has reinvested many millions in new plant extensions, in modernizing old equipment, putting up of buildings, improvements of roads, side walks, all of which are of the greatest permanent value to all and whatever profits have been taken by the stockholders during this long period of years are from funds left after every local requirement had been fully satisfied. The

above facts are laid before you that you may know that the accomplishments in Kellogg could not arise from other than good conditions, socially, financially and industrially; individually owned homes, bank deposits, automobiles, fine schools and other public buildings with ample and continuous employment for all are evidences which cannot be destroyed by any critic. We can best judge of the future by the past and with the utmost confidence can we expect continued improvement in the coming years as has been experienced in the years past provided the industries are permitted to operate fully and efficiently.

The constructive growth of the past is not the result of any sudden change or upturning, but a natural progress and evolution continually towards better things and conditions. With these facts before you it is known that your best judgment will guide you in your vote and that you will not err in choosing what is best not only for yourself but for the other citizens of this city.

Sincerely,

BUNKER HILL & SULLIVAN M. & C. CO.

Kellogg, Idaho.

August 5, 1919.

The failure of the Bunker Hill men to join the strikers caused the strike to fail; it dragged along until October 8, 1919, when it was declared off. The steadfastness of the Bunker Hill men was due to the fact that the local union at Kellogg, which is recognized by the company, refused to play into the hands of the irresponsible elements at Wallace. Moreover, the fair and humane policy established by the management, under Messrs. Bradley and Easton, has won the loyalty of the men, as it deserves to do. When I was at Spokane last September, on my way from Kellogg to San Francisco, I was interviewed by the 'Spokane-Review' and said, *inter alia*:

"The strike in the Coeur d'Alene is petering out largely because the men working at the Bunker Hill & Sullivan are showing the goodwill that has been built up by years of fair treatment and humane consideration on the part of the management toward the men. It has become fashionable to talk about welfare work and to speak benevolently about the employer to the employees, but a lot of it is insincere, and the men are quick enough to detect the insincerity, wherefore it proves ineffective as a means of creating cordial relations. At the Bunker Hill, however, an experience of twenty years has convinced the men that the consideration shown by the manager and his staff is prompted not by commercial reasons but by genuine feelings of the kind that make democracy something more than a name."

Mr. Easton is a fine figure of a man; in physique and strength he is a natural leader of men, as well as in his mental qualities. Undoubtedly an essential manhood helps to establish the authority of a manager, and when to an impressive physique are added a generous heart and a clear head, the conditions are favorable to successful management. Mr. Bradley, as president of the company, makes semi-annual visits to the property. The townspeople invariably provide some excuse for meeting him in a public manner; on such occasions he gives a friendly talk to them, besides calling upon his old-time friends, thereby tightening the bonds of goodwill between the company and the town.

Another stalwart member of the company's organization is William McDougall, who has been superintendent of the mine since 1905. He began his mining at Grass Valley, California, and has worked his way up as shift-boss, foreman, and superintendent. Mr. McDougall has entire charge of all the underground operations of the Bunker Hill and its allied companies at Kellogg, and I am informed by Mr. Easton that he has been extraordinarily successful in handling the heavy ground of the large stopes and in modifying the practice to meet changing conditions, so as to extract the ore cheaply and

WILLIAM McDOUGALL, MINE SUPERINTENDENT

cleanly, but he has an unusually good record for the prevention of accidents. He is a member of the American Institute of Mining Engineers and one of the leading citizens of the community.

The character of those at the top gives the cue to the entire personnel. I noticed how courteous the members of the staff were to each other and how free apparently they were from the jangles that commonly spoil genuine co-operation. If one man asked another for information, he obtained it promptly and pleasantly, without the use, either facetiously or viciously, of loud talk or vulgar expletives, such as are only too freely used in mining districts. The members of the staff have been promoted from all kinds of lowly jobs. The manager himself went to work as a single-handed driller in November 1896. An office-boy has risen to the charge of the warehouse, a mine laborer is now chief engineer, the sampler is mill superin-

tendent, the assayer has held his present post 22 years, the cashier and office manager for 25 years. It may be suggested that there is too much in-breeding and that fresh importations might improve the stock. Dry rot is prevented by encouraging the departmental chiefs to travel and see the best practice elsewhere. Among the newest accessions to the staff is Emmett Waltman, who came back from the War with the Distinguished Service Cross, the Croix de Guerre, and the Belgian Military Cross. Before the War he was a shoveler in the mine; now he is in the survey department. He is a native of the Coeur d'Alene and won his Cross for building a foot-bridge across the Vesle while under fire. Another young soldier is Roy Hooper, who is in charge of prospecting work at the Alhambra mine of the Bunker Hill company. He was promoted to sergeant on the field of battle and suffered from shell-shock.

During the War the men were not lured away by the fanciful wages offered at the shipyards; they remained at Kellogg, where the conditions of living have been made comfortable for them. On the other hand, the company did not shut-down the mills and smelter whenever the prices of the metals (lead and silver) were so low as to justify either curtailment of output or complete cessation from production. They recognized their obligation to the community dependent upon their enterprise. The men who served in the War were re-employed as soon as they were demobilized, many of them being promoted on their return. The various services of the Government took 289 men from the company's payroll. The Honor Roll, of those who fell in battle, included 17. Their names are recorded here, for they surely constitute a part of 'The Bunker Hill Enterprise':

Lewis Newton Bailey	A. Glenn Nichols
Braxton Bigelow	Jacob Nybek
C. B. Bussell	Chester Robbins
E. N. Carroll	Hubert Everton Roberts
A. I. Hough	John Skala
Simon Iverson	George Sparenburg
I. N. Kemp	John B. Taylor
Arthur Gerald Leeson	Gus Zoellner
Roy Meyerhoff	

On the front wall of the company's office these names are inscribed upon a bronze tablet, with the following statement:

"These men, with two hundred and fifty-four others, left their work here to fight for the right in the great war of 1914-1918. This memorial is placed by their grateful friends and fellow-workers as a testimony to their sacrifice and service so gallantly and freely given that government of the people, by the people, for the people shall not perish from the earth."

Mr. and Mrs. Easton, of course, were at the head of all the war activities. Mrs. Easton was county chairman of the Red Cross, head of the War Insurance Board, and of the War Relief Work. Any woman in the community could come to her, not as the manager's wife, but as a woman, competent and sympathetic, and therefore able to give the most intelligent advice in matters personal as

well as public. On a cinema screen I saw the notice: "Keep up your war insurance; don't neglect your family and future. See Mrs. S. A. Easton."

The company is wise in not running a store of its own; it operates the light and water service; it established the water-supply for its own use, but allowed the town to connect with its system and use the water at \$2 per month per house, this rate being the one fixed by the State Board of Public Utilities. The company pays 60% of the school taxes, because its property is within the school district, but it never raised any objection to the erection of more schoolhouses. It may be said that the paving and lighting typify the pleasant relation between the town of Kellogg and the company, for the latter made itself responsible for the long stretch of well-paved and well-lighted avenue that extends from the bridge to the smelter.

The Bunker Hill property begins at the edge of the town, where the westward street crosses the flume. The concrete pillars of the bridge are surmounted with pieces of galena, which have been cemented in place. These pieces of ore have been chipped by boys, but enough remains to be symbolical. Along the flume near the bridge is a fence, where, I am told, "a bunch of Slavs" congregates regularly—let us hope to settle no questions nearer home than Fiume!

Among the foremen and shift-bosses are a number of Southerners, from the Carolinas and Tennessee. Most of them never saw a mine before they came to Idaho; they obtained their experience locally, but they are men of spirit and initiative, possessed of excellent judgment and always loyal. Others on the staff are Cornish and Welsh, men with mining traditions.

From the town through the Bunker Hill settlement and nearly to the smelter there extends a cement-paved highway flanked by handsome electroliers, which would do credit to any city. But this is a minor phase as compared with the houses and gardens that bespeak the comfort and thrift of the community. Beyond the mills is another cluster of houses, belonging to the smelter employees. Each house has six or eight rooms and is well equipped with modern conveniences. No two are alike; each has about an acre of ground, in which corn and potatoes are cultivated, also strawberries. Between the smelter and the mills I noticed one particularly attractive brick cottage; upon inquiry, I found that it belonged to Jim Sheridan, the chief bricklayer. When this house was built, the entire brick-laying crew worked on it gratuitously, out of goodwill to their leader, so that the building went up like a mushroom in the night. Jim Sheridan's home therefore serves as a monument to the kind of good feeling that has made the Bunker Hill something more than a hole in the ground.

The settlement as a whole, the company's part of it and the town of Kellogg, is more attractive than most mining 'camps', and above it rises ever the smoke of the smelter, like incense from the altar of industry—pace smoke-farmers and other disagreeable people!

When the town of Kellogg decided to establish a sewer system and found difficulty in getting money for the

purpose, the Bunker Hill company came forward and took the whole issue of bonds. To encourage education, the company gave a site, for the first schoolhouse, built it, and then deeded it to the district. The ground for the

course. Employees are encouraged to make homes for themselves. Land is leased to them at a nominal rate of \$1 per annum for any area less than an acre. Then the company lends money to build or to purchase a house at

THE HOUSE OF ONE OF THE COMPANY'S ELECTRICIANS

new schoolhouse likewise was provided by the company, on a 100-years lease. The Y. M. C. A. club-house was built and is owned by the company, which placed the

6%, although the local bank-rate ranges between 8% and 12%. The employee who borrows from the company pays monthly, with a diminution of interest as the capital

THE BUNKER HILL SMELTER

building in the town in order to increase its assessed valuation and to render it readily accessible to the townspeople.

The land around the mine belongs to the company, of

obligation is reduced thereby, so that the amount paid to the company is the equivalent of a fair rent. No instance of forfeiture or foreclosure is recorded. If a householder cannot pay, the loan is transferred to an-

other employee, who takes the property with the debt, the first party receiving his equity. Some of the men have been enabled to purchase property in fee simple in the town by means of financial assistance from the company. Sometimes, instead of borrowing money, the man goes to the company's warehouse and obtains the material—lumber, brick, and hardware—which is charged against him at 6% and paid off in the manner already indicated.

Employees are insured in accordance with the State law, which fixes a scale of compensation according to the nature of the injury. Under the Act the employer pays for this insurance. Every settlement is subject to supervision by the Industrial Accident Board of the State. Even before this law was passed, the company adjusted claims without recourse to the courts and without standing on the letter of its legal liability, that is, compensation was given for injury even when it was caused by culpable carelessness. The company does not carry compensation insurance with the State nor with any company; it compensates directly out of its own revenue, the sum set aside for this purpose representing a little less than $\frac{1}{3}$ of 1%, or 0.75%, of the payroll. The men pay \$1 per month and the company pays 50 cents per employee per month to the hospital. This entitles each employee not only to the treatment and care that the hospital affords but to the advice of specialists on ear, eye, nose, or throat diseases, as well as to orthopedic and other special treatment.

A big mine like the Bunker Hill serves as the nerve-centre for the surrounding region. As Mr. Easton said to me: "Lots of smaller activities hang to the coat-tails of a big mining enterprise like this." The miners accumulate a fund out of their wages during the winter and go prospecting in the summer. It must be confessed that this useful work is less popular than it was, so that many prefer to go on automobile excursions or to buy a farm. Members of the staff will take a share in a lease or small venture in the neighboring hills. The chiefs of the company or the company itself will employ members of the staff for investigations in regions far afield. While I was at Kellogg four young men returned from the Seward peninsula, in Alaska. They had been there four months, making an examination of a silver-lead prospect near Council.

We have reviewed the history of the discovery of the Bunker Hill & Sullivan group of mines; we have followed the course of the ore from the stope to the mill, from the mill to the smelter; we have watched the shipment of the refined metals to the markets of the world; we have traced the development of the enterprise from a small beginning to a big achievement; we have seen how it contributed to the growth of a model community and the impact of personal character upon human industry; it remains to suggest the influence of this mining enterprise upon the lives of men by recording a true story of one of its many thousand shareholders. When I was playing golf with a friend at Spokane on my return from Kellogg to San Francisco, my companion told me how many years ago he was in the office of a friend of his at Chicago. This friend, talking about the ups and downs

of life, remarked that when everything seemed to be going wrong with him he would turn about in his chair and look up at the photograph on the wall showing the Bunker Hill mine and would then recall the fact that it had seemed likely to fail at times, yet the stock he held in the enterprise had provided for the clothing, education, and helpful start in business of his children, and the reminder gave him a fresh impulse of courage to go ahead and a renewal of confidence in the future. Such a mine as the Bunker Hill is more than a hole in the ground; it is a splendid expression of hope, initiative, energy, and accomplishment; it is the fine flower of industrial achievement.

ROCK-DRILL steel is handled in the shop of the Champion Copper Co. as follows: The drills are received at the shop in iron baskets, those from each party of miners being ringed in separate bundles and each drill stamped with the serial number of the party. The baskets are lifted from the wagon or truck by an air-lift supported by an overhead trolley, and run onto the sorting platform. Here they are sorted and records taken showing the number returned by each party. Drills needing repairs are placed on a rack from which they go to the repair forges. The rest are placed on the rack at the heating-furnace, which is at present fired with coke, although one using oil with pyrometer control will be installed. The bits are heated to about 1900°F. the proper degree of heat being judged by color, and then go to the sharpeners. Incorporated on the sharpener is a quick-acting air-cylinder operating a long pin used to clear the hole in the steel, should this be found necessary. In sharpening, care is taken to pull out the corners that have become rounded from use. The device for doing this is a part of the fullering-die and consists of a pair of inclined planes set at an angle of 100°. Care is also taken that each operation in the sharpener is not carried too far. In other words, the bit receives a few blows from the fullering-die, then a few from the dolly; it then goes to the gauging-block, then back to the dolly or fullering-die, and so on, until the proper shape is obtained. After sharpening, the bit is tested by the gauging-ring and the drill placed on an inclined rack, which delivers it to the re-heating or hardening furnace. This was formerly a coke-furnace, but an oil-furnace with signaling pyrometer control is now used, affording an improved regulation of the heat. The importance of proper treatment of drill-steel has been emphasized more than ever by the results obtained in the all-around increase in efficiency.

A CONCESSION has been granted by the Venezuelan government to an American company for the construction of an electric railway from San Felix, on the Orinoco river, to the Guasipati goldfields of south-eastern Venezuela. The contract was signed on June 2 and is now being approved by the National Congress. The concessionaire has also made arrangements for the rental of water-power for generating hydro-electric energy from the falls of the Caroni river, situated about three miles from San Felix.

The Treatment of American Low-Grade Copper Ores

By An Australian

*The treatment of the low-grade copper deposits of the United States has as its main features high recoveries on ores containing in some cases under 5% of sulphides, high tonnages per unit-area of the mills in operation, and low working-costs. In a number of these orebodies the main mineral is chalcocite, a cuprous sulphide containing approximately 80% of copper. The principles involved in the treatment of these ores have a wide range of application, and should be of advantage in the concentration of Australian ores, although the latter are unlike in character. As this is a large subject, it can only be touched upon in a general way to demonstrate the main features of interest.

MILL CONSTRUCTION. Although timber construction in a mill allows more latitude for changes in flow-plan if the general scheme of concentration has not been finalized, once the best methods of treatment have been definitely ascertained, concrete and steel construction is greatly to be preferred from an operating standpoint. For this reason, although large-scale experimental plants are usually built of timber, the final construction of most of the large American mills is of steel or concrete. The advantage of this is shown among other things in the very smooth running of all types of machinery in mills of this class. In spite of the very heavy tonnages put through, mechanical break-downs are of rare occurrence. A feature of their design also is the arrangement of launders in concrete tunnels beneath the concentration floors, which allows of a cleaner and better type of mill construction.

COARSE CRUSHING. In most American mills dry crushing by rolls is carried to a further stage than is the case in Australia, the ore being crushed dry as fine as $\frac{1}{4}$ inch in some cases. The usual practice in large-tonnage mills is to crush initially in huge gyratory breakers of very large capacity with the usual type of grizzly at their head. At the Utah Copper Company, for instance, a single gyratory crusher is installed which will crush 1000 tons per hour with ease, large trucks of ore being dumped bodily onto the grizzly above the breaker. The ore is initially crushed to approximately 3 in., the remainder of the reduction being usually performed by rolls. The type of roll in common use differs from that used in Australia. High-speed rolls, belt-driven, with steel springs, are almost universally used. Series crushing is generally practised, the ore being usually crushed in two stages from $2\frac{1}{2}$ to 3 in. mesh down to $\frac{3}{4}$ inch. Each pair of rolls is set at a definite aperture, there being no oversize return, and their crushing capacity at these coarse sizes is very high. Thus four pairs of 60-in. rolls, working two pairs in series

with the other two, assisted by screens at the head of each system, will on an ore of medium hardness crush approximately 6000 tons per day under the conditions referred to above. Rotating screens are largely in use, but in this respect the Mitchell screen is a noteworthy metallurgical improvement. It is made to vibrate by a motor giving 3500 vibrations per minute. The movement of the screen itself is so small that when seeing it in use, it is difficult to realize that it is working at all, although the quiver can be distinctly felt by the hand. The efficiency is high and the construction simple. The advantages are so marked that one has only to see the screen in operation to be convinced of its merit, and it seems a matter of a short time only before other types will be displaced by it. The use of elevators between different sets of rolls is ingeniously overcome by the use of conveyors at the Utah Copper Co.'s mill, where the Mitchell screen was first developed in practice.

In considering the advantages of crushing dry to $\frac{1}{4}$ inch and under, by rolls, the fact must be taken into consideration that most of the low-grade copper-ore deposits have the copper sulphides finely disseminated in the rock and require initial fine-crushing to free the recoverable mineral. With a feed dry-crushed in this way it can be more readily handled in the later stages of treatment. In the case of some ores dusting would be a great disadvantage, and where very coarse mineral can be recovered, as at Wallaroo,† by a jigging operation, it is doubtful if the advantages would be so marked. Each ore has its own grinding problems, but on American low-grade copper ores rolls have been a marked success used in series on coarse-crushing, the costs being low and mechanical troubles few. When followed by a 'one-step reduction', as it is termed, the extreme practice being at the Inspiration where the ore is crushed in ball-mills from 2-in. size to approximately 2 or 3% on 48-mesh in one operation, dry crushing has very marked advantages over any other system.

This is usually carried on till the ore is crushed to $\frac{3}{4}$ in. or $\frac{1}{2}$ in. size. A dry feed of this nature can be stored conveniently in intermediate bins, making the fine-crushing and concentration sections independent of stoppages of the coarse-crushing plant. At $\frac{3}{4}$ -in. size also it lends itself to accurate sampling and a convenient site for a sample-mill is between the coarse and fine systems. The main advantage is absolute control of tonnage to the concentrator, and accurate adjustment of water to ore in the ball-mills, a requirement essential to the highest crushing efficiency that can be readily maintained. The disadvantage of the system is dust, but in most ores there is sufficient moisture to check this, to a large extent, pro-

*From 'Chemical Engineering and Mining Review', Melbourne, August 5, 1920.

†In South Australia.—Editor.

vided dry-crushing is not carried to too great a degree of fineness.

FINE-CRUSHING SYSTEMS. From the fine-feed bins the supply of ore is usually controlled by a feeder of the Challenge type, the best method being to sectionalize the concentration department into 1000-ton per day units, each unit being provided with a feeder delivering onto a conveyor on which the fine ore is automatically weighed by a Merrick weight-meter. In a large-tonnage unit the control of feed at this point is vital in importance, as irregularities here will have a disturbing effect on the metallurgical results of the whole section, whether wet concentration or flotation is in use. A knowledge of the rate of feed at all times permits of a reduction of oil or reagents in flotation to the smallest limits, while an excellent control of conditions is possible.

BALL-MILLS. Ball-mills of the best types have come to stay. Judging by the smooth running of these machines in the Miami and Inspiration mills one can say with certainty that from a mechanical standpoint practically all troubles have been eliminated, and a ball-mill of good type, if placed on sound foundations, will certainly run as well as an ordinary pebble-mill. The best practice, especially in primary-flotation systems, is to have ball-mills in closed circuit with Dorr classifiers. With this combination a very close control of crushing is possible, resulting in a more even grade of crushing than is usually the case if the ball-mill alone is used. Both the Marcy and Hardinge ball-mills are greatly in favor at present, the latter having the advantage that it can be re-lined in place and has no screens in front to wear. The cost per ton of crushing with both mills is approximately the same. The shape of the Hardinge mill allows for a very compact motor-drive. It is well designed, and its reliability from a running standpoint alone would account for its large use in America.

MILLING AND FLOTATION PRACTICE. The tendency in the treatment of copper ores is more and more toward simplicity. The question of concentration before or after flotation has to be considered carefully in the case of each ore under investigation. Owing to the low first-cost of plant and great simplicity of the one-step reduction system followed by primary flotation, it is very doubtful if the adoption of primary concentration purely for the use of obtaining a more granular product and one more suitable for smelting than the concentrate produced by flotation is justified on an ore unless it is very coarse in texture.

Not only does primary concentration result in greatly increased cost of plant-equipment, especially at the present time, but thickening devices are necessary between the concentration and flotation plants to de-water the feed for flotation. More labor is required and the cost of treatment is higher. A few years ago lack of faith in the results likely to be obtained by flotation resulted in the erection of a primary or secondary concentration plant from a point of view of safeguarding recoveries. That time, however, has passed. The original design of a concentration plant is dependent to some extent on smelting conditions, particularly as regards the iron contents of

the ore, whether the iron pyrite present in it floats or not, and whether iron is required for smelting or a high-grade copper concentrate low in iron is preferred. In some cases also primary concentration is used in the case of low-grade ores to reject a low-grade tailing and save the cost of crushing and flotation on a product below the payable limit as far as values are concerned. This is the practice of the Utah Copper Company.

Schemes at present in use embodying concentration and flotation are:

- (a) Primary concentration followed by flotation.
- (b) Primary concentration followed by flotation and secondary concentration.
- (c) Primary flotation followed by concentration.
- (d) Primary flotation followed by concentration and secondary flotation.
- (e) Flotation alone.

The general tendency is toward the adoption of flotation alone, using the one-step grinding system. Wet concentration, using tables to treat the sandy portion of the flotation tailing, which is de-slimed by Drag classifiers or Dorr bowl-classifiers, results in a much simpler plant than where primary concentration is practised. No de-watering systems are necessary, and the concentration plant recovers the coarse mineral lost by flotation. This is the system practised at the Inspiration, and the factors leading to the adoption of this flow-sheet are ably summarized in the excellent paper read by Dr. Gahl in 1916 before the American Institute of Mining Engineers. Most chalcopyrite ores are particularly adapted to the simple flow-sheet of one-step grinding and primary flotation, a common practice in America being to add oil to the ball-mill and float the crushed product in Callow cells.

The main feature of water concentration on these ores is that classification is carried out to a greater extent than is usual in Australia. With an ore which in crushing produces a slime difficult to settle, experience has shown that it is essential to make a clean separation of sand and slime to get the best results by water concentration. The Deister tables are very much in favor, owing to their smooth running. The plateau effect also has marked advantages where a clean separation is desired. To economize floor-space double-deck machines have been found satisfactory. A feature of modern tables is the self-oiling head-motions, which not only ensure smooth running, but reduce repairs and attendance costs to the minimum.

As far as flotation is concerned, the bulk of the flotation problems on these ores has been solved, and the control is becoming more simple. On some properties successful results are being obtained using over 1% of oil on the ore treated. Flotation methods, however, will not be completely finalized till the cloud of litigation has passed away.

TREATMENT OF CARBONATE AND OXIDIZED ORES. Before closing this paper a brief mention of the treatment of these ores may be of interest. Although there is no great difficulty in the flotation of carbonates by using sodium or hydrogen sulphides and thereby probably creating an artificial sulphide film on the faces of the carbonates, the trouble with most of the oxidized copper ores lies in the

fact that there are large amounts of copper, in the form of silicate, that cannot be floated in this way. In many cases there is a greater percentage of silicate than carbonate. The recent success of solution with sulphuric acid and electrolytic precipitation at Ajo has proved that this system of treatment is highly profitable, and there is little doubt that on certain ores there will be a further application of this method in the near future. For a mixed oxidized and sulphide ore the leaching of the oxidized portion first by sulphuric acid leaves the sulphides in the residue in an ideal condition for flotation, and it is probable that treatment methods will evolve along these lines.

Pumping in the Rand Mines

The impending exhaustion of many of the shallower mines on the Rand will throw a burden of increased pumping on the neighboring mines whose workings have reached lower levels. Few mines are likely to feel the effect of the cessation of pumping in the old ventures nearer the surface as much as the Village Deep, which has the old workings of the Salisbury, Jubilee, and Wemmer to its north and the declining Village Main, City and Suburban, and Ferreira Deep impinging on its boundaries. The City and Suburban may be absorbed by the City Deep and this latter company will therefore presumably be responsible for pumping arrangements in the City and Suburban. All the same it is clear that the City Deep, Village Deep, Robinson Deep, and other deep-level properties of the central section of the Rand will have to make adequate arrangements to deal with any influx of water which may find its way into their workings through the older mines which immediately adjoin the town of Johannesburg to the south. With this object in view, the design, cost, capacity, and location of a large central Rand pumping-plant is now receiving attention. Extensive work in connection with underground dams and walls is in progress at several properties in the central section of the fields. The Rand cannot be regarded as one of the wettest of the world's mining fields, but at certain periods heavy floods have drowned out the lower levels of numerous properties and the pumping-plants of individual companies have been unable to cope with the influx.

The mines, as a rule, have only sufficient pumping equipment to cope with the normal requirements. If an increased inflow is anticipated, additional arrangements are made. Consequently, if an abnormal flood occurs the lower workings of a mine are in danger of being filled more rapidly than the pumps can deal with the water, pumps are lost, the water rises in the workings, and the engines and skips have to be used for bailing water instead of hoisting rock, so that routine operations are sometimes brought to a complete standstill. Nearly every mine in the Johannesburg district suffered severely from the unusual heavy rains in February 1918, this abnormal fall coming at a time when many of the mines

were already having great difficulty in coping with the water from the previous heavy rains in the latter part of 1917, and so completely overtaxed the existing pumping plants that the lower levels were flooded, and work there was suspended for some time.

The position at the Crown Mines South Rand (No. 5) shaft at this time is worth recording. The pumping plant at the main station on the 13th level, consisting of four Sulzer centrifugal pumps, of which two were intended as reserve, worked 90% of full time over a period of four weeks, handling 3,800,000 gal. per day; in addition to this, bailing had to be done both by skips and 2000-gal. bailers, the total volume of water handled per day amounting to 4,460,000 gal. The New Heriot mine on February 14 was only saved from disaster by the foresight in having had a reinforced concrete culvert constructed over the outcrop about 18 months before. This culvert was built inside an old culvert resting on the outcrop pillar, 50 ft. deep, and was carried on steel ropes extending a considerable distance north and south of the outcrop. On the principle that prevention is better than cure, the mines of the Central section are now considering co-operative arrangements which should ensure them against serious difficulties with water in the future.

AN EXAMINATION of the available, and in most instances official, sources of information for the principal coal-mining countries shows that the largest production per man during any year was 1134 short tons, the average production for each underground employee in the coal mines of the United States during 1918. The closest competitor of this country was New South Wales where each underground worker in 1918 produced 814 tons. British Columbia ranked third with 790 tons and Nova Scotia was fourth with 718 tons. The smallest individual output for recent years was that of Japan in 1917, where an average of 155 tons was mined by the underground employees, although in 1901 India showed an average of only 122 tons, the latter figure being the smallest during any year for the countries under consideration. During the 18-year period New South Wales and Nova Scotia have each averaged practically the same amount (718 and 715 tons, respectively). The individual output for Great Britain was until 1910 above that of Prussia, but in 1911 Prussia passed the British record and has maintained the lead since that time. France has shown but little change in the miner's yearly production, averaging 302 tons prior to the War. In Austria the annual output has averaged 296 tons per man during the past 18 years. Following Austria comes Belgium with an average of 236 tons during the 18-year period. The man-production in Belgium remained around 250 tons until 1914, when it dropped to 200 tons and showed only a slight increase during the five years of the World War. The underground workers of India have shown an almost steady increase in annual output, the quantity having risen from 122 tons in 1901 to 203 tons in 1918, averaging 178 tons during the entire period. In Japan the average output over a 17-year period was 174 tons.

Recovery Formulae

By HALLET R. ROBBINS

All ore-dressing metallurgists are familiar with the useful formulae originally derived by Jesse Seobey, for determining the indicated percentage of recovery and ratio of concentration, from the assay of the feed, concentrate, and tailing, without requiring a knowledge of the actual or relative weights of these products. These formulae are applicable to the case in which one concentrate only is made, and I do not recall having seen any similar formulae covering cases in which two or three concentrates are made. I have derived such formulae for my own use, and offer them herewith for the convenience of others.

Let

Ho	=	Assay of heads or feed in metal	O
Hp	=	" " " " " "	P
Hq	=	" " " " " "	Q
COo	=	" " O concentrate	O
COp	=	" " " " " "	P
COq	=	" " " " " "	Q
CPo	=	" " P " " "	O
CPp	=	" " " " " "	P
CPq	=	" " " " " "	Q
CQo	=	" " Q " " "	O
CQp	=	" " " " " "	P
CQq	=	" " " " " "	Q
To	=	" " tailing	O
Tp	=	" " " " " "	P
Tq	=	" " " " " "	Q
EO	=	Proportion of metal O recovered in	O concentrate
Ep	=	" " " " P " " "	P " "
Eq	=	" " " " Q " " "	Q " "
Ro	=	Number tons ore to yield one ton	O concentrate
Rp	=	" " " " " " " "	P " "
Rq	=	" " " " " " " "	Q " "

Then in case a single metal is saved in a single concentrate (Seobey's formulae)

$$EO = \frac{COO (Ho - To)}{Ho (COO - To)}$$

$$Ro = \frac{COO - To}{Ho - To}$$

Where two concentrates are made, for the recovery of metals O and P respectively

$$EO = \frac{COO}{Ho} \times \frac{(Ho - To) (CPp - Tp) - (Hp - Pp) (COp - To)}{(COO - To) (CPp - Tp) - (COp - Tp) (CPo - To)}$$

$$Ro = \frac{COO}{HoEO}$$

$$Ep = \frac{CPp}{Hp} \times \frac{(Hp - Tp) (COO - To) - (Ho - To) (COp - Tp)}{(CPp - Tp) (COO - To) - (CPo - To) (COp - Tp)}$$

$$Rp = \frac{CPp}{HpEp}$$

Where three concentrates are made, for the recovery of metals O, P, and Q respectively

$$EO = \frac{COO}{Ho} \times \frac{(Ho - To) (CQp - Tp) - (Hp - Tp) (CQo - To)}{(COO - To) (CQp - Tp) - (COp - Tp) (CQo - To)}$$

$$EO = \frac{COO}{Ho} \times \frac{(Ho - To) (CQq - Tq) - (Hq - Tq) (CQo - To)}{(COO - To) (CQq - Tq) - (COq - Tq) (CQo - To)}$$

$$Ro = \frac{COO}{HoEO}$$

$$Ep = \frac{CPp}{Hp} \times \frac{(Ho - To) (CQp - Tp) - (Hp - Tp) (CQo - To)}{(CPo - To) (CQo - To) - (CPp - Tp) (CQo - To)}$$

$$Ep = \frac{CPp}{Hp} \times \frac{(Ho - To) (CQq - Tq) - (Hq - Tq) (CQo - To)}{(COp - To) (CQq - Tq) - (CPq - Tq) (CQo - To)}$$

$$Rp = \frac{CPp}{HpEp}$$

$$Eq = \frac{CQq}{Hq} \times \frac{(Ho - To) (CPq - Tp) - (Hp - Tp) (COp - To)}{(CQo - To) (CPp - Tp) - (CQp - Tp) (COp - To)}$$

$$Eq = \frac{CQq}{Hq} \times \frac{(Hp - Tp) (CPq - Tq) - (Hq - Tq) (CPp - Tp)}{(CQp - Tp) (CPq - Tq) - (CQq - Tq) (CPp - Tp)}$$

$$Rq = \frac{CQq}{HqEq}$$

For a two-concentrate example of the application of the preceding formulae, the data given on page 1830, Vol. IV, of Richards' 'Ore Dressing' may be taken. These data refer to results of operations at the Lebanon plant of the Pennsylvania Steel Co. Making the proper substitutions in the formulae, the indicated recovery of the copper in the copper concentrate is 57.9% and the ratio of concentration 23.2:1; the indicated recovery of the iron in the iron concentrate is 87.5% and the ratio of concentration 1.54:1.

For a three-concentrate example, reference is made to page 923, Vol. LII, Transactions American Institute of Mining Engineers, where analyses are given of the several products obtained in the operation of the concentrator of the Timber Butte Milling Co. There are really four concentrates given in the reference cited, but making a weighted average of the coarse and fine zinc concentrates and called that a zinc concentrate, and making the proper substitutions in the formulae, the indicated recovery of copper in the copper concentrate is 4.45%, and the ratio of concentration 69.3:1. The indicated recovery of the lead in the lead concentrate is 22.1% and the ratio of concentration 305:1. The indicated recovery of zinc in the zinc concentrate is 80% and the ratio of concentration 3.46:1.

A comparison of indicated and actual percentages of recovery and ratios of concentration will often call attention to leaks, slops, and other mechanical losses of concentrates that otherwise might escape notice.

A DEPOSIT of magnesite that crops out on a steep hillside west of Ash creek, two miles above its junction with Gila river, about 30 miles north of Lordsburg, New Mexico, was recently examined by R. W. Stone, of the U. S. Geological Survey. The general alignment of the outcrops might indicate that it is a continuous body, 1000 to 1500 ft. long and 30 ft. thick, in limestone, but close examination shows that the limestone occurs as a number of detached blocks, none of them more than a few rods long, enclosed in granite and cut by dikes and sills of diabase older than the granite. The magnesite has replaced certain beds of limestone, but at no place has it yet proved to be 30 ft. thick, as at first indicated. At one place where the deposit has been prospected and has since caved there appears to be a total thickness of 20 to 30 ft. of magnesite and limestone. The best exposure shows only 7 ft. of magnesite in a limestone block 5 or 6 rods long, in which the beds stand vertical. The magnesite is hard, amorphous, and pure white, resembling the variety common in California.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NEW EQUIPMENT AT THE IRON CAP AND ARIZONA COMMERCIAL.

BISBEE.—Work has commenced by the Calumet & Arizona Mining Co., on the Junction shaft, which is to be sunk approximately 500 ft. from the 1800-ft. level. It is reported that considerable water has been encountered and in the shaft alone the flow has increased from 20 inches daily to 100 inches.

Changes are being effected in the power plant; six boilers are being replaced and two additional ones added. Stacks for the new boilers will be erected shortly. It is presumed that this increase in power will be sufficient to care for all the needs of the shaft.

Work will shortly be completed on the new ventilating shaft for the Briggs division of the C. & A. mine. This shaft will provide an outlet to the surface for the smoke and gases arising from a possible outbreak of the fire in the large sulphide orebody in this division. It will be necessary to drift approximately 50 ft. from the bottom of the ventilating shaft in order to connect with the mine workings.

The Shattuck-Arizona Copper Co. has filed a petition with the State Corporation Commission seeking relief from alleged excessive switching charges. The El Paso & Southwestern Railroad Co. is named as the collector of the charges.

The output of the Shattuck-Arizona for August is given as 194,003 lb. of copper, 463,552 lb. of lead, 34,661 oz. of silver, and 406 oz. of gold.

MOHAVE DISTRICT.—Advices state that the shaft on the McCracken property at Kingman, has reached a depth of 620 ft., 220 ft. below the old level.

The United Eastern and Tom Reed mines, Oatman, are said to be operating at two-thirds capacity, all exploration work having been postponed until cool weather.

MARICOPA COUNTY.—It is reported that the old Vulture mine, 16 miles south of Wickenburg, is to be dismantled. The property has been idle for some time. During 1915 it produced 29,968 tons of gold-bearing ore, but no recent financial statement has been made.

GREENLEE COUNTY.—The Duncan Mining & Milling Co. is said to have recently found good orebodies in its development work. This company maintains its head office at Duncan, Arizona, but the mines are situated in the Steeplerock mining district of New Mexico, just across the Arizona state line. The owners of the New Year's Gift group of mines in the same district are planning the erection of a 100-ton mill.

GLOBE-MIAMI DISTRICT.—The Gibson Consolidated is reported to be working 18 men. Drifting on the 300-ft. level continues and low-grade ore-reserves are being steadily blocked out for future milling.

Construction work on the new crushing plant for the Miami Copper Co., adjoining its new No. 5 shaft, is progressing rapidly. The work will comprise 3200 yards of concrete, and it is the intention to complete it within the next few months.

A request for an increase in wages of \$1 per day was recently made by the employees of the Miami Copper Co. and Inspiration Consolidated Copper Co. The demand of the employees was based on the claim that the cost of living had advanced from 80 to 150%. The request was denied on the ground that "the very adverse conditions existing at the present time in the copper industry make it impossible to consider an increase in the wage scale".

Inspiration Consolidated Copper Co.'s August output was 7,200,000 lb. against 6,500,000 lb. in July.

The Iron Cap Copper Co. is equipping its Iron Cap shaft with a complete system of fire protection. This consists of fire-doors, placed near the shaft-stations on every level, which, upon being closed, immediately isolate the shaft from the mine workings. In addition to this, water lines are placed in the shaft with sprays at regular intervals in each of the three compartments. The sprays are regulated by valves placed at the point of connection with the main water line, which is controlled by a valve on the surface, near the collar of the shaft. The fire doors at the shaft-stations are controlled by a separate compressed-air line. A small cylinder is attached to this air-line at each door and holds the door open. When an emergency arises the air in the cylinders is released by turning off the compressed air and opening the release-valve on surface. This allows the doors to close immediately. As soon as the doors are closed, the water valve is turned on and the sprays in the shaft begin to operate, thus providing an even distribution of water throughout the shaft. Should a fire occur in the shaft, the doors are immediately closed and when water is turned into the shaft it will be impossible for the smoke and gases to find their way into the mine workings and thus endanger the lives of the men.

The steel connections for the conveyor-belt which will transfer the ore from the skips of the new No. 2 shaft of the Arizona Commercial Mining Co. to the ore-bins, which have been built on the hillside some 40 ft. below the collar of the shaft, are now in place and the ore-bins are

complete. The grading of the railroad-spur is also being finished. In the course of time a number of buildings, such as timber-sheds, change-rooms, etc., will probably be erected near the new No. 2 shaft and it is believed that eventually No. 2 shaft will be the main operating shaft of the property.

PINAL COUNTY.—The Dripping Springs Copper Co., situated in the Old Flat mining district, near Winkelman, is preparing for active production and development work. The company has recently purchased the machinery and equipment of the Ray Broken Hill property, and has erected bins both at the mine and at Christmas, the shipping point. Regular shipments of ore have also been commenced.

The orebodies are on lime-diabase contacts enriched where they are intersected by the veins coming through the limestone. The two most important veins are the D and E vein. The D vein was found in the early part of this year, but it is only during the past month that the E vein has been intersected by the lower cross-cut tunnel. The total width of the D vein is reported to be 42 ft., the assays varying from 4.7 to 10% copper. The E vein was cut 520 ft. beyond and while it has not yet been explored, it is reported to show a width of about 14 ft. and contains both native copper and oxides.

NOGALES.—It is reported that the Labor Bureaus of the States of Colima, Jalisco, Nayarit (formerly Tepic), Sinaloa, and Sonora will shortly make a demand that American companies agree to defray the expenses of Mexican contract laborers from their homes in Mexico to the scene of their labor in the United States and return. According to labor statistics 23,000 laborers are wanted from the West Coast States of Mexico, by the sugar-beet, cotton, and other industries in the United States this year. In permitting these 23,000 Mexicans to enter the United States for the above purposes, the Sonoran government would, under previously prevailing conditions, assume the responsibility of returning them to their homes. If all returned to the border with insufficient money to defray their expenses back into Mexico, as between 85 and 90% are reported to have done last year, it would cost the Government approximately \$26 each, or \$299,000 in American money. This form of Mexican contract labor may possibly mitigate the labor shortage when the mines in Arizona again resume full production.

HAYDEN.—At a meeting in New York on September 10, the directors of the Ray Consolidated Copper Co. declared a quarterly dividend of 25c. per share, payable on September 30. This will total \$394,294.75, and bring the total dividend disbursements up to \$25,028,335.92.

COLORADO

RECENT APPOINTMENTS AT GOLDEN.

CRIPPLE CREEK.—A new vein has been found in the Cresson mine 700 ft. west from the shaft at the 1600-ft. level. The vein is narrow but rich ore is reported and it is being explored. Lessees on the Damon group, United Gold Mines Co., Ironclad hill, continue to mine a high-grade ore from shallow workings. Settlement on

the last car was made on a basis of \$135 per ton for a 30-ton lot. Upper levels of the Jerry Johnson mine adjoining the Damon have been taken under lease by local men who are searching for a continuation of the ore on that property. Drilling at the formation test in the north-east end of the district has been delayed by the drill's fitchering. The driller is fishing and is confident that he will recover his tools.

August production of the Cripple Creek district as reported from the mills and by the district representative of the American Smelting & Refining Co. totaled 36,991 tons with an average value of \$12 per ton and gross bullion value of \$477,603. Of this tonnage the Golden Cycle mill at Colorado Springs handled 18,000 tons of one-ounce ore, valued at \$363,000; the Independence mill of the Portland Gold Mining Co. near Victor, 18,291 tons, valued at \$62,104; and the Smelter at Pueblo, 700 tons, valued at \$52,500.

LEADVILLE.—Lessees in the Dinero tunnel continue shipments of high-grade silver ore, assaying from 100 to 150 oz. per ton. John Cortellini, chairman of the Bureau of Mines and Commerce, leasing on the Garbutt, has resumed operations. The mine has been idle since the walk-out of miners some weeks ago. The Blaine on Yankee hill continues production of zinc ore at a rate of about 20 tons daily, that averages 25% zinc. A new plant has been erected on the Ponsardin to replace machinery destroyed by fire, and production has been resumed. A shortage of ore-haulers in the district is causing accumulation of tonnage at many leased properties.

BOULDER.—Increased forces are working on the Caribou and other properties and the output for the month will show considerable increase. The White Raven is shipping steadily and plans to continue operations through the winter. The Yellow Pine, under lease to E. B. Hill and Boulder associates, is active. The lessees are sinking 900 ft. J. W. Pherson, another Yellow Pine lessee, is producing and shipping a good grade of ore. The new mill at the Blue Bird is nearing completion. Ore-reserves are being developed for the mill. The Boulder sampler is operating at capacity.

KOKOMO.—A permanent camp has been established at the Pearl group and supplies sent in to keep the mine in operation during the winter have been sent forward from Denver by the Kokomo Mining Co. for use at the Chalk Mountain property.

TELLURIDE.—August shipments from the Telluride mills were 60 cars from the Tomboy and 35 cars from the Smuggler mines of the Smuggler-Union. Progress is being made on the construction of the new plant at the Smuggler.

DENVER.—The Board of Trustees of the State School of Mines at Golden have appointed Harold W. Gardner, of the University of Illinois, professor of civil engineering; G. W. Gorel, a graduate of Wesleyan, professor of mathematics; W. P. Hale, formerly head of the department of mathematics at Broadus College, West Virginia, assistant professor of mathematics; L. D. Roberts, assistant professor of chemistry.

MICHIGAN

REDUCED COPPER STOCKS.

CALUMET.—Calumet & Hecla has completed shipment of the 2200 tons of copper ordered by French concerns several months ago, the final shipment consisting of 2,400,000 lb. The entire order called for wire-bars and billets, all special shapes that required additional time. This practically completes the unfilled orders at the Calumet smelters and for some time, perhaps thirty days, metal will accumulate on the docks. A small shipment of 100,000 lb. went to Detroit last week from the Calumet docks. This is one of the new orders booked by C. & H. for the Michigan metropolis this year. Calumet's Detroit business for twelve months, in fact since the Armistice was signed, has been negligible compared with war orders and even less than pre-war sales. Calumet's surplus on the Hubbell docks and in process of refining aggregates

August against 10,125 in July. This reflects the recent transfer of 25 men to the Calumet Osceola shafts. Kearsarge dropped slightly in August, with a 'rock' tonnage of 39,572 against 40,715 in July. Allouez cleaned up the remainder of the 'rock' that was broken down in the stopes when the mine suspended, and its shipments for August aggregated 1000 tons. Superior reports 1520 tons for August, an increase of 400 tons over July. There were no overflow shipments from Isle Royale, the production being barely sufficient to keep its own mill in operation.

Calumet & Hecla is using a stope-scraper to advantage and there is a likelihood that more of the same type will be introduced. The scrapers are in use on the 75th level of No. 7 shaft and also in No. 10 and in the Red Jacket shafts. Operated by three men, the scraper handles 40 cars of rock on a shift, against nine or ten cars filled by

GOLD HILL, UTAH

7,000,000 lb. and there is still close to 13,000,000 lb. of refined copper on the docks of the old Tamarack-Osceola smelter at Dollar Bay. The total, 20,000,000 lb., reflects a material improvement in the metal situation since the first of the year when Calumet & Hecla alone reported upward of 32,000,000 lb. on hand. The surplus at the Calumet docks represents the metal on hand of all subsidiaries as well as the parent company so large reductions in the stocks of all companies have occurred. Smelter-men, whose observations of conditions invariably serve as a barometer of the metal trade, are optimistic in their views of the immediate future and they forecast a material improvement early in October. The fact that Calumet's smelters are operating at capacity, with all furnaces in commission, seems to bear out this prediction and there is a better feeling in evidence throughout the Lake district.

'Rock' tonnages for the Calumet mines for August show small changes, compared with July, save for Ahmeek which shows an improvement. During the month, Ahmeek reported approximately 71,350 tons against 68,068 in the preceding month. The old Osceola shows a decrease of about 2800 tons, reporting 8100 for

hand-tramming by two men during the same length of time. The unusual performance of 40 cars on a shift for the scraper comes only in cutting out the stopes. The mechanical 'mucker' in use in the haulage tunnel is an assured success for, operated by four men, it fills from 16 to 18 cars on a shift, or as much as eight men could fill by hand shoveling.

The Tamarack and North Tamarack reservoirs are being drained in the hope of reducing the flow of water into the mines. Both contain a large amount of water and it is likely that much of the surface water that seeps into the lower workings comes from them.

The old Tamarack mill is practically dismantled and about 50% of the equipment has been moved from the site. The razing of the plant is proceeding at a rate that indicates it will be possible to begin work on the reclamation-plant foundations before early winter and steel erection can be commenced in the spring. Under favorable conditions it should be possible to turn out mineral by the early part of 1922.

Wolverine is installing an electric pump at the old Wolverine mill dam which was in use when the stamping plant was built near the mine. The water has been

seeping down into the mine, adding to the difficulty of keeping the mine free from water. With this flow cared for, Wolverine will have to pump only its normal accumulation of water and both shafts will be permanently free for 'rock'-hoisting continually. Considerable interest has been aroused locally over the plan of Wolverine to develop additional lodes on the 28th and 13th levels and there is a hope that valuable ground will be opened. The section on the 28th level is in the foot-wall and the 13th involves explorations in the hanging. Several veins penetrated in cross-cutting the property have shown up well and while the openings were not rich in copper there was sufficient mineralization to warrant extensive developments before giving up the mine. The 13th-level objective is the Kearsarge conglomerate, of which comparatively little is known from developments in late years but the old Ahmeek found this lode exceedingly rich. It is this vein that Seneca tapped by a diamond-drill last spring, but in the section from which the cores were taken the mineralization was somewhat disappointing. Seneca's disclosures, however, by no means indicate that there is no copper in the vein elsewhere. Both Wolverine and Mohawk are producing about 70% of normal, with the former hoisting from 800 to 900 tons per day and Mohawk, 1400 to 1700 tons. Wolverine's yield for the past few months has been in the neighborhood of 17 lb. while Mohawk holds persistently to 23 lb. to the ton. Wolverine 'rock' still is being stamped in the Mohawk mill and this arrangement likely will continue until greater output is required. The concentration of operations in the one mill makes for a marked saving of fuel and at the same time affords opportunity to make necessary changes and repairs in the Wolverine mill. The new pumping plant, owned jointly by the two companies, is operating successfully and economically. It means a considerable saving in fuel, because it is operated by exhaust steam that has hitherto been wasted. The project will have paid for itself within a few years even on a reduced operating basis. Considerable power can be generated by the turbine in excess of present needs and this will be utilized later by the re-grinding units which it is proposed to install when conditions justify additional expenditures. Both Mohawk and Wolverine are well sold up and there is little of any metal on hand. Chicago, Detroit, Kenosha, and other cities are consuming Stanton copper readily, so these mines are free from the worry of carrying over large stocks. Approximately 30% of the normal supply of coal has been received by Wolverine and Mohawk, although on the present operating basis not more than 50,000 tons will be needed by both plants for the winter.

Seneca reports a material improvement in the third level, north, at a point 816 ft. from the shaft, while good ore is still found in the fourth, 558 ft. from the shaft. In the south drift of the fourth level progress has been retarded because of the labor shortage and it will be some time before the Ahmeek boundary is reached. Altogether, Seneca is operating eight machines, two of which are used in sinking and the remainder are in the drifts.

NEVADA

MINERS STRIKE AT VIRGINIA CITY.

DIVIDE.—The Tonopah Divide shaft has been completed to 1000 ft. and cutting of a station at this depth has been nearly finished. On completion of the station a cross-cut will be driven to the vein, estimated to be 130 to 140 ft. distant. Judging from the rake of the ore-shoots on the 585-ft. level men familiar with the mine think it will be after November 1 when the shoot is entered at 1000 ft. The cross-cut to the vein at 800 ft. has been driven 25 ft. from the station. The plan of the management is to have the cross-cuts at 800 and 1000 ft. reach the vein simultaneously and, while it is regarded as probable that drifts will have to be driven south-east to open ore, they may have to be driven only a short distance, or ore may be found in the cross-cuts, as the shoots north-west of the shaft on the upper levels may at 800 and 1000 ft. be where the cross-cuts will enter them. The Victory winze is nearing 500 ft., where lateral work will be done. This winze is almost vertical and, depending on the grade and quantity of ore found, it may be extended to the surface and used as the main shaft.

VIRGINIA CITY.—The miners are on strike for an increase of \$1 per day to the present wage of \$5. Only enough men to keep the mines clear of water are working instead of the 350 to 400 formerly employed. The men at first voted to remain out until the increase had been granted, but later when representatives of the operators and miners met with Governor Boyle a committee of two, Edward Higgins, consulting engineer for the Gold Canyon Dredging Co., representing the operators, and Frank W. Ingram, the miners, was appointed to investigate wages and costs in Virginia City as compared with other districts in the State. The operators, in a statement, said the action of the miners was taken despite several contracts, some effective to January 1, 1921, and all of which call for 30 days notice to the operators before being nullified. The statement said: "In view of the absolute proof that the cost of living has already decreased, and will continue to decrease, we do not feel that a raise in wages is at all warranted at this time. We are ready and willing to resume operations under the old scale of wages. None of the organizations represented by the operators is opposed to unionism on the Comstock." The operators do not regard their statement as a refusal to grant an increase and it is thought this may be the result of the negotiations if the committee favors it.

DAYTON.—The 900-ton all-steel dredge of the Gold Canyon Dredging Co. was started on Sunday, September 4, by Mrs. Emmet D. Boyle, wife of Governor Boyle, with the Governor and other State officials present. Among the speakers were the Governor, Walter E. Clark, president of the university of Nevada; Dr. Aurelia Rhinehart, president of Mills college, Oakland, California; Edward Higgins, consulting engineer for the company; and R. H. Elliott, assistant general manager. The starting of the dredge was witnessed by 1500 people from Reno, Carson, and Virginia City and it was a big day in the history of the little town of Dayton. The consulting engineer said

the construction had been completed in four months actual working time. He explained that, because of the uneven surface of the bedrock, large boulders in the gravel, and high costs, the conditions under which the company would operate were not ideal. The dredge cost \$350,000 and it is estimated that the daily cost of operation will be \$400. Twenty men will be employed in three shifts at first, but this force will be reduced quickly to three to five men on a shift.

CARSON.—A high State official, when asked how Governor Boyle's name came to be associated with the Broken Hills, said the Governor inspected the workings and gave an opinion without knowing that George Graham Rice would promote a company to take over and develop the claims. The official said the Governor was angry when he saw his name linked with that of Rice, but that he was in a position in which he could do nothing. The official said he was surprised at seeing the name of Edward Malley,

side of the vein and a cross-cut is to be driven to the foot-wall. Assays of \$5 to \$6 are being secured. The Five to One tunnel has entered the vein that had been the objective of the work started last October. The vein was entered on the foot-wall side and the tunnel has been driven into it for 3 ft. Ore was not found and drifts will be driven after the hanging wall has been reached. The vein is composed of talc and quartz.

TULE CANYON.—The Silver Hills has announced that leases will be let on the Jagers claims, adjoining the Ingalls group on the west. There are several shafts in this territory that are from 50 to 100 ft. deep and there is low-grade ore in them. The company will mill the ore from the leases.

PIOCHE.—From January 1 to September of the present year, the Prince Consolidated Mining & Smelting Corporation has produced 36,152 tons of ore. At the present time shipments are running about 5000 tons per month.

CAMP AT THE MANDALAY MINE, JUNGO, NEVADA

State Treasurer, appearing at the top of Broken Hills stationery and declared he did not know how Malley came to be connected with Rice or why he should permit his name to be used. He also predicted that "there will, of course, be a smash-up one of these days". Conservative mining men regard with regret the entire Broken Hills affair, as they consider the name of Rice again connected with Nevada can result only in injury to the State. The name of Boyle and Malley connected with the promotion of the company with no explanation from either remains a mystery to their friends. Men who say they are familiar with recent work in the mine do not regard the result as being worthy of the columns of publicity being given Broken Hills in Nevada newspapers as 'boost' material, accompanying large advertisements in which the reader is sometimes reminded that Goldfield Mohawk stock went to \$20 per share.

GOLDFIELD.—The winze being sunk from the 910-ft. level of the Spearhead is 200 ft. deep and it will be continued to at least 500, according to R. S. Wilbur, superintendent. The winze, being sunk on an incline of 76°, is in a series of step-faults and it is penetrating quartz and alaskite alternately. It is now on the hanging-wall

The ore is of the usual grade, 75% of the total tonnage being derived from the Davison bed and the remainder from the Prince bed. Arrangements will shortly be completed for the resumption of the sinking of the main shaft to the lower bed.

Shipments from this district for the week ending September 7 totaled 3240 tons, of which amount the Prince Consolidated shipped 1900 tons; Virginia Louise, 800; Black Metals, 100; Bristol Mines, 250; Combined Metals, 150; Consolidated Nevada-Utah, 40.

ELY.—The directors of the Nevada Consolidated Copper Co. held their regular quarterly meeting in New York on September 10 and declared a dividend of 25c. per share, payable September 30. This will call for a total distribution of \$499,864.25, and bring the grand total up to \$46,768,616.60.

JUNGO.—The Mandalay Mines Co. has completed the erection of an 8 by 10-in. air-compressor, 15-hp. gas-engine, 6-hp. gas-engine, hoist, air-blower for the mine, sinking-pump, and other equipment to complete the plant. The shaft, 4 by 6 ft. in the clear, is to be sunk under contract to 120 ft. from the present depth of 80. A depth of 500 to 600 ft. can be reached with the equipment and

it is planned to reach this depth eventually, with drifts at 100-ft. intervals. The machinery has been bought and the shaft sunk to 80 ft. at a cost of less than \$14,000. The shaft is in ore containing silver glance that assays from \$20 to \$75 per ton, with a high silica content which keeps the treatment charge under \$1.50 per ton, according to the management. The shaft is nearly vertical. Part of a 35-ton shipment of \$35 sorted ore has been hauled to the station at Antelope and shipments are to be resumed when the 100-ft. level is reached. Work was started July 20, 1919, but little was done except build a camp and improve the roads to Jungo, Sulphur, and Antelope before cold weather. The spring and summer has been devoted largely to putting the machinery in place. The State engineer has given the company permission to use $\frac{1}{2}$ second feet of water. This gives possession of Mandalay creek and Dwyer springs, the latter on a mill-site which the company plans to utilize for the erection of a mill when mine conditions make a plant advisable. Water is pumped also from a 30-ft. well for household use. The amount of cash spent by the company has been lessened by the employees taking stock in part payment of their wages.

EUREKA.—The Mammoth Mining Co. is now shipping two carloads per day from its mill-dump to one of the Salt Lake valley smelters. The dump contains about 250,000 tons of material, which will average \$7 per ton in metal content. By use of a small engine and mine cars, the material is transported from the dump to the loading-station a short distance away; horses and scrapers being used to fill the smaller cars. The average cost of loading the material is about 35 cents per ton. Earl McIntyre, manager of the Mammoth property, states that from two to three carloads of ore per day is being mined. The company is doing considerable development work, the most important of which is the drift to the north-east on the 1500-ft. level. Another piece of development is being performed on the 300-ft. level.

NEW MEXICO

HURLEY.—The directors of the Chino Copper Co. declared a quarterly dividend of $37\frac{1}{2}$ c. per share on September 10, payable September 30. This will call for a payment of \$326,242.50, and will bring the grand total of such disbursements up to \$29,991,709.50.

UTAH

ORE SHIPMENTS TO THE SMELTER.—ACTIVITY AT OPHIR HILL CONSOLIDATED.

SALT LAKE CITY.—At a meeting of the directors of the Utah Copper Co. in New York on September 10, the regular quarterly dividend of \$1.50 per share was declared, payable September 30. This will call for the payment of \$2,436,735, and will bring the grand total of such disbursements up to \$109,072,927.50.

During the week ending September 4, the sampling mill of the Utah Ore Sampling Co. at Murray handled 82 carloads of ore from Utah mines; 9 from Nevada; 4 from

Montana; 2 from California; 1 from Idaho; and 1 from Canada. The Tintic mill of the same company handled a total of 88 cars of ore from Utah mines.

MARYSVALE.—The Tushar Range Metals Mining Co., a Pittsburgh organization, after two years of persistent development at its property here, recently made one of the most important ore discoveries in south-central Utah. Guided by geological conditions, the company drove a tunnel into the south wall of Pine canyon a distance of nearly 500 ft., and entered a lead-bearing bed of calcite, which was followed more than 200 ft. through primary lead, silver, and gold ore. At 795 ft. the company is sinking an incline winze, with the object of reaching the underlying quartzite. Officials state that each foot of depth is marked with improvement in the lead content and the size of the lenses of high-grade ore. The orebody, which has now been proved to be more than 30 ft. thick, will doubtless exceed 50 ft. before the quartzite-calcite contact is encountered.

PARK CITY.—An assessment of one-quarter of a cent has been levied on the capital stock of the Daly-Judge Extension Mining Co., payable September 25. The money derived from the assessment will be used to develop the property.

During the week ending September 4, eight mines in this district shipped a total of 2186 tons, as compared with shipments aggregating 2157 tons for the preceding week. The Ontario shipped 600 tons; Silver King Coalition, 582; Judge M. & S., 495; Daly-West, 239; Nail-driver, 110; Keystone, 55; Daly, 53; Park-Utah, 52.

BIG COTTONWOOD CANYON.—Development work at the Woodlawn mine is being steadily done under favorable conditions, according to W. J. Lawrence, the manager. Upon the lowest level, at a vertical depth of 600 ft., drifting has been carried forward a distance of 200 ft. westerly from the point at which the cross-cut from the winze from the main tunnel-level cut the fissure. Ore was found for the entire distance in this drift. A raise from the 600-ft. level to the main tunnel-level, 100 ft. above, is following good ore. This raise will also improve the ventilation. On the main tunnel-level, in the west drift, along the fissure, a raise is being made. It has reached a height of 80 ft. and there is 3 ft. of good ore showing. Ore is now being hauled from the mine to the loading bins in the canyon.

OPHIR.—The policy of the mining companies in this district is never to release much news concerning their activities. Nevertheless, development work of great interest and value is steadily being done. Most of the mines are more or less privately owned, and there is a lack of technical literature describing geological features. The largest property in camp is that of the Ophir Hill Consolidated, owned by former Senator W. A. Clark of Montana. This mine has a gross yield of between 35 and 40 million dollars to its credit, and at present, according to a conservative estimate, it is producing metal to the value of \$800,000 per annum. It is said that the management is planning to remodel its concentrator along up-to-date lines to improve its efficiency. The property at present is

shipping an average of two carloads of concentrate per day and one car of ore.

It is reported that the Ophir Silver Mines Co. has made a strike of excellent ore on the surface in the Buckhorn fissure. A force of men has been put to work at this place and a camp established.

At the mine of the Ophir Metals Co., a force of 30 men is employed in driving the tunnel, which is 1200 ft. from the portal. It should reach the old Lion Hill workings, from which some 3 million dollars' worth of ore was shipped. At a distance of 800 ft. from the portal, the Buckhorn limestone should be entered. In this it is expected that the same orebodies will be found in the fissure as were encountered in the Treasure Hill bed, some 500 ft. above.

TINTIC.—Shipments from this district for the week ending September 4 totaled 145 cars, an increase of 4 cars over the previous week. The Chief Consolidated shipped 40 cars; Tintic Standard, 30; Eagle & Blue Bell, 10;

later with a permanent installation. A contract has been awarded for the construction of an 11,000-volt power-line from the Tintic Standard to the site of the South Standard company's new shaft, a distance of two miles. The sinking of the shaft at the South Standard has reached the point where a hoist is needed, and the company is planning the installation of a modern hoist and compressor, both to be electrically driven. During the past few months, the company has erected the necessary surface buildings, and when the hoist and compressor are installed, development work will be undertaken in earnest. The South Standard is controlled by the same interests as the Tintic Standard.

BRITISH COLUMBIA

EXPLORATION AND DEVELOPMENT IS GENERAL.—DOLLY VARDEN AGAIN SHIPPING.

ALICE ARM.—The Dolly Varden railway is operating at capacity again. Notwithstanding the washouts, 4500

TAILING DUMP AT CORTEZ MINE, EUREKA COUNTY, NEVADA

Dragon, 10; Mammoth, 10; Iron Blossom, 8; Grand Central, 8; Iron King, 5; Bullion Beck, 4; Swansea, 4; Gemini, 3; Victoria, 3; Gold Chain, 2; Colorado, 2; Centennial-Eureka, 1; Griggs Huish Leasing Co., 1 car of concentrate.

Recent developments at the Plutus property, controlled by the Fitch interests, have been most encouraging, according to Cecil Fitch, manager. Recently a drift on the 1700-ft. level cut a few small stringers of quartz and tale, and assays showed 3 to 4 oz. of silver and 0.15 oz. gold per ton, which the officials believe indicates the close proximity of an orebody. Mr. Fitch states the drift will be extended until it cuts the fault-zone, and that later the company will do some additional prospecting at points where the best showings exist.

About 125 men are now employed in the construction of the Tintic Standard company's concentrating plant at Warm Creek. Two electric hoists are used for lifting materials to the proper elevation on the hillside. The boarding and lodging houses, warehouse, office building, machine and carpenter shops, and dwellings for employees have been completed. A 44,000-volt sub-station, two miles of 2300-volt line, and five banks of service transformers have also been installed. Some of the last construction is of a temporary nature and will be replaced

tons of ore was shipped from the mine to the Granby smelter, at Anyox, besides a small quantity of high-grade, which was shipped to the Tacoma smelter, as the Granby company does not care to handle this class of ore. In July 5600 tons of ore was shipped over the line. About 115 men are employed in the mine and a like number on the railway and in construction work. Work on the 500-hp. hydro-electric plant, at Clearwater lake, is progressing well. W. R. Ross has bonded the Moose mine to D. W. Cameron and associates for \$165,000. The same parties have made an examination of the Esperanza group, with a view to purchase. Some high-grade silver ore has been taken from surface operations on this property recently and a small shipment is being sent to the Tacoma smelter. Wolverton, Hammond & Bruggy have started work on the extension of the Silver Tip vein.

YMR.—John W. Shaw, who is superintending development work at the Texas Yankee Girl mine for the Mining Corporation of Canada, reports that the mine is developing well. Two 300-ft. raises have been made from the No. 5 level, and will be continued another 400 ft. to connect with No. 2 level. This work together with that on the intervening levels will block out a large body of ore. The raises have been driven on the vein, and are in good ore.

NELSON.—The Perrier mine, situated on Cottonwood creek on the slope of Morning mountain close to the line of the Great Northern railway, was recently taken over by a re-organized company with a capital of \$250,000 and the officers of which are C. E. Crossley, president; R. W. Hinton, vice-president; W. M. Cunliffe, secretary-treasurer. It was discovered in 1910 and named from the late King Edward's famous horse. Mr. Turner is one of the original discoverers. The main shaft of the mine has been sunk 120 ft. The present plant consists of a Huntington three-foot mill of five-ton capacity for treating ore from the drift. From this mill \$3300 in gold has been taken, other metals not having been recovered. There also are a Rand drill, a Rand hammer-stoper, and a three-drill Rand compressor driven by a Pelton wheel. There is an abundance of water and Messrs. Crossley and Turner claim they have invented an automatic pump to keep the mine free from water which will work for 12 months without attention. It is planned to put in a stamp-mill and a modern hoist. About 80% of the ore is free-milling.

A second vein has been discovered by surface stripping on the property of the Mountain Chief copper mine, Renata, on the lower Arrow lake. A tunnel has been driven exposing considerable mineralization, the ore, for the most part, being oxidized.

A new vein is reported on the Barnet Silver-Lead group at the head of Lemon creek. The new lode is similar and runs parallel to that on which work has been done. Already ore from this source is being sacked for shipment. The Barnett mine was re-opened by R. G. McLeod some four or five weeks ago. It has been a shipper in past years.

TRAIL.—A total of 11,257 tons of ore and concentrate was received at the smelter during the last ten days of August; the Consolidated company's mines supplying 9854 tons. The other shippers were: Bluebell, Riondell, 156 tons; Canada Copper Corporation, Greenwood, 11; Iron Mask, Kamloops, 83; Josie, Rossland, 296; Mandy, Le Pas, 372; Mayo, Yukon, 3; Monarch, Field, 37; North Star, Kimberley, 251; Providence, Greenwood, 72; Sally, Beavertell, 45; Silver Standard, New Hazelton, 41; Skylark, Greenwood, 16; and Venus, Carcross, Yukon, 20. Up to date this year, the Mandy mine, at Le Pas, has shipped more than 7000 tons to Trail.

STEWART.—It is reported that the present bond holders of the Big Missouri group of mineral claims, Salmon River, Portland Canal district, do not intend to continue development work. Operations have been under way for some time by a syndicate known as the Pacific Coast Exploration Co. prominently identified with which is Sir Donald Mann, of Toronto. Both diamond-drills, with which exploration work has been in progress, have been withdrawn. The only information made public, and it is unofficial, is that the Big Missouri presents an unusual problem, that the small amount of drilling done has not given satisfactory results, and that the complete exploration of the entire mineralized zone is a work of such magnitude that the company does not feel disposed to continue at present.

ONTARIO

RECENT DEVELOPMENTS AT KIRKLAND LAKE.

TORONTO.—At a special meeting of the shareholders of the Dome Mines Co. on September 7 the proposal of the directors to purchase the property of the Dome Extension Co. was unanimously ratified. The Dome Extension shareholders will receive 76,667 shares of Dome stock, being one share of Dome for every 30 shares of Dome Extension.

The arrangements made by the Davidson Consolidated in England, by which \$1,125,000 will be secured for development and the construction of the mill, is opposed by some of the shareholders, who object to optioning 50% of their stock to the English interests, which will prevent them from taking advantage of a favorable market to dispose of it. G. C. Crean, president, has issued an explanatory statement recapitulating the terms of the agreement under which, in addition to the 1,500,000 shares of treasury stock to be sold outright, the English syndicate requires a two-year option on 2,000,000 shares now held by shareholders the exercise of which would give them a controlling interest. To meet this demand each shareholder must option 50% of his stock, otherwise the deal will fall through and the company will have no other alternative than to assess the shareholders to provide the funds required to build the mill and carry on development.

A diamond-drill machine is being taken to the Clifton, where exploration will be undertaken to determine the extent of the continuation of orebodies already found.

KIRKLAND LAKE.—The development of the new eastern portion of the Kirkland Lake field is attracting much attention, the results of operations so far having been of a decidedly encouraging character. Promising features of this section are the great width of some of the veins opened up, and the existence of veins containing visible gold as well as gold tellurides in close proximity to contacts between conglomerate and porphyry. This is a condition almost identical with that shown on the surface in the proved part of the Kirkland Lake area. The Bidgood, Wood-Kirkland, Crystal Lake, Pinelle Kirkland, King Kirkland, Lebel Ore, and others on which development has recently been begun, are all located on the main belt of favorable rock formation extending eastward from the producing area.

BOSTON CREEK.—It is stated that visible gold and gold tellurides have been encountered at the Miller Independence at a depth of 500 ft., the orebody being apparently the downward continuation of the rich ore-shoot developed in the upper levels of an inclined shaft. This work was only carried to a depth of 200 ft. The Patricia has been optioned at a high figure to T. J. Flynn.

COBALT.—New equipment is being installed at the Kerr Lake to handle a large tonnage of low-grade ore on the dumps. It includes a mechanical shovel, automatic loader, and crushing machinery. The ore will be shipped by aerial tram to the Dominion Reduction Co. for treatment. Production is being maintained at about 50,000 oz. of silver every three months.

THE MINING SUMMARY

CALIFORNIA

Amador County.—The Central Eureka at Sutter Creek has been sinking in pay-ore from the 3100-ft. level for several weeks. It is a new find, and although the area is unknown the prospects are so good that the company is planning an underground hoist for next year. The surface plant has about reached its limit. The result of the conferences in San Francisco between representatives of the Argonaut and Kennedy companies has not been made public and the situation is unchanged. New pumping machinery has been added to the South Eureka mining plant, which is connected with, and drains the water from, the Central Eureka. After months of work, the restraining dam constructed by the Crocker Estate company of San Francisco for the purpose of impounding tailing from the Elephant hydraulic mine, is completed. It is 30 ft. high and 425 ft. long. Washing is expected to commence on November 1.

Bakersfield.—The California Rand silver mine, in the eastern part of Kern county, has \$2,000,000 in ore in sight, and is paying \$25,000 monthly dividends to its stockholders, mostly in Bakersfield, Taft, and Fellows, according to reports received here. The California Rand property, which is the biggest producer in this section since the days of the Yellow Aster, has been producing for two years, and the ore is said to run as high as \$50 per ton. J. W. Kelly and Hamp Williams discovered the California Rand mine, and Kelly recently sold his interest to E. L. Blanck of Fellows for \$200,000. Blanck also bought the John Nosser interest for \$80,000. Two years ago one-eighth interest in the mine sold for \$500.

Calaveras County.—Exploration work is general and all available men are busy. Outterbidge and Howe are re-opening the Smith mine, formerly known as the Ketz. They employ 17 men and are driving a 900-ft. tunnel with the object of working the vein 1100 ft. below the outcrop. George Prentiss is developing a prospect on the North Fork of the Mokelumne. He has driven 60 ft. on a 4-ft. vein of \$50 ore. The West Point Gold company is commencing work with 20 men on some low-grade properties on Licking Fork. The North Star has taken over the Defender and Lone Star groups and will spend \$500,000 in sinking.

Imperial County.—Baverstock & Staples report that litigation over the Paymaster and President mines is nearly at an end. The Anaheim M. & M. Co. is preparing to treat the old tailing and re-open the old workings.

Nevada County.—Repairing the New York Hill and other shafts of the North Star is proceeding. The new electric engine to take the place of mules underground has arrived. At the Idaho-Maryland the water in the incline Canyon shaft at the bottom of the 1100-ft. shaft, is being kept at a standstill. The Alcalde continues to produce rich specimen ore from the shoot uncovered last week. The extent of the find has not been determined. Hand-mortars are used in reducing much of the ore extracted.

Placerville.—Charles E. Swezey of Sacramento reports that the Grit Gold Mining Co. is planning to work the claims formerly held by Walter P. King and have found some extraordinary high-grade ore. The Hines-Gilbert mine is taking out ore preparatory to commencing operations in its 10-stamp mill.

Plumas County.—The Engels, Walker, Gruss, Beardsley, and other properties are producing, with the Engels and Walker shipping heavily. Diamond-drills at the Engels have demonstrated the occurrence of large deposits of profitable ore below the No. 7 level to a depth of 400 ft. The 200-ft. shaft connecting levels 6 and 7 has been completed and blocking of ore in this area begun. The flotation mill is making an excellent product from the Engels and Superior mines and activities are being increased as rapidly as more miners can be secured.

The Walker Copper Co., a subsidiary of the Anaconda Copper Co., has completed the aerial tramway to Spring Garden and is shipping its concentrate to the railroad station by way of the new transportation system. The tramway eliminates costly motor-truck service formerly in use. Diamond-drills have extended the ore limits of the main Walker deposits and proved that the orebodies extend to great depths beyond the main levels.

Sierra County.—The new rotary mill on the Kirkpatrick mine near Downsville is reported to be operating efficiently on the high-grade gravel.

IDAHO

C. J. Diebel, of Spokane, president of the United States Silver Lead Mines Co. has returned from a visit to the property in the Coeur d'Alene. Another 35 ft. in the cross-cut is expected to reach the vein at a depth of 135 ft. A. M. Nash is manager. Paul Liver of Wallace was re-elected president and manager of the Giant Mining & Development Co. at the annual meeting. A cross-cut is being run which is expected to cut the vein soon. The property is on Sunset Peak in the Coeur d'Alene. The Idaho-Northern Mining Co. of the Coeur d'Alene is about to extend its lower tunnel 1600 ft. additional depth on the orebody. Work was suspended by this company for a time four years ago. O. M. Nordquist is arranging for the resumption and Oscar Eckman will be superintendent. Robert N. Bell, mine inspector of Idaho for many years, will take over and operate the Clayton mine in Custer county. Three carloads of ore were shipped from the Jack Waite in the Coeur d'Alene the last of the month. The ore goes to Utah. The shipments of zinc and of lead-silver ore and concentrate of the Consolidated Interstate-Callahan Mining Co. were 4576 dry tons less in the quarter ended June 30, than last previous quarter.

Coeur d'Alene.—The Hecla Mining Co. will disburse its regular quarterly dividend of \$150,000 on September 28. This disbursement will increase the total of dividend payments this year to \$500,000, an extra of \$50,000 or five cents per share, having been paid with the regular dividend of \$150,000 in June. This will bring the grand total up to \$8,355,000. James F. McCarthy, president and general manager, said recently that the company was hoisting from 600 to 700 tons daily. He said that the main orebody, opened on the 2000-ft. level, had been followed by drifting for 500 ft. Its average width is 16 ft., and of a grade similar to that on the 1600-ft. level. The company is now employing 300 men and operated six days per week.

Gilmore.—The Pittsburgh-Idaho mine in the Gilmore district of Lemhi county is now shipping 30 cars of ore per month. The ore is a carbonate, averaging 25% lead and 12 to 15 oz. silver per ton. The 'Latest Out' property, in the same district, is shipping about 20 carloads per month.

Kellogg.—The raise in the Nabob Consolidated mine attained a point 175 ft. from the Nabob tunnel level, according to Henry Thomson, mill superintendent. This is 62 ft. from the Sidney tunnel level, the objective in the drive. The work is proceeding rapidly. Ground is being broken at the rate of five feet per day.—A vein has been found in the face of a 250-ft. tunnel on the property of the Central Idaho Gold Mining Co., near the Big Buffalo mine, in Buffalo Hump, according to reports. This is a blind vein, the main vein being 240 ft. ahead.—All the ore-bins of the Highland-Surprise property on Pine creek in the Coeur d'Alene are filled from ore mined during development. The ore is high-grade. Only a small force is working at present, but the company is considering plans for increasing the force, connecting the two levels by a 200-ft. raise, and possibly it will decide to start the mill.—The big smelter of the Bunker Hill & Sullivan company is doing a greater business than ever and steadily increases its force. Many mines are commencing or resuming work, and the fact that unpatented claims must be worked this year is making quite an important addition to the number of men employed in the district. The railroad to be built up Pine creek will greatly benefit this section.—Reports from the Lookout Mountain mine of the Pine Creek district of the Coeur d'Alene confirms the belief that the strike recently made is important. Two feet of good copper-silver ore was found and it is said that some of it looks as though it would pay to ship without milling.—At a meeting of the stockholders of the Bristol Mining Co. at Kellogg recently, a consolidation proposal with the Jim Blaine Silver Syndicate was accepted and the two properties merged. Machinery will be erected and the tunnel driven from the lowest point possible for the development of both veins. This will require about 1500 ft. of work and will secure over 800 ft. of depth on the vein. The properties are situated on the east fork of Pine creek, about half a mile from the fork, and the same distance from the proposed Pine Creek railroad.

Ophir.—Guy R. La Coste, president and general manager of the Ophir Silver Mines Co., accompanied by F. M. Wichman, consulting engineer, have been here. Mr. Wichman is making a thorough examination of the property, preparatory to a report. On the basis of this report decision will be made as to whether or not it will be advisable to open up the lower tunnel, which is in the formation a distance of 700 ft., and follow a strong vein of silver ore which is making toward and under the contact, but 70 ft. from the face of the adit. At present considerable water is making in the tunnel.

OREGON

Gold Hill.—Rich ore has been discovered in the Sylvanite group of gold mines by Victor W. Brown and associates of Pittsburgh, lessees. This property is the only quartz mine among those in operation in this region. Gold mining has been almost wholly suspended in this region since 1914, excepting the hydraulic placer mines which have extensive water-rights. The new find was made in the old workings at a depth of more than 600 ft., and contains ore worth from \$20 to \$50 per ton in gold and silver. The several mines constituting the group, known as the Simmons, Cheney, Haff, and Ray mines, have been gold producers for 30 years.

Tungsten was discovered in this property in 1916 by Ray & Haff of Gold Hill, who were operating the mine. The tungsten occurs in small stringers with quartz, and ore containing from 2 to 40% tungsten was extracted. The veins carrying the best grade of tungsten have been developed only to a small extent and the tungsten resources of the mine, therefore, have not yet been determined. The increased amount of this metal required for tool steel and incandescent lamps has kept up the interest of prospectors in the district.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Karl Eilers is in San Francisco.

Henry Krumb, of Salt Lake City, is in New York.

J. H. Hottendorf, of Bridgeport, Oregon, is at Yreka, California.

A. E. Roesler is now operating at West Point, in Calaveras county.

S. L. Boyes has moved from Grants Pass, Oregon, to Los Angeles.

Walter H. Wiley has returned from the Coeur d'Alene to Los Angeles.

L. Venn Brown has returned from King island to Sydney, New South Wales.

Samuel W. Cohen, of Montreal, is in Newfoundland examining mining property.

O. M. Kuchs, general manager for the International Smelting Co., of Salt Lake City, is at Chicago.

Frank A. Love, recently of Inspiration, Arizona, is now with the Alvarado M. & M. Co., at Parral, Mexico.

C. W. Purington has left Hakodate, northern Japan, for an examination of the coalfields of northern Sakhalin.

George C. Bartells, who has been conducting research work at the Murray smelter, Utah, has returned to St. Louis.

Charles C. Selbie, of Pasadena, California, sailed from New York on September 4 for the Congo, by way of Antwerp.

G. Howard Birch and **Arthur J. Striker** have removed their offices from 160 Broadway to 522 Fifth Avenue, New York.

Ernest Levy, on his return from Cuba, has gone to London to accept a partnership in the firm of Alexander Hill & Stewart.

R. O. Dobbs has been making an investigation of the Ada H property, adjoining the Spruce Monarch mine near Wells, Nevada.

R. S. Baverstock has returned to Los Angeles from a trip to the Paymaster and President mines in Imperial county, California.

Frank P. Knight, of Boston, president of the Iron Cap Copper Co., recently visited the company's properties at Copper Hill, Arizona.

Sidney R. Stanford has left the Constancia mine, to become mine superintendent for the Nicaragua Mining Co., at Bluefields, Central America.

Charles E. Prior has left the Premier mine in British Columbia, to accept a position on the staff of the Mexican Corporation, at the Fresnillo mine, in Mexico.

T. Hasegawa, **K. Mimura**, and **J. Matsumoto**, connected with the Sumitomo copper works at Osaka, Japan, have been visiting mining and metallurgical plants in Utah.

T. R. Arnold, formerly chief electrician for the Arizona Copper Co., has accepted the position of electrical engineer for the Southwestern Portland Cement Co. of El Paso.

Howland Bancroft has accepted the appointment of manager for the Sinclair Panama Oil Corporation and will move to Panama forthwith. He sails from New York on September 22.

L. D. Ricketts, who has been spending the last few months in Santa Barbara, California, is making an inspection of the Inspiration and Calumet & Arizona properties, prior to visiting New York.

Carl A. Allen, State Mine Inspector of Utah; **George Murphy**, superintendent for the Spring Canyon Coal Co.; and **R. M. McGraw**, general superintendent for the United States Fuel Co. were among those who attended the convention at Denver, beginning September 9.

Eastern Metal Market

New York, September 8.

The prevailing dullness in all the markets has been rendered more pronounced by the Labor Day holidays.

Buying of copper is at a low ebb but inquiries are more numerous.

The tin market has a better tone with some buying by consumers.

The lead market has declined because of offerings of imported metal.

The condition of the zinc market is similar to that of the lead.

There is no material change in antimony.

IRON AND STEEL

The waiting attitude of buyers of pig-iron and steel has been more marked in the past week, says 'The Iron Age'. Pressure for early supplies of everything in finished steel, with the possible exception of tin plate and wire products, has disappeared. Buyers generally seem confident that they can get steel for 1921 when they need it and at prices not above those of today.

Pig-iron production in August, under better railroad-operation, rose to a point only exceeded this year by March and in 1919 by January alone. The total was 3,147,402 gross tons, or 101,529 tons per day, as against 3,067,043 tons in July, or 93,965 tons per day. September promises further increase. Twenty-three furnaces were blown in last month and five were blown out—a net gain of 18.

With the large volume of unshipped orders that is on the books of the mills, prices are little affected by the halt in buying, but the basis of future contracting is concededly a two-sided question, whereas in July the shortage in steel supply seemed the decisive factor.

COPPER

Despite the fact that buying of copper has shown no improvement in actual sales, inquiry from large consumers is increasing which is taken as an evidence that stocks are being depleted and that a buying-movement will, and must, materialize inside of two weeks or so. While most of the large producers are adhering to the 19c., New York, quotation for both Lake and electrolytic copper, there are evidences that a few are taking some business as low as 18.75c. and that the light demand afloat is being taken care of at around those levels by these few sellers as well as by the smaller producers and dealers. Foreign sales continue moderate and satisfactory under the circumstances. On the whole sentiment in the trade is better than for some time and there is a feeling that better times as well as better prices are near at hand. The British market has been almost buoyant the entire week.

TIN

For the first time recently there have been sales made to consumers. Two importers report moderate buying last week from this source, some for October-November arrival and some for September-October shipment from the East at 45.50 to 46c. On the whole the market has been only moderately active. There has also been an increase in business done on the New York Metal Exchange, total sales for the week amounting to about 250 tons at prices ranging from 45 to 45.50c., depending on the position, mostly future shipment. Last Thursday one buyer had to sacrifice 100 tons, ex-ship at dock, by selling it under the rule at 45.12½c. to 45.50c. in four lots. On Friday the market closed higher with spot at 45.50c. and futures held at 46c., at which level some business was done. Spot Straits New York, yesterday was 45c. The London market yesterday was £264 10s. per ton for spot standard, £270 10s. for future standard, £272

for spot Straits, and £280 for Singapore, all lower than a week ago. Deliveries of tin in August are reported at 3745 tons, of which 3400 tons came in at Atlantic ports. The quantity in stocks and landing on August 31 was 3256 tons. Total tin imports to September 1, 1920, were 36,688 tons, as compared with 11,556 tons to September 1, 1919.

LEAD

There is little new to be said. The controlling factor is the importation of lead which is a cause of some pressure. While demand in general is not heavy, several sales have been made at around 8.50c., New York. Consumers are understood to have, in some cases, expressed hesitation in accepting foreign lead on the assumption that it may not be as good in quality as American metal. The fact that it has been and is being offered in competition with domestic lead is the basis of an argument that the domestic price should also fall. Thus far the quotation of the leading interest has not been changed and is still 8.75c., St. Louis, or 9c., New York. We quote the outside market at 8.50c., New York, or 8.62½ to 8.75c., St. Louis, the latter being higher than New York, an unusual condition.

ZINC

The situation in this market is similar to that in the lead in that imports of zinc are a source of weakness but not to so pronounced a degree as in the other case. There continue to be offerings and sales of prime Western zinc for re-shipment from England which have depressed the Eastern market to a level practically equal to the Western or St. Louis quotations. Prime Western for early delivery is quoted at 7.90 to 8c., New York, and at 7.90c., nominal, St. Louis. Consumers are uninterested and are not making inquiries, much less buying, and producers insist there is no profit in selling at present levels. They therefore sell only under compulsion to regular consumers.

ANTIMONY

This market is inactive with quotations unchanged at 7c., New York, duty paid, for wholesale lots for early delivery. Jobbing lots are held at 7.25 to 7.50c.

ALUMINUM

The price of the leading interest is unchanged at 34.90c., f.o.b. producer's plant, for wholesale lots of virgin metal, 98 to 99% pure, for early delivery, while other sellers are offering foreign and other metal at 32 to 33c., New York.

ORES

Tungsten: The market is quiet and devoid of features. Quotations are unchanged at \$5 to \$5.25 per unit in regular concentrates, according to grades, quantity, and delivery.

Ferro-tungsten is unchanged at 80c. to \$1.05 per lb. of contained tungsten.

Molybdenum: Dullness pervades this market with prices unchanged at 75c. per lb. of MoS₂ in regular concentrates.

Manganese: The market is weak with buyers apparently unwilling to pay more than 55c. per unit, seaboard, for high-grade ore, while sellers are asking 65c. per unit.

Manganese-Iron Alloys: Demand for both ferro-manganese and spiegeleisen is light. Quotations are unchanged from the recent decline and are \$170, seaboard, as a base for delivery this year, for ferro-manganese, and \$82.50 to \$85, furnace, for the higher grade of spiegeleisen. There are indications that some electric producers will abandon production of ferro-manganese. One Eastern electric ferro-alloy maker is producing silico-manganese containing 15 to 20% silicon and 45 to 55% manganese which is selling for \$200 to \$225 per ton, furnace.

THE METAL MARKET

METAL PRICES

San Francisco, September 14

Aluminum-dust, cents per pound.....	85
Antimony, cents per pound.....	9.50

EASTERN METAL MARKET

(By wire from New York)

September 13.—Copper is dull and easy. Lead is quiet and soft. Zinc is inactive but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE FRENCH LOAN

American investors are given tomorrow the opportunity to subscribe at par to \$100,000,000 bonds of France. Already the application assure an over-subscription. There are abundant reasons why this should be so, says the "Boston News Bureau", under date of September 8. There are first, and also foremost, the cold-blooded reasons of dollars and cents. France, which once used to issue 3% rentes, is compelled by the world-wide post-war conditions of capital cost to offer 8% now—just as Switzerland also recently had to do. Our own government is again borrowing for a year at 6%. More than that, France binds itself to devote \$4,400,000 per year to a sinking-fund that shall buy back these 25-year bonds at 110, and after five years a portion of the bonds are to be drawn by lot for such redemption at 110.

There is a larger business reason than the individual one of investment attraction. These bonds represent really an extension of previously granted credit. In fact the Anglo-French 5s, maturing October 15, are applicable in subscription to their 8% successors—so far as France was concerned. That need of credit extension has been dimmed into the care of American investors as the obvious outstanding requisite of the international economic situation. It is the procedure which any intelligent merchant would apply under parallel conditions in his own business. We as a nation have been merchants on a huge scale. Here is one of the first concrete cases.

England and France jointly borrowed the \$500,000,000 about to mature. For patent reasons of greater relative wealth, less war hardship, and more control of exchange and credit facilities, England has been in position to take care fully of its half when due. She sent us about \$75,000,000 gold and arranged for the rest through security sales, buying of exchange, and other devices. England's exports today exceed her imports when to the former are added her "invisible exports"—investment interest, freight, and insurance earnings. She is still netting about \$50,000,000 per month on capital abroad, against nearly \$100,000,000 per month before the War.

But France is not so advantageously situated. Yet she is easily able to offer the other business incentives and security that justifies her seeking partial credit. She attends to \$150,000,000 of her obligation by funds already assigned and also by gold to be sent us, of which \$4,000,000 is already on the water. There will be a big influx of gold hither this fall to bolster our slowly dropping reserve ratios.

There is the further promise of security in the steady recovery of her industry at home and her trade abroad—plus, at bottom, the reason and character of the French business incentive. In the first seven months of this year France has improved her trade position almost 32%, or by a reduction in the adverse balance from 14,250,000,000 to 9,750,000,000 francs. While her imports—largely raw materials—increased 2,738,000,000 francs, her exports gained 7,230,000,000 francs.

Every American returning from France—the latest being Mortimer Schiff—bears witness testimony to the marked progress in economic reconstruction already achieved by the French. And after the Anglo-French maturity is taken care of the exchange value of the franc should materially improve.

A member of the French loan syndicate is quoted as saying: "Acceptance of this responsibility by us is a very clear duty that will be recognized by every thoughtful American". When the Anglo-French loan was made, the late James J. Hill led in pointing out our duty then.

MONEY AND EXCHANGE

Foreign quotations on September 14 are as follows:

Sterling, dollars:	Cable	3.46 1/4
	Demand	3.47
France, cents:	Cable	6.56
	Demand	6.57

Marks, cents:	Demand	1.77

Book Reviews

Silver. By Benjamin White. Pp. 140, ill. Sir Isaac Pitman & Sons, Ltd., London. For sale by 'Mining and Scientific Press'. Price, \$1.

An odd combination of historical, technical, industrial, statistical, and monetary information regarding silver, is this small volume. It starts with a dash of geology and ends with a large table showing the price of bar silver in London by months from January 1833 to December 1918. There is much of general information in the book for the casual reader, but no particular phase of the subject is treated at any length. It is written as one of a series devoted to "commodities". The author correctly defines silver as a commodity and shows its "intimate association with the daily life of man".

Shop Mathematics. By Erik Oberg and Franklin D. Jones. Pp. 275, ill., index. The Industrial Press, New York. For sale by 'Mining and Scientific Press'. Price, \$3.

This book is intended for machinists, tool-makers, and apprentices, primarily for those whose previous mathematical education has been incomplete. The book reviews arithmetic, and discusses such elementary algebra, geometry, and trigonometry as is especially applicable to shop calculations. Most of the book is devoted to the application of the mathematical theories already discussed to the solution of machine-shop problems, such as setting tapers, change-gears, indexing on the milling machine, and gear-cutting. The book would be improved by the addition of an appendix containing the mathematical tables most commonly used in machine-shop calculations, but, even as it is, it will be useful to shop-men.

Elements of Steam and Gas Power Engineering. By Andrey A. Potter and James P. Calderwood. Pp. 297, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

This book is designed primarily as an elementary textbook for engineering students but could also be used to advantage by others interested in the subjects discussed. The first chapter is devoted to the fundamentals of power engineering, following which the various divisions of steam power-plant work are discussed including engines, turbines, boilers, auxiliaries and accessories, a chapter being devoted to each of the principal divisions of the subject, including power-plant testing. Internal-combustion engines are next considered, including general engine-design, fuels, and auxiliaries, particularly carbureters and ignition systems. Chapters are also devoted to locomotives, and to automobiles, trucks, and tractors.

Retaining-Walls. By George Paaswell. Pp. 269, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

The construction of retaining-walls dates back to prehistoric times, but, as the author points out, scientific design is comparatively modern, while the increasing use of reinforced concrete calls for something more accurate than the empirical methods frequently used with the gravity-wall. The present volume is divided into two parts of approximately equal length. Part I, after discussing the various methods of computing earth pressures and surcharges, considers gravity-walls, reinforced concrete walls, and various special wall-sections. A chapter is also devoted to temperature, shrinkage, and other factors of general influence. Part II, on construction, discusses the plant required, form-work, and general methods of constructing both concrete walls and walls other than concrete. Architectural treat-

ment, drainage, waterproofing, surveys, and office work are also considered. An appendix contains skeleton specifications and a bibliography. The book will be of value to anyone designing or constructing a retaining-wall.

Electro-Deposition of Metals. By Dr. George Langbein and William T. Brann. Eighth edition. Pp. 375, ill., index. Henry Carey Baird & Co., New York. For sale by 'Mining and Scientific Press'. Price, \$7.50.

This is the eighth edition of a standard work; it has been revised and enlarged so as to serve as a thoroughly comprehensive textbook to those who desire to learn about the plating and finishing of metals. It is written in plain and understandable English and gives a number of valuable formulas for the solutions used in the trade. In the main it is a translation from the German by George Langbein, but it includes many additions and revisions by William T. Brann, the translator. From the chapter devoted to an explanation of the related phenomena of magnetism and electricity, the reader is led to an account of the sources of the current used in the electro-deposition of metals, and then to a description of an electro-plating establishment. Then come details as to the preparation of the metallic objects, the deposition of the various metals. We commend the volume to those at all interested in an increasingly important phase of metallurgy.

Geology of the Mid-Continent Oilfields. By T. O. Bosworth. Pp. 282, ill., index. The Macmillan Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

Although prior to 1903 their output was negligible, the Mid-Continent fields, including Kansas, Oklahoma, and northern Texas, have up to the present time produced nearly one-sixth of the total from all the fields in the world since the drilling of the Drake well. Development has been so rapid that the available information regarding the fields has hardly kept pace with it, and such information as is available is scattered, and is found mainly in various bulletins of Federal and State bureaus. The present volume covers the principal facts about the geology of the various fields and, in addition, gives references to the sources from which more detailed information can be obtained. Besides the discussions of the geological structure, there are chapters on the character of the oil in the different fields, on the natural gas found in some of the fields, on the salinity of oilfield-waters, and on the production of gasoline from natural gas. The man who wants to inform himself regarding the Mid-Continent field will need this book.

Popular Oil Geology. By Victor Ziegler. Pp. 166, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

That in two years a second edition of this little book has become necessary is in itself an indication of its usefulness. The preface states that the book is designed for the man without technical or scientific training. As such it gives a sort of birdseye view of the subject with particular reference to the Mid-Continent and Rocky Mountain fields. The first chapter is devoted to the general history and statistics of the petroleum industry. The next discusses the physical and chemical properties of oil and gas, following which there is a brief discussion of the various theories of the origin of oil and gas. Several chapters are then given to a discussion of those geological phenomena that affect the migration of oil, and to the application of a knowledge of these phenomena to prospecting for oil. A chapter is devoted to the oil-shale industry and the final chapter discusses oil investments. The principal differences between the second edition and the first are the rewriting of the chapters on oil-shales, the migration of oil and gas, and the anticlinal theory.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

IMPROVEMENTS IN BULK-CARGO HANDLING

In the past four years several factors have stimulated interest among shippers of heavy bulky materials in a cheaper and more rapid scheme of handling such commodities. The manufacturers of apparatus, especially the pioneers in this line, started a movement in this direction some twenty years ago, and succeeded in getting a limited number of plants installed as early as 1902. The development of plants for handling large tonnage of coal and iron ore was the most obvious necessity and it was naturally the first problem attacked on a large scale. The necessity for such develop-

covers an automatic ore-unloader carrying a 15-ton clam-shell bucket on the unloader leg and designed to make a complete cycle or round trip in 50 seconds. The machine electrically operated throughout is shown in Fig. 1.

The unloader consists of a main framework mounted on trucks which travel along the runway-rails that are placed approximately as shown in the illustration. The main framework extends back beyond the rear runway over a temporary storage pile where the ore can be discharged if desired. It is then picked up by the ore-bridge and carried to the stockpile. Between the front and rear runways, space is pro-

Electrically-Operated Ore-Unloader

ment centred around the Great Lakes region and the first plants were built in this vicinity. The short season of navigation from the Minnesota, Wisconsin, and Michigan mining districts to the blast-furnaces of the lower lakes and the Pittsburgh district, require a movement of twelve-month supply of ore in about seven months. The coal supply of the States bordering on the iron-ore region was largely taken from the lower lakes on the return trip of the same boats. In order to perform this task with the minimum operating costs, it was necessary to provide machinery for cheap and rapid discharge of cargo from ship to dock or railroad, and vice versa, the length of time the ship was tied up to the dock being a vital factor in costs. The result has been a high state of development and concentration of bulk cargo handling plants in the Lakes region. In the late nineties the Wellman-Seaver-Morgan Co. brought out its ore-unloader, each machine capable of handling ore at a rate from 500 tons per hour, upward.

A recent contract with the Lehigh Valley Railroad Co.

provided for railroad tracks where ore-carrying cars are placed under the machines and loaded with ore for transportation to the furnaces. The girders of the main framework form a support for runway-rails, on which a trolley travels. This trolley supports a balanced walking beam, from the outer end of which a stiff bucket-leg depends. At the lower end of this leg is the bucket, which is operated by machinery placed on the walking-beam. All horizontal movements of the bucket are accomplished by moving the trolley backward and forward on the girders. The vertical movements of the bucket are accomplished by the operation of the walking-beam. The forward portion of the beam being out of balance, the bucket descends by gravity as soon as the brakes of the hoisting mechanism are released.

Only two men are required for the entire operation of one of these machines. One of the operators, whose station is in the bucket-leg directly over the bucket-shells, controls all of the motions of raising and lowering the bucket, of traveling the trolley back and forth, and moving the ma-

chine along the dock from one hatch to another. The second operator is stationed in a cab on the larry and from this station he controls the movements of the larry, the operation of the larry-gates, and the weighing of the ore.

Some idea of the capacities of unloading by this method may be derived from a record which was made in Ashtabula by eight machines of this type having a capacity of 15 tons each, unloading seven boats having a total capacity of 70,000 tons in 22 hours actual time. At another point, four machines working in boats having capacities of 13,000 tons have unloaded these cargoes in about three hours and twenty-five minutes.

In addition to the vertical movement, which is given to the bucket-leg by means of the walking beam, it also has a motion of rotation around its vertical axis. This motion is

business or occupation and to enter, individually or collectively, into any lawful contract of employment either as employer or as employee.

II—The Open Shop

The right of employer and employee to enter into and to determine the conditions of employment relations with each other (without reference to the affiliation or non-affiliation of either with any organization) is an individual right of free contract possessed by each of the parties.

III—Right of Association

All men possess the equal right to associate voluntarily for the accomplishment of lawful purposes by lawful means. The association of men whether of employers, employees, or others, for collective action or dealing, confers no authority

Clam-Shell Bucket in Operation

introduced to enable the machine to reach along the keel of the boat and clean up ore between hatches. The distance from point to point of bucket-shells when open is approximately 21 ft. About 97% of the ore is removed from the boat without hand labor. Records of fifty machines in operation indicate that this type of machine will handle ore at 2½ to 4½ c. per ton including all fixed charges, and records of as high as 783 tons of ore per hour per machine from tie-up to cast-off of boat have been made. The Lehigh ore-unloader will be installed at the Claremont terminals, New York harbor, to handle ore from Chile and Cuba.

over, and must not deny any right of, those who do not desire to act or deal with them.

IV—Responsibility of Combinations

The public welfare, the protection of the individual, and sound employment relations equally require that all associations or combinations be subject to the authority of the State. As the public interest is paramount, full publicity of facts of industrial relations is necessary.

V—Obligation to Secure Production

To develop, with due regard for the health, safety, and well-being of the individual, the maximum capacity and output required of industry is the common social obligation of all engaged therein.

VI—Wages and Management

The wage of labor must be drawn from the product of industry and must therefore be earned and measured by its contribution to production. All employees are entitled to complete business information in matters affecting the terms of their employment; and frankness is essential. In order that the worker, in his own and the general interest, may develop his full productive capacity, it is the duty of management to assist him to secure regular employment suited to his abilities, to furnish him with incentive and opportunity for self improvement, and to provide proper safeguards for his health and safety.

VII—Hours of Labor

The number of hours in the work day or week in which re-

FUNDAMENTAL PRINCIPLES OF INDUSTRIAL EMPLOYMENT RELATIONS

Employment relations should accord with and express ideals of justice, equality, and individual liberty. The terms of employment should conform to the essential requirements of economic law and should, through intelligent co-operation, based on a recognition of mutuality of interest, conduce to high productive efficiency. They should reflect an effort to realize ideals of individual and social betterment.

*Principles

I—The Employment Relation

Every person possesses the right to engage in any lawful

*Proposed by Committee on Labor of Associated General Contractors of America.

quired maximum output, consistent with the well-being of the workers, can be maintained in a given industry should be ascertained by careful study and never should be exceeded except in case of emergency. One day of rest in seven, or its equivalent, should be provided.

VIII—Adjustment of Employment Relations

Adequate means satisfactory both to the employer and to his employees, and voluntarily agreed to by them, should be provided for mutual discussion and adjustment of employment relations.

IX—Community of Interest

The greatest measure of reward and well-being for both employer and employee, and the full social value of their service to the public must be sought in the successful conduct and full development of the industrial establishment in which they are associated. Intelligent and practical co-operation based upon a mutual recognition of this community of interest constitutes the true basis of sound industrial relations.

X—Government Employment

The State is sovereign and cannot tolerate a divided allegiance on the part of its officers and servants. While the right of government employees, national, State, or municipal, to be heard and to secure consideration and just treatment should be amply safeguarded, the community welfare demands that no combination shall be permitted to prevent or impair the operation of government or of any governmental function.

XI—Public Service Employment

In public service activities the public interest and well-being must be the paramount and controlling consideration. The power of regulation and protection exercised by the State over the corporation should properly extend to the employees in so far as may be necessary to assure the adequate, continuous, and unimpaired operation of public-utility service.

The Committee on Labor of the Associated General Contractors desires the greatest possible publicity and discussion of the foregoing statement. It invites constructive criticism in order to perfect this draft, if necessary.

It is hoped that it may ultimately be widely adopted as the guide for all industrial employment relations.

'RF' ADJUSTABLE-SPEED MOTORS

A second edition of bulletin No. 41021A, superseding bulletin No. 41021 and describing the latest design of RF, Form A, direct-current adjustable-speed motors rated from $\frac{3}{4}$ to 50 intermittent horse-power, comes from the press of the General Electric Co. A compensating winding practically eliminates flux-distortion losses, which may amount to from 5 to 10% in the conventional commutating-pole adjustable-speed motor. To prevent field-distortion the compensating winding is distributed instead of concentrating it at the commutating pole-faces, the magnetizing strength of this winding being equal to and in the direction of magnetization, opposite to that of the armature-winding. The wide and stable commutating zone thus established by a commutating and compensating winding, the latter being concentric to the commutating poles assures practical elimination of commutation troubles even with careless operation.

For ordinary service, driving shapers, slotters, and lathes, a simple type of drum-controller can be used. A more simple type of magnetic control can also be employed, and the motor is particularly suitable for reversing-planer operation, pipe-threading, tapping, or for driving any machine repeating its cycle of operation. Current peaks are limited by the inherent characteristics of the motor. Acceleration from basic speed to high speed may be effected by inserting

the total field resistor in one step. For heavy flywheel-loads special control is necessary. The RF motor is rated on the continuous two-hour basis and, in addition, the main field-coils are designed to withstand, without injury, full potential continuously with the armature at rest.

MINE LOCOMOTIVE HEADLIGHT WITH SPRING SUSPENDED CASE

To withstand the severe conditions under which they are used, the mine-locomotive headlamps placed upon the market by the Westinghouse Electric & Manufacturing Co. have been designed so that the incandescent-lamp case is carried on a spring suspension which adequately protects the filament from breakage due to vibration and jars. The case, which contains the socket and lamp, is entirely suspended

Headlight in Spring-Suspension

from six springs. These springs are placed symmetrically and are in tension. Thus the spring-suspension is equally effective in all directions, assuring the longest possible lamp-life. This type of suspension is very much superior to the usual type employing helical springs in compression. The new Westinghouse headlight responds to the slightest pressure in any direction assuring perfect cushioning, while the usual type requires a considerable force to be exerted in any direction before any movement takes place, which means that only partial cushioning is obtained. The frame, case, and cover of this headlight are made of high-grade cast-iron, heavy enough to withstand a great deal of abuse. As the lens-holder is fitted to the case with a threaded joint and rubber gaskets, the headlight is tightly sealed and, therefore, suitable for use in gaseous mines. Where headlamps are to be operated on circuits of more than 250 volts a resistance is supplied. This resistance is housed in a full cast-iron case of sturdy construction, which is superior to the sheet-steel housing usually furnished.

'Massco Furnaces' is the title of Bulletin No. 63 just issued by the Mine & Smelter Supply Co. It deals with oil-fired appliances. Oil as a fuel in industrial plants has come into widespread use on account of its convenience, ease of control, and in many places its economy. Oil is considered the modern fuel just as electricity is considered the modern power. The advantages of oil as compared with most fuels are, its ease of handling, freedom from dirt, and the complete elimination of ashes. Less labor is required. In addition to these it has a high fuel-value. An intense heat may be quickly secured and when no longer needed fuel-consumption can be immediately stopped by closing the valves. This means the lowering of fuel costs and an increase in the efficiency of operation. Even in places where the cost of coal and oil are comparable, convenience, cleanliness, and ease of control may be the determining factors. Massco oil-burning furnaces are primarily designed for a low-pressure system. Since conditions vary in many localities the company does not, however, recommend one type of burner for every equipment. The kind to be selected depends on local conditions as to power and air facilities.

T. A. RICKARD, . . . Editor

ACCORDING to the revised figures of the Mint, the output of gold in the United States last year was \$60,333,400, which is about \$2,000,000 more than the previous estimate, while that of silver was \$63,533,652, or \$1,500,000 more than the preliminary estimate. In fine ounces the output in 1919 was 2,918,628 of gold and 56,682,445 of silver, the decrease in production being \$8,313,300 for gold and \$11,127,000 for silver. In gold California was first, with a yield of 841,638 ounces, worth \$17,398,200. Colorado was second and Alaska third. Montana produced the most silver, the yield being 15,012,258 ounces, most of which was extracted from ores chiefly valuable for their zinc and copper contents.

ON the occasion of the recent International Mine-Rescue competition at Ladysmith, in British Columbia, the Provincial Minister for Mines, Mr. William Sloan, referred to the unfortunate accident at the Black Diamond mine in Washington as a 'set-back' to mine-rescue work. A report has been issued by the Chief Inspector of Mines for British Columbia, who was sent to make an investigation, and was afforded every facility to do so by the Inspector of Mines of Washington. It appears that a team engaged in practice went into workings that were particularly dangerous without an adequate supply of oxygen. Two members of the first team to enter the mine succumbed and later a member of a team that came to the rescue also lost his life. The members of the two teams had been provided with apparatus that differed in type and functioned variously. The disaster was entirely unnecessary, as there was no need for a team engaged in practice to enter seriously dangerous workings. The lesson taught by the accident is the standardization of mine-rescue equipment. Already steps have been taken by Mr. Sloan to co-operate with the U. S. Bureau of Mines in adopting a uniform apparatus in the coal mines of this continent.

DANIEL GUGGENHEIM made some interesting remarks, which we quoted, just before sailing for Europe. He has something to say on his return. It is cheerful. He says that it is a sad mistake to think that "Europe will not have enormous purchasing power in the future, and that Europe is doomed to ruin". It would be sad indeed if true, and we are glad that Mr. Guggenheim feels confident to the contrary. The countries on the other side are "pulling themselves together in a re-

markable way". That is good news. But, he adds, "we cannot expect an immediate recovery to normal conditions", owing to the after-effects of the War. We are inclined to chortle over the appreciation of the dollar, as compared with European currency, but Mr. Guggenheim says advisedly that "the low exchange-rates will prove of great benefit to the depleted countries so far as getting production under way is concerned. This is particularly true of Germany". In order that the world, of which we are an integral part, may be restored to industrial health, we must give credit to Europe, as Europe used to do to us. "We must sell them goods and allow them time to meet the payments. If we expect those countries to produce, we must supply the materials with which to work." All of which is true, and therefore worth repeating.

INTEREST in Mexican mining is increasing, thanks to the multiple signs of better government. The excellent price for silver is another favorable factor. In London there is a cheerful tone in this part of the mining share-market owing to the handsome earnings being made by the Santa Gertrudis, El Oro, and other well-established enterprises, while the various exploration companies have men in the field looking for new ventures. In New York likewise there is a better feeling toward Mexican mining and the smelting companies are increasing the scope of their operations, which however are still handicapped by the shortage of railroad-cars, so many of them having been destroyed during the years of revolution. Some of the mining and smelting companies are building their own cars and using them under special arrangements with the Government. The new President, General Obregon, has published an article in the current issue of the 'Mexican Review' in which he promises to protect every legitimate interest in the country, whether foreign or domestic. "What Mexico needs at the present time", he says, "is less fighting and more work." We seem to have heard an echo of that remark, or one of which it is itself the echo, in Europe. Even truisms wear a strange solemnity in days like these. Señor Obregon purposes to recognize the foreign debts of Mexico, and to pay interest and principle as they become due, so far as practicable; and to compromise on the over-due interest. He says that the army is to be reduced to 50,000 men, but they will be well paid and well equipped. Mexico needs more laborers and fewer soldiers, which is

a polite way of saying more workers and fewer bandits. Meanwhile we feel confident that the forthcoming administration at Washington will recognize the Obregon government, if such action is not anticipated by President Wilson, as we trust it may be. The United States and Mexico must live on friendly footing and our people must try to understand their southern neighbors. To that end we take pleasure in publishing a timely article on the Mexicans, describing their racial origins and their national traits. This article, as the reader will discover for himself, is written by one who has lived in Mexico and is in a position to understand the people of that country. On account of his frankness, and being a consulting engineer, likely to go to Mexico soon, the author prefers not to disclose his identity.

Industrial Leadership

The current 'Atlantic Monthly' contains an article that ought to be read by the members of the mining profession, because the subject is 'Industrial Leadership and the Manager' and also because the writer of it is Mr. Sam A. Lewisohn, of the firm of Adolf Lewisohn & Sons, honorably prominent in the copper-mining industry. Mr. Lewisohn discusses the efforts made by the managers of big companies to modernize their labor policy by joining a liberal spirit to the striving for efficiency. Indeed, he claims, justly, that efficiency of industrial management is attainable only by a sympathetic attitude toward the men employed. He has no patience for "mere railing against the closed shop and petulant complaining against restricted efficiency". With the growth in the complexity of modern operations and the increased application of technology it has become necessary for the old owner-managers to step aside in favor of engineer-managers, graduated from technical schools. The personal equation remains as of yore; it is still the chief factor in the problem of industrial leadership, but the formula has been complicated by new elements. The creation of a good morale in a mine or mill has been made the study of specialists, known as employment managers, efficiency experts, and welfare workers, but in the end the success of any such systematic effort to promote an *esprit de corps* in the face of labor unrest will depend upon the personality and character of the chief, the resident manager. If the administration is to be unified and consistent, the industrial specialist and the manager must work in harmony, and it is the manager that must strike the dominant note. The manager of a mine discovers only too often that his directors, even engineers who have developed into successful financiers, are out of touch with working conditions, because these have changed since they themselves were in charge of operations. By living in large cities, by associating with a different class, by lack of contact with working-men the head officials of a company lose the ability to understand labor conditions; so that the manager may find himself sometimes out of sympathy with them. They should realize their detachment from the work and give him a free hand. We are hardly surprised to learn from

Mr. Lewisohn that "the evidence is overwhelming that the training that our engineering schools have given does not adequately equip a man to handle so-called 'human engineering' ". Indeed, the term 'human engineering' contravenes the spirit that should inspire any effort to deal justly and fairly with employees. It has been said that the engineer takes pains to learn how to handle the materials used in his work, yet he ignores the need for learning how to handle the basic material of industry, the men themselves. We do not like this way of looking at the problem. The engineer must learn first of all that men are not insensate material like rock or timber; he must have a regard for those imponderables that count for so much in the relations of men to each other. The distinction between the physical and the human factors must be realized, as Mr. Lewisohn says, and he quotes Mr. C. V. Corliss approvingly on this phase of the subject. "We have not yet come to the point where human reactions can be weighed and measured." As a remedy, Mr. Lewisohn suggests that the trustees of technical schools plan their curricula so as to include special instruction "in social economics and the modern technique of handling labor", and follow this with practice-work in the summer vacation, whereby engineering students will be given a chance to work "in industry with the men they will handle in their future careers". That suggests at once the need for a careful choice of instructors, not only economists and sociologists, but men who have had experience in handling men successfully. Some of them have done it well without being able to analyze or describe their own methods, but there are others sufficiently introspective and analytical to be able to give valuable hints to the younger generation. Such men would be worth many books on the subject. Some of them have had but little instruction of an academic sort, but they are schooled in experience and have the ingrained sagacity that comes of an understanding of the most difficult subject in the world—mankind. It may be objected that no academic teaching on such matters is worth much, but, as Mr. Lewisohn says, it will serve to awaken the student's interest and stimulate him to inquire into the technique of the subject. There is a technique; it is a branch of psychology on the one hand and of ethics on the other; and the man versed in it, backed by a kindly disposition and intellectual honesty, can exert a personal influence that is priceless. There is plenty of scope for it, and plenty of opposition; for the professional leaders of the labor-unions do not like experiments of this kind because they "impair the very incentives that hold their national organizations together". So says Mr. Lewisohn. Undoubtedly to the 'walking delegate' type such efforts to mitigate class enmity are anathema. If they succeed his occupation is gone. That is a consummation devoutly to be wished. What is intensely desirable is that the moderate and reasonable elements on the side of capital and the similar elements on the side of labor should find each other, shake hands, and unite in a sincere effort to establish a code of fair dealing between manager and workmen, a

code in which patronage will have no more place than trueulence, and in which the head and the heart will be conjoined to promote the square deal—the democratic ideal.

The Oil-Shale Industry

So much has been said of late concerning the depletion of our national supplies of oil, so many warnings have been issued in official quarters against the present extravagant use of fuel-oil, and so insistent has been the propaganda in favor of the exploitation of our Western shale deposits, that a book on 'The Oil-Shale Industry' is sure to be welcomed at this time. The author is Dr. Victor C. Alderson, who, as President of the Colorado School of Mines, has been under fire. We believe much of the criticism directed against him in that capacity is fully justified, but that does not diminish the possible value of his writing on such a subject as the exploitation of oil-shale. Dr. Alderson is a graduate of Harvard, a clever and well-informed man, therefore we set aside any prejudice, as our readers will do also, we believe, when welcoming a book on a subject of such timely interest. An oil-shale industry cannot be said as yet to exist in the United States, but many small beginnings have been made and the prospects are good for such a development of productive activity as will lead to the actual establishment of a real 'industry'. In its primary stage this branch of mining and chemistry must go through many troubles and disappointments, not because technical difficulties are inherent but because man is prone to err and optimistic promoters are likely to lead simple people into foolishness. One can be much less optimistic than Dr. Alderson and yet appreciate the large quantity of useful data contained in his book; moreover, one may demur to some of his statements and yet feel grateful for the pains he has taken to collect reliable information from so many sources. He announces "the birth of a new industry"; he heralds the dawn of a new era; he proclaims our "well-nigh inexhaustible supply of oil-shale" as the future source of the oil upon which "modern civilization" depends. The statistics indicating the increasing consumption of oil, the depletion of oil-wells, the expansion of automobile manufacture, the insistent demand for oil in various directions, are impressive. He starts well by making the reader realize the importance of the subject he is about to discuss. Then comes a sketch of the nature, origin, and distribution of oil-shale. It contains no oil as such. Oil-shale is mud containing organic matter that has been consolidated into rock, from which petroleum may be extracted by chemical processes. In oil-sand, the objective of an oil-well, the oil is contained in the sand as oil, so that when penetrated by a drill-hole it gushes or can be pumped. In shale the ingredients of oil are undifferentiated; the oil is not separated from the shale until it is subjected to destructive distillation. 'Kerogen' is the name given by the Scots to the organic compounds that produce the petroleum. In Scotland the utilization of oil-shale as a source of oil began in 1850; and it be-

gan in France even earlier. In Australia the exploitation of oil-shale in the Blue Mountains of New South Wales was started in 1865, and a good deal of money has been spent, without much success, however. In the United States oil was won from shale by the Mormons in Utah as early as 1855, but the American supply of well-oil was so abundant and so cheap that the production of oil from rock proved unattractive. Ten years ago the subject was discussed publicly in this country by scientific men, Mr. Ralph Arnold among them, and in 1911 the first claims were located under the placer law. Since then the U. S. Geological Survey has investigated the distribution of shale in the West and has conducted experiments in distillation. Many valuable bulletins on the subject have been issued. Dr. Alderson gives an admirable account of these early researches and industrial adventures. In Scotland the richer shale yielded from 30 to 40 gallons of oil per ton of shale. At the present time a yield of 15 gallons per ton is said to be profitable, but the author's data on this phase of the subject are unsafe. He gives figures for 1909, when the total cost of mining shale and manufacturing oil in Scotland is said to have been \$2.06 per ton and the net profit 83 cents per ton; but much has happened since 1909, more particularly the increased cost of labor and supplies. Later statistics are needed, if they are to be any sort of guide to American operators. However, both the Scottish deposits and the Scottish methods are supposed to be inferior to those of Colorado, Wyoming, and Utah. In the Utah portion of the Uintah basin there are 40 billion tons of shale that will yield "more than a barrel of oil to the ton"; says Dr. Alderson. A barrel is 42 gallons; so that the estimated yield for this enormous tonnage is nearly three times the winning made in Scotland. In Colorado, says our author, there is 2500 square miles of oil-shale. Estimating a thickness of only 12 feet, and assuming that 25% of the rock will be left as pillars, and "counting only on 42 gallons to the ton", there is 1,012,500,000 barrels of crude oil in the Parachute region of the Grand Valley in Colorado. These figures are convincing only in proportion to their accuracy. The book contains many handsome photographs showing "mountains" of shale. These are likewise impressive, on the supposition that they consist of oil-bearing rock. They do not; they contain a layer or layers of oil-shale only, they are not the stupendous masses of valuable material that their titles suggest. This is symptomatic of oil-shale propaganda, we fear. In our eagerness to ascertain the economic value of these deposits, we skim the chapters on 'Mining', 'Retorting and Reduction', and 'Experimental Work', in order to get at the chapter on 'Economic Factors'. There we are told that the cost of "building and equipping a shale plant will run from \$1000 to \$2000 per ton of shale handled". The margin is too generous. A plant having a capacity of 400 tons daily, treating shale that produces a barrel of oil per ton, would produce crude oil at a cost of \$1.85 per ton of shale, or per barrel of oil. So says the author. He puts the cost of mining at \$1.25. This provokes scepti-

cism, as viewed from experience in coal mining. In 1918, according to the U. S. Geological Survey, the output of coal in Colorado was 3.36 tons per man. "In Scotland", says our author, "two men working together produce 8 tons per day at a cost of \$1.25 per ton. . . . Certainly the American miner in our shale beds so easily mined can produce twice that amount". In Utah the cost of run-of-mine coal at the mine is \$3.65; in Colorado it is \$2.75 to \$3.25 per ton. It is assumed, by Dr. Alderson, and by others, that the steam-shovel can be used advantageously in shale deposits; but this is unlikely except in a few favored localities. Shale has not the 'cleat', or cleavage perpendicular to the bedding, that helps so much in coal mining; on the contrary, the drill-holes blasted in shale have a tendency to 'bootleg', that is, explode a thin layer. Moreover, shale is harder to drill than coal; it is a particularly tough rock. These are matters upon which reliable information should be available, enough mining in shale having been done to furnish the requisite data. We hope some of our readers will supply them for publication. Dr. Alderson estimates the cost of retorting at 35 cents; we question whether he has allowed sufficiently for the expense of maintenance. The "amortization, interest, and overhead expenses" at 10 cents are certainly under-stated; this item will be nearer 50 cents, assuming an investment of \$3.50 per ton of annual capacity. On the other hand, crude well-oil in Wyoming is quoted at \$2.50 and in the Mid-Continental field at \$3.15, so that a handsome competitive margin is assured, says our author. The quality of shale-oil, it is claimed, is superior to that from the wells. The minimum capacity of a retorting plant should be 100 tons, to cost \$100,000. "Additional 100-ton units could be installed for \$50,000 each." The minimum size of refinery should yield 400 barrels daily and cost \$350,000. "This also should be regarded as only a starter." The author says that "an investment of \$500,000 is as small as can be safely counted upon to make a single project successful"; evidently he has made scant allowance for the purchase of claims, the opening up of the mine, and the building of a crushing plant. On these matters likewise actual figures, not guesses, should be forthcoming shortly. The tone of the book is indicated by the "opinions" quoted in the last chapter; the author has selected the most optimistic; he ignores those that are less roseate, and in his estimates of yields he sets aside the results of tests made by the U. S. Geological Survey in favor of larger yields based upon the high results from a few tests made by private persons, engaged presumably in the promotion of oil-shale schemes. Throughout the book he assumes the normal yield of Colorado shale at 42 gallons per ton, whereas the figures he himself quotes from the U. S. Geological Survey's bulletins show an average of less than half the barrel, of 42 gallons, of oil per ton of shale. These official results, we may add, correspond closely with those of 300 samples that have been analyzed by private parties known to us. In Utah the Survey gives an average of 23.7 gallons on 83 distillation tests. On page 82 the average yield of the brown

shale in the Parachute Creek district is stated to be 67 gallons per ton. Neither the Survey men nor an independent expert were able to find any shale of such quality in minable thickness; their estimate is just about one-half that based upon the seven samples quoted by Dr. Alderson, on the authority of Mr. J. B. Jones, of Kansas City. In truth, this budding industry, like many others, is endangered by a careless optimism. For instance, Dr. David T. Day in the 'Review of Reviews', contrasting the 'bringing in' of a gusher with the winning of oil from shale, indulges in the following rhetorical confectionery: "Contrast the excitement, the thrill of such sudden richness, with the comparatively tame and stable mining and manufacturing industry by which oil-shale is excavated with a steam-shovel, crushed and thrown into a retort, which slowly, but steadily, yields a stream of oil that can be safely estimated many years in advance, without excitement or speculative risk—an industry which goes forward day and night, regularly, and with nothing to interest the speculator". This assuredly is a gay counting of chickens before they are hatched. When oil-shale mining ceases to "interest the speculator" and becomes the dreary manufacturing process painted by Dr. Day's imagination, it will be the Greek kalends and we shall all go on a perpetual joy-ride. Dr. Day expects to produce shale-oil for less than 50 cents per barrel where conditions are favorable, and for not more than \$1.25 elsewhere. He quotes "the best contractors" as "willing to quarry and crush oil-shale, to the degree suitable for retorting, at a total cost of not to exceed 40 cents per ton, and many venture an estimate of 18 cents per ton". He expects to retort the shale at a cost of 10 to 25 cents per ton. None of this is convincing. A number of shale enterprises are actually in operation, what are their costs? A few real figures are worth a bushel of these cheerful guesses as proffered by gentlemen evidently engaged in the promotion of schemes. What is needed is up-to-date information from engineers actually in charge of shale operations. The subject is worthy of something better than the nebulousities of Messrs. Alderson and Day; it is worthy of scientific treatment. Here we may remark that those engaged in the well-oil industry seem slow to avail themselves of the chances afforded by the deposits of oil-shale. Dr. Day says that this lack of interest is due to the fact that "no oil-producing concern is anxious to increase the oil-supply greatly and thereby disturb market conditions". Tell that to the marines, or whoever now may be the symbol of gullibility! Those directing the existing oil industry have had men in the field investigating the possibilities of exploiting the oil-shale and if they have turned a cold shoulder to the rhapsodies of Dr. Day and others it is only because they are aware of the facts, which are that oil-shale can be benefited profitably under favorable conditions, but that the promoting propaganda now being published is vitiated by an under-statement of cost, and an over-statement of yield, and an expectation of by-products that cannot be won in the present state of the art of oil-refining.

MEXICAN MINERS AT WORK

The Mexicans: Who and What They Are

By An Occasional Contributor

In considering the Mexican question attention must be given to the history and recent racial development of the Mexican people. Constant use of the terms Spanish-America and Latin-America tends to foster the current idea that the Mexican of today bears about the same relation to Spain as the New Englander of the last generation did to England.

Although there is an element of truth in this general belief, the real situation is far different. The fact is, Mexico is not, and never has been, a democracy; it is an oligarchic despotism, more or less feudal in character, masquerading as a republic, and the people are of a race differing, not only from our own but also from the Spanish, in the very fundamentals of their nature. In making this statement I am not referring to the question of mental superiority but to their ideas, ideals, and their mode of thinking, for the average Anglo-Saxon usually requires years of experience to understand them, and some never succeed.

This may be exemplified in the following way: if we consider any ordinary every-day American as influenced by a given set of circumstances, we can predict fairly well what course of action he will take and if he follows one different from that expected we will understand the motives that influenced him, and judge his character accordingly. In the case of the Mexican the average Anglo-Saxon fails utterly, and in the reverse the Mexican succeeds little or no better. The average American going

into Mexico judges the country and the people by his Anglo-Saxon standards (which are by no means the standards of the country), and consequently makes many mistakes. The result is that he is looked upon with contempt by the natives (in their turn judging him by their standards) as ignorant and incapable.

This inability to understand the Mexican is nowhere more clearly shown than by our own government. The Mexican is temperamental, but he is just as much influenced by a plea in the name of the 'square deal' (square deal is a much more accurate translation of *justicia* than the dictionary word 'justice'), as is the American, but his ideas of a square deal are based on principles fundamentally differing from our own and the attempt to judge one system by the standards of the other is not a success.

Many of the books and magazine articles on Mexico have been written after a few weeks trip through the larger cities by people with only a superficial knowledge of the country and are the object of derision to the Mexicans in general, and much regretted by Americans who know Mexico, as well as by Mexicans who know the United States. Many Americans still wax hot under the collar about the views of the United States held by Dickens and Kipling, yet these were geniuses, whereas the ordinary magazine writer is not a genius, nor is he able to understand the mind of a foreign people after a short visit among them.

The reason for this difference in standards lies in the fact that the population of the country is primarily Indian, although there are Spanish and Negro elements and even a slight admixture of Asiatics. In investigating the subject the first thing noticed is the paucity of data and next the inaccuracy of those which are available. Recent census figures are not reliable for a number of reasons some of which will appear from a consideration of the older statistics, but especially because they ignore certain important points. In 1793 Revilla Gigedo, then viceroy of Mexico, attempted a census and did obtain certain figures that have considerable value. Later, about 1808, Navarro, who was at the head of that branch of the government charged with such duties, and, independently, Alexander Humboldt revised the figures, bringing them up to date. From these data the following approximations are obtained as representing the population of Mexico in the year 1808.

Indians	3,676,000
Mestizos	829,000
Mulatos and Zambos	500,000
Negroes	6,000
European Spaniards	15,000
Whites	1,097,000

Total 6,123,000

An explanation of both terms and figures is necessary properly to understand this statement. Under Spanish rule, that is, up to the revolution of 1811-1821, governmental positions, with a few exceptions, were held only by Spaniards of European birth. Presumably equal, but actually next, in rank both socially and legally came the whites (*criollos*), then the castes (*castas*), that is mestizos, mulatos, and zambos, and finally the Indians and Negroes. These classifications carried definite legal rights and obligations as well as social and civil rank. 'Mestizo' was the general term applied to the offspring of Spaniard and Indian, 'mulato' for that of Spaniard and Negro, and 'zambo' for the Negro-Indian union. There was an elaborate technical terminology comprising some thirty or forty names to specify the exact nature and degree of the cross; thus there would be one term if the father was Spanish and the mother Indian and another if the mother was Spanish and the father Indian. A 'quinteron' was a person having one-eighth Indian blood and the remainder Spanish. The child of a Spaniard and a 'quinterona' was legally 'white'.

The term 'creole' (*criollo*) was used to denote persons born in Mexico of pure white parentage, either creole or European-Spanish. The term was not supposed to be applied to those of mixed blood, as it is in this country, but in spite of that it was used by the European-born Spaniards in a somewhat slighting way. The creoles preferred the term 'white', which was considered one of honor and respect, although Humboldt mentions that in his time they preferred the term 'American' (*americanos*).

It is to be noted that the two terms 'white' and 'American', used by us to distinguish the inhabitants of the United States from Mexicans, were formerly used with pride by the Mexicans to distinguish those of the highest social standing. Nor has this wholly disappeared.

To an inhabitant of Spanish-America a citizen of the United States is a 'North-American' or, less politely, a *yanqui*, and I recall that a few years ago I was told by a Mexican creole: "The trouble with many Americans is that they forget there are many white Mexicans." In their own records they class themselves as 'white'; and the real trouble is that the *norte-americano* does not differentiate between the various classes.

There was a sharp distinction between the civil and social rights of whites and those of mixed blood, much to the advantage of the former. Those who had more than seven-eighths white blood were entitled to call themselves 'white', so also were the children of the *conquistadores* and certain privileged Indians. The child of a Spaniard and a woman whose father was Spanish, and whose mother's race was unknown, was also 'white', so naturally the genealogy of many an Indian grandmother got lost. The result was that all who dared to do so called themselves 'white' and many mestizos and Indians obtained legal permission to do so, the formula being, "Let them consider themselves white" (*Que se tengan por blancos*). Humboldt says that every person in Durango claimed to be white and elsewhere I have seen it stated that in Sonora only 251 paid the tax due from all except whites. This was absurd on the face of it.

The number of whites given in the census as 1,097,000 was therefore a gross exaggeration. In 1860 the number of Spaniards of European birth in Mexico was supposed to be about 10,000 and in Navarro's estimate, immediately before the revolution against Spain, it was 15,000. Revilla Gigedo's figures were 7904 in 1793, of which 2335 were in Mexico City, but of these only 217 were women. Bancroft explains the small number of women by saying that, owing to the hardships encountered, very few Spanish women came to Mexico. Where then was there any opportunity for breeding a million pure-blooded whites? Practically, the term 'white' as used today means any one who is not pure Indian or Negro.

Another thing to be noted is the amount of Negro blood. The figures given are not exaggerated; indeed, they indicate a rapid absorption of a still greater number. Cortez was authorized to import Negro slaves, one of the first licenses being for one lot of 4000. In 1635 Thomas Gage mentions the large number of mulatos and the wealth displayed by the mulato women of Mexico City. As an example of the large numbers throughout the country, he says that on the ranch of the Dominican fathers near Puebla there were "200 negroes, and women and children besides". About the middle of the 18th century Garcia Palaez made an estimate quoted by William Bollaert as follows:

Whites	450,000
Indians	1,350,000
Negroes	500,000
Mestizos	1,500,000
Mulatos	600,000
Zambos	300,000

He adds that it is probable the number of Indians includes only those paying the tribute. Note that there were more Negroes than whites.

About that time the Government set itself against the slave traffic, so that the figures of Navarro show the effective absorption during the next sixty years. During the last hundred years this absorption has become complete, so that the Negro, mulato, and zambo have disappeared.

Today the population of Mexico is probably about 14,000,000, of whom some 6,000,000 are more or less pure-blooded Indians, still speaking their own languages, the remainder being of white and mixed blood. I believe the census shows over two million whites, but one of the enumerators told me that the figures are of little value. The classification 'white' rests on the individual's own

700 tribes are classified according to language into the following groups:

Apache (Athapaskan)	
Zapotec	600,000
Yuman	
Huavian	
Otomian	700,000
Mayan	400,000
Nahuan	
Piman	
Shoshone	
Aztec	1,700,000
Totonac	
Tarascan	
Zoquian	
Serian	200

The figures are from estimates made several years ago by the U. S. Bureau of Ethnology and are probably much

A BULL-FIGHTER

A 'SPORT'

statement, which is biased. My own opinion is that the number of genuine pure whites is less than 2% of the total.

The Indian forms the greatly predominating portion of the mixture. When Cortez discovered the country he found it inhabited by a large number of independent tribes, speaking different languages. Most of these tribes may still be identified; Mexican ethnologists have traced and classified about 700 of them, although the dividing lines are now blurred, and in many cases have disappeared, but all of them, with the probable exception of the Otomis and Seris, are of the same racial stock. These

too low at the present time, especially the Mayan. The blanks in the table are caused by lack of data at the time of writing.

The close relationship between these races and the Indians of our own country is shown by the names in the list. The Navajos, Zunis, and similar tribes are just as closely related. There is a Navajoa tribe in Sonora that makes, or did a few years ago, fine blankets of the Navajo type, and I believe the similarity in name and occupation is more than a coincidence. It will be noted that the Yaqui tribe, of which so much is read in the newspapers, does not appear in the above list. The reason is

that it is simply a branch of the Nahuatl. The Seris are included in spite of their small number because they seem to be the remnant of an aboriginal people, their language being distinct from all others. They are the inhabitants of Tiburón island, which, every few years, is discovered and explored by a few daring adventurers, at the risk of their lives and a few columns of print. Any person desirous of being the first white man to tread the soil of that unknown land is hereby referred to the reports of the Bureau of Ethnology, written about 25 years ago, in which he can find full directions, including maps of the island, mode of reaching it, sources of food and water, and all other necessary information, including photographs of the islanders and the interiors of some of their dwellings.

Some of the other well-known tribes whose names will be recognized are the Papagos, Opotós, Tarahumares, Tepehuanes, Huastecas, and Tlascalans.

At the time of the conquest Mexico, like all Gaul, was divided into three parts, northern, central, and southern. Northern Mexico comprised everything north of what is now Aguas Calientes. The district is mountainous or sterile, except the coastal region and a few well-watered valleys. It was inhabited by various Indian tribes of the same race and stage of development as those of the western and south-western part of the United States. These tribes were completely independent and were classed by the Aztecs under a general term meaning 'the barbarians'.

Southern Mexico was held by the Mayas, the remnant of a once powerful nation which had apparently ruled the whole country from the tropic of Cancer to the isthmus of Panama in some former epoch, but had degenerated as the result of epidemics and internal dissensions. Their holdings were mainly tropical. From personal observation of some of the Mexican antiquities, I believe that there was a definite relation between the Mayas and the Egyptians of the early dynasties, long before the Christian era.

Central Mexico was dominated by the Aztecs, but there were still independent tribes and warfare was constant. The Aztecs, Zapotecs, and Mayas were far ahead of the remainder in the scale of civilization, but much below what Prescott would have one believe. Their land was partly tropical valleys and partly temperate tablelands.

There is no reliable information available as to the population of the country at that time, but after reading the various recorded guesses and seeing the country and people of today, and some of the remains of the former civilization I would say that five to seven million would be a fair estimate, although evidence can be adduced that it could not have reached four millions, and other testimony, equally strong, indicates that it may have exceeded 12 millions. If I had to choose between these two estimates, I would prefer the smaller.

History apparently records no religion so fierce and so bloody as that of the Aztecs. Clavigero quotes authorities to the effect that in the coronation-year, alone, of Ahuitzotl, the number of human sacrifices reached the awful total of 72,000 and that the average number per

annum in Mexico City alone was 20,000. These figures are undoubtedly exaggerations, but equally undoubtedly the real number must have been very large.

In addition to this there was religious cannibalism, that is, the bodies of the victims were eaten according to prescribed ceremonial. Cortez in his official dispatches to the King of Spain says: "Thus by means of the ambuscade more than 1500 of the enemy were slain and that night our allies were well supplied for their supper as they took the bodies of the slain and cut them up for food". (Folsom's translation, 1843 edition.)

The numerous wars were largely for the purpose of obtaining victims, the main object of the Aztec warrior being not to kill but to capture his enemy alive for subsequent use as a sacrificial offering, the subjugation of the neighboring tribes being only of secondary consideration with the Aztec rulers. This kept up a continual state of war and it was by taking advantage of the tribal hatreds thus engendered that Cortez conquered, rather than by force of arms.

It was this Aztec-Zapotec civilization that was dominant in Mexico, and it is to be remembered that the descendants of these Indians are prominent in Mexican affairs of today, and that until about fifty years ago there was no attempt made to educate them. In vice-regal days the clergy as far as possible destroyed all knowledge of the Indian civilization and the secular government prohibited their education in the white man's standards.

Their social system was distinctly feudal. The Emperor, so-called, was a great feudal lord (*cacique*) who was supported by tributary *caciques* and so on down the scale, the smaller ones having only a few retainers, perhaps only the members of their own family. The family was the unit, not the individual, the individual being always dependent upon some chief or greater chief to whom he rendered obedience, tribute, and support, and by whom he was protected. The relationship was one of mutual service, not slavery; it was patriarchal in nature, although leadership did not necessarily pass from father to son. Land could be held by individuals, but was mainly held in common, and one of the reasons for Zapatism is the demand for the return of the community-property belonging to the villages.

In the north-eastern part of the State of Puebla there is a remnant of the Aztec tribe, off the beaten track and comparatively little affected by the outside world. They still speak the old Aztec tongue and are ruled by their own customs rather than Mexican law. The villages hold community-land and the families hold their land in common. Half-breeds are not allowed to take part in tribal affairs. If anyone desires to employ a few laborers, the correct way is to send word to the chief, who will dispatch an available sub-chief controlling the requisite numbers. Under the guise of saints'-days they still celebrate the old and easily recognizable corn and sun dances, and it is even hinted that in the mountains they celebrate other old rites, not so harmless.

This, then, is where the fundamental difference between the American and Mexican comes in. The Anglo-Saxon is fundamentally individualistic and democratic,

AN INDIAN CAMP

A GROUP OF REVOLUTIONISTS, SUPPORTERS OF MADERO

and always has been in spite of feudal branches grafted on the democratic stock. The Mexican, on the other hand, belongs fundamentally to a feudal patriarchal system, even to the extent of recognizing the justice of vicarious punishment.

The second difference is the regard for human life. It is not to be believed that the bloody customs of the old Aztec religion are without effect on the character of the Mexican of today. He shows no hesitancy in killing if circumstances seem to him to require it.

These native characteristics were developed and strengthened by the conquest. The Spanish government, basing its action on the theory that the Indians were barbarians requiring care and protection, decided that in recognition of public services certain Spaniards should be given the government of a village or tribe of Indians, as the case might be. In accord with the spirit of the times, they were to be allowed to levy a tax, either in produce or services, to pay the expenses of the Government and to provide a suitable salary for the Governor. These were the *encomiendas*; they were hereditary, and supposed to indicate the establishment of a feudal system. In practice, the Indians became slaves. Las Casas gives a terrible picture of the decrease in population resulting from the Spanish rule and, although his figures are undoubtedly exaggerated, the entire disappearance of the aboriginal population of Cuba and Santo Domingo is proof enough of the evil results. To stop this, slaves from Africa were introduced into the country, and slavery was not abolished until the revolution commencing in 1811, but, be it noted, slavery was abolished fifty years earlier than in the United States. The theory of government in Mexico during the Spanish rule was ahead of the times even if the practice was far behind.

After the conquest the Spaniards at once attempted to take possession of northern Mexico, and sent out colonies consisting mainly of allies, usually Tlascalans, with a few Spaniards in charge, to settle the country, but they were necessarily few and widely scattered. The conditions in the extreme South was somewhat similar. In the attempt to rule this vast domain, much of which was sparsely settled, it is not surprising that revolts and raids ensued. Some tribes never did yield until within comparatively recent years. The Mayas, I believe, did not consider themselves as part of Mexico until a treaty was made within the last fifteen years. It has been said that the only years of peace in the four hundred since the conquest were those during the administration of Diaz.

Northern Mexico is dry and unproductive; the land must be worked in large units with expensive irrigation in order to be profitable. Except in a few favored spots 'forty acres and a mule' are of no value at all. Naturally the small farmer could neither develop a farm nor protect it from Indian raids and bandits when established, so the result was that agriculture was mainly in the hands of the leaders who improved large ranches with walled fortress-like haciendas to protect their families and dependents. Many still remain with their loopholed towers on the alternate corners and a little village within. The individual could not stand alone, so the combination of

the feudal and patriarchal systems persisted. Then came the revolution of 1811 and the wiping out of class distinctions, but it could not wipe out the material conditions, nor the heritage of blood and feudalism.

This is a rough outline of the background of the present Mexican status. What then, is the Mexican of today? Taken as a whole he may be said to be a cross consisting of about 83% Indian, 12% Spanish, and 5% Negro, with a strong trace of Asiatic, but the melting process is by no means complete nor is it uniform. In northern Mexico, for example, the mining engineer in the mountains who employs a lot of peons probably has a group that is 95% or more Indian. Villa's forces, excluding adventurers from outside, are probably 90% of the same race as that cooped up on the Navajo, Apache, and Pima reservations. On the other hand, the manufacturer in the city is likely to have a force that is 15 to 20% white blood. In Yucatan, or Oaxaca, or Chiapas, the peons may be pure Indian.

The percentage of white blood increases with rank in the social scale until in a few families it is pure, although I believe this to be true in less than 10% of the cases so reported in the last census, otherwise the early Spanish women must have been extraordinarily prolific. Practically never will a man with predominating white blood be found among the peons. On the other hand, men with pure or predominating Indian blood do often appear among the most important men of the country. Juarez was a Zapotec, so were Diaz and Huerta; and there is absolutely no question about the ability of the first two, at least. Humboldt mentions an Indian millionaire over a hundred years ago. The large number of Zapotecs and Tarascans in public life is proverbial. The great ranch-owners are frequently white though more often there is a trace of color, since marriage with those of mixed blood is not regarded as it was before the revolution against Spain.

The peon, in the mass, therefore may be said to have at least 90% Indian blood, 6% Spanish, and 4% Negro, most of the latter being in the peons of Vera Cruz, Puebla, and other central and southern States. He is superstitious, ignorant, thoughtless, and improvident, kind but easily excited, and then cruel both to people and animals, usually insufficiently nourished, and possessed of a well developed love for the *tierra*, with strong family and tribal loyalty. He is a faithful and steady worker under a just and strong boss who understands him, but lazy and worthless under a weak or unjust supervisor. When properly instructed, well fed, and well managed, he is an efficient worker and a good artisan, and soon identifies himself with the family or concern for which he works. His mentality is low, but how much of that is due to lack of education, insufficient and improper food, and disease, I am not prepared to say—certainly a great deal.

It is a common saying that the Mexicans are thieves—and they are; but the statement must be greatly modified because in some ways and under some circumstances they are thoroughly honest and trustworthy. As an example of the working of the peon mind, I mention Romolo. I

was in a small mining camp and had engaged Romolo as a servant. His duties were to look after my room, do the marketing, milk the cow, and attend to the usual odds and ends. One day I went away for the week-end and on my return was told that every house in camp had been robbed. I hurried to my room and found, as expected, that everything of value was gone. Romolo showed up in due season and I told him that the thieves had taken all my belongings. "No, Señor," said Romolo, "I had a hunch that there was going to be a robbery and took all your things and hid them out in the brush"; and sure enough every last one was brought back. Now that was honesty as he saw it. He could not 'tell on' the members of his circle who did the stealing, nor could he permit them to steal my things; nor did it concern him that they robbed my friends. I have known a banker to send \$5000 in bills by a peon on a ten-days tramp over the mountains alone and the peon's wages were about 35 cents per day, yet the money was delivered to me in due course.

With his heritage of ignorance, feudalism, and serfdom the peon needs and expects a *patron*, and I think that it will require several generations to overcome that condition. He is not fit for democratic government as we know it and it seems that it will take at least three generations of education for him to qualify.

As a people we endorsed Madero's cry for universal suffrage in Mexico, but in our own country the Indian has been placed on reservations under the tutelage of the Government, and Indian schools have been established, yet even in these days of Bolshevism I doubt if many people can be found who would advocate giving a controlling vote to the Apache, Sioux, Navajo, Shoshone, Zuni, Moqui, and Yuma Indians, yet that would be precisely the condition in Mexico under a purely democratic government enforced in accordance with the law. I mention these particular tribes because of their direct relation in language, blood, and custom to those in Mexico.

The Spanish government attempted to rule five million Indians by keeping them in ignorance and subjection, using for the purpose a few thousand Spanish-born agents, aided by a favored class which was united as against the divided Indian tribes. The revolution of 1811 was successful against this state of affairs not because of the combining of the Indians, but because the favored class of white creoles was jealous of the authority and prestige of the Spaniard. The first ruler after the revolution was a creole, Iturbide. As soon as the Spaniards had been overcome, the creoles expected to rule the country, but their caste itself was too heterogeneous and did not hold together, owing to the presence of strong mestizo and Indian elements. The situation was somewhat as it would be in the Southern States if there were seven blacks for every white man and a few favored blacks and mulatos were classified as white. It must be remembered, first and last, that the Spaniards never did control the whole country. Indian raids and robberies were numerous, particularly in the northern part, and banditry was common even in the parts that the Government did control. After the break-up of the Spanish government and the failure of co-operation and unity

among the whites, one party after another seized the power, but was never strong enough to accomplish anything definite. Lempriere, writing in 1859, says: "In 38 years the country has had 36 different forms of government and 72 individuals have figured as chief executives."

Mme. Calderon de la Barca, writing during the early years of this period, mentions the necessity for armed escorts with the stages and of having had prominent bandits pointed out to her on the city streets. She describes a Governor's ball and mentions that the gentlemen put on their pistols, as a matter of course, before leaving. Lempriere, in 1862, says, "Life is utterly insecure in Sonora, Sinaloa, Chihuahua, Coahuila, Durango, etc",

A ROPE-MAKER

and "the ransom system is coming more and more in vogue . . . The murderers of Yorke, the young American attaché, are perfectly well ascertained citizens resident in Tepyahualco . . . The civil power has no force . . . Mr. Mathew's residence in Mexico was forcibly taken possession of on the 16th of November, 1860, by General Lagarde under a pretence, the falsehood and absurdity of which must be notorious, that a deposit of arms was concealed." "A force of twenty men made a descent on the house of Mr. Beale . . . They told him he was a foreigner and as such their enemy, and fell upon him and literally cut him to pieces." "Two of the public stages arrived in this city with the passengers stark naked." "The army is a nursery for highwaymen." "The lists of claims for outrages on British subjects pre-

sent such a frightful catalogue of murder and robbery that, except vouched for on the most solemn and sure grounds, would be incredible. . . . Some small show of inquiry, and incessant persecution of witnesses, and never-ending expenses, ending in a mockery of investigation and total impunity of crime, are generally the utmost attained." In another place: "Usually after all his trouble and expense [the injured party] has to pay the prisoner a sum of money to compromise an attack on his [the prisoner's] unblemished character".*

This sounds like an extract from one of Senator Fall's speeches. In other words, the present condition of Mexico is normal; the period of safety and industrial development under Diaz was abnormal.

After some twenty years experience in Mexico, my opinion is that Diaz was driven out as a result of the educational system he established. The Spanish viceregal system was certainly founded on the ignorance of the Indians. The Church was an essential part of the Spanish state in Mexico; after the revolution it still retained its power, and did not attempt in any way to educate the Indian except as to his duties to the Church. The school as a means of secular education dates practically from the time of Diaz, and while the system of public schools which he established was far from what is considered ideal in the United States it was a vast improvement over anything preceding it. By 1910 a generation had arisen that knew the rights to which they were entitled under the law, but still did not know how to use those rights with discretion, and failing to obtain them because of their neglect to observe at the same time the maxim of Juarez, "Peace is the due regard for the rights of others", caused the downfall of the Diaz administration. If Diaz could have had his health and strength for twenty years longer, I believe Mexico would have attained a well-established liberal government in peace and quiet. In 1910 practically all the young men of city and town could read and write, but during the last few years most of the schools have been closed except in the larger cities. Children who were of school age in 1910 must now work to earn a living and the generation now growing up knows nothing but revolutions and their attendant troubles.

Those who state that there never was an honest election in the time of Diaz are perfectly correct. There never has been one in Mexico. Madero's election was a farce and Carranza's rested on his own *ipse dixit*, but, by the same token, how many elections have there been in Mississippi that have lived up to the spirit of the Fifteenth Amendment? Can South Carolina or Florida throw the first stone? How can any man in Mexico on whom the welfare of the country depends trust the election to a majority of uneducated and ignorant Indians? I do not except the recent election. That it represents the wish of the majority of those now in control of Mexican affairs, I grant; but I doubt if 2% of the population voted, and I am sure that not more than a quarter of those had the slightest idea of what they were doing.

*Mexican law permits a suit of damages against the complainant in case of acquittal.

I am equally sure that if any large number had wished to vote against Obregon they would have had considerable difficulty in getting their votes counted without the usual preliminary discussion with Mauser rifles.

I give an example: In 1909 I was traveling in southwestern Chihuahua, a hundred miles or so from the nearest railroad, and stopped at a small mountain ranch to get provisions. I had already noticed throughout the country a strong feeling against Diaz, which the rancher evidently shared. He was above the average in intelligence, so I asked him why the feeling existed. His reply, freely translated, was as follows: "Well, Diaz keeps peace all over the country, but in the old times there was lots of fighting and when there was fighting (*guerra*) the pickings were good". This sounds to me a good deal like Bolshevism, but he was one of the voters for whom Madero was crying "universal suffrage". Any government in Mexico must reckon with this condition.

Prior to the coming of the Spaniards there was no government of Mexico as such, because, as previously stated, the country was inhabited by a considerable number of independent Indian nations. After the conquest the history of the government may be divided into three periods:

The first period, from the conquest until the end of the revolution against Spain in 1821, consisted of the government of a number of subjugated Indian tribes by a few thousand agents of the conquering nation. This period was marked by the education of the dominant race only, and the form of government failed because the favored class finally recognized its own power and seized the government for itself.

The second period lasted until the French intervention in 1862. In this case a ruling white caste attempted to govern a large mixed caste and a number of more or less closely related Indian tribes. There was education of the dominant groups only. The system failed because of a lack of solidarity in the ruling caste and its failure to recognize the nature and strength of the subordinate castes. It is to be noted that two of the important leaders who overthrew it were pure-blooded Indians.

From 1862 to 1867 there was an interregnum, due to an attempt to re-establish a combination of the first two systems by aid of the French. It failed, because it possessed the bad points of both.

The third period, from 1867 to the fall of Diaz, represented the governing of a number of Indian races by a ruling caste, consisting of a dominant clique mainly of the white race, and a subordinate larger group mainly of mixed blood, membership being dependent on money, education, or political control. This period was marked by an attempt to establish general education. It failed because of insufficient recognition of the power of the awakening subordinate caste, which had not yet acquired sufficient knowledge to use its power justly or harmoniously.

The year 1911 was marked by an ill-judged attempt to establish a government of the people by universal suffrage. It was a complete failure, because the general education was as yet insufficient to weld the heterogen-

eous elements into a unified nation. The failure has resulted in the re-establishment of the third form of government in its earliest stage. If that attempt had been postponed 20 years, I believe that revolution would not have been necessary.

The recent revolution and election introduce no new element. Obregon is a creole, that is, he is of Spanish descent, which in itself is a source of weakness. Apparently the Indians best understand the Indians and there is more than a suggestion of this truth in the fact that Juarez, Diaz, and Huerta died in their beds while Iturbide, Madero, and Carranza (creoles all) died from the common over-dose of lead. Obregon, however, has shown marked ability in handling the Indians of the North, and now that he is president and resident in Mexico City he may succeed with the Indians of the South, but there has been little love lost between the two regions and he is between the devil of jealousy if he surrounds himself with old friends and the deep sea of uncertainty if he abandons them for new ones. He has, however, shown himself able to profit by the experiences of his predecessors, and our people at Washington likewise are learning, if somewhat slowly. The death of Carranza will be forgotten, unlike that of Madero; the outlook is now the brightest it has been since Madero started his revolution; nevertheless the elements of weakness are there. Time alone will tell whether Obregon has the requisite strength and wisdom.

Once more I quote from Lempriere, who, sixty years ago, wrote:

"The merciful hand of Providence has bestowed on the Mexicans a magnificent land, abounding in resources of all kinds—a land where none ought to be poor, and where misery ought to be unknown. . . . One thing alone is wanting, that is a government—and the absence of this mars all the other magnificent advantages."

Ontario's Mining Industry in 1920

Returns received by the Ontario Department of Mines for the six months ending June 30, 1920, are tabulated below, and for purposes of comparison the quantities are given for the corresponding period in 1919. Tons throughout are short tons of 2000 lb.

Product	1920 to July 1	1919 to July 1
Gold, ounces	277,656	231,729
Silver, ounces	4,474,322	5,744,172
Platinum metals, ounces	134.45	30.08
Cobalt (metallic), pounds	113,239	59,337
Nickel (metallic), pounds	4,854,979	5,147,745
Nickel oxide, pounds	3,491,544	5,503
Cobalt oxide, pounds	388,318	202,912
Other cobalt compounds, pounds	1,417	26,289
Nickel sulphate and carbonate, pounds	159,183	133,732
Lead, pig, pounds	749,820	1,481,204
Copper sulphate, pounds	89,939
Copper, blister, pounds	2,918,153	3,080,492
Nickel in matte exported, tons	9,527	7,072
Copper in matte exported, tons	4,434	4,341
Iron ore exported, tons	2,189	5,804
Iron, pig, tons	28,771	24,095

During the half year 1445 tons of ore, 581 of concentrate, and 1185 tons of residue were treated in the southern Ontario refineries situated at Thorold, Deloro, and Welland for a recovery of 1,477,490 oz. of silver in

addition to arsenic, metallic nickel, metallic cobalt, and compounds of these last mentioned metals. The companies operating were the Coniagas Reduction Co., Deloro Smelting & Refining Co., and Metals Chemical, Ltd. The last mentioned operated for the first three months of the year only, after which the plant was taken over by Ontario Smelters & Refiners, Ltd. Alterations in plant and process were made, which prevented production during the second quarter of the year. This new company also owns the plant at Chippawa formerly operated by the Standard Smelting & Refining Co. Copper sulphate was recovered from residues by one of the companies. Only 203,713 lb. of metallic nickel and 15,384 lb. of oxide were marketed.

During the half year 627,681 tons of nickel-copper ore was raised and 520,705 tons smelted, the total output of nickel-copper matte being 28,365 tons containing 15,030 tons of nickel and 7705 tons of copper. The British America Nickel Corporation and the International Nickel Co. of Canada worked the Murray and Creighton mines, while the Mond Nickel Co. raised ore from the Garson, Levack, Bruce, Worthington, and Victoria No. 1.

As regards shipments of matte, 7944 tons went to Canadian refineries at Port Colborne, Ontario, and Deschenes, Quebec, 16,323 tons to the United States, and 1123 tons to Wales. During the period the new electrolytic refinery at Deschenes commenced operations and had 1185 tons of matte in process on June 30, although no refined metal was ready for market at that date. The new plant which permits recovery of metals of the platinum group in pure form is reported to be working very satisfactorily as is also the smelter at Nickelton, one mile from the Murray mine, where the ore is smelted direct without preliminary roasting. In addition to metallic nickel, nickel oxide, and blister-copper, there was a by-product recovery at Port Colborne of the precious metals gold, silver, platinum, palladium, rhodium, ruthenium, osmium, and iridium. There was also a small recovery of copper in the United States from Ontario silver ores.

The entire output of pig-lead came from the mine and smelter near Galetta on the Ottawa river operated by the Kingdon Mining, Smelting & Manufacturing Co. The product was consigned to the James Robertson Co., Ltd., of Montreal, manufacturers of plumbing supplies. There is a small recovery of lead from the silver ores of Cobalt treated in the United States refineries, returns of which are received only at the end of the calendar year.

JAPAN in 1918 imported ferro-manganese to the amount of 1,697,280 lb., valued at \$203,452, of which Australia furnished 1,132,800 lb. and Great Britain 564,480 lb. The principal countries to which Japanese manganese is exported are the United States, Great Britain, France, and China. In 1918 Japan's exports to these countries aggregated 5,229,864 lb., valued at \$176,120, and in 1919 they amounted to 6,158,932, valued at \$237,365. The present price of ferro-manganese is \$200 per ton for high-grade.

Notes on Routine Assaying at the Globe & Phoenix Mine, Southern Rhodesia

By H. R. EDMANDS

*As some innovations in assay-practice have been made here, a short description of the methods adopted may be of interest.

The ore itself presents no particular difficulties; it contains stibnite, averaging perhaps 2%, and although much of the gold is fairly fine, coarse gold is also frequently present. Some 1600 to 1800 assays are made per month, and a day's run seldom much exceeds 100.

PREPARATION OF SAMPLES. In dealing with the samples received, the chief difficulties in getting representative portions for assay are as under:

CRUSHING MINE SAMPLES BEFORE QUARTERING. Just how far crushing should be carried depends, of course, on the even distribution, or otherwise, of the gold in the ore. Bearing in mind that a piece of ore 1-in. cube on being reduced to $\frac{1}{8}$ -in. cubes would be divided into 512 fragments, as against only 64 if reduced to $\frac{1}{4}$ -in. cubes, the importance of fine crushing at this stage is evident. Coarse rolls following a breaker would in many cases be advisable.

SEGREGATION OF VALUES IN FINE CRUSHING AND SCREENING. The more brittle or softer portions of the ore, being the first to be crushed, will be separated from the harder portions (carrying different values) by screening during crushing. A similar segregation occurs with disc-pulverizers, and very thorough mixing of the ground product is required to get accurate results.

COARSE GOLD will obviously cause discrepancies in duplicate assays. Some consideration of the law of averages affecting this is not without interest.

Assuming that 20-dwt. ore is dealt with, that two assay-tons are taken, and that the gold and quartz exist in spheres of equal size, then, if Poisson's law be applied it will be seen that if these spheres be $\frac{1}{60}$ in. diam., the maximum error will be 39 dwt., and the mean error 9.2 dwt.

If spheres be $\frac{1}{100}$ in. diam., the maximum and mean errors will be 16 dwt. and 4.5 dwt.; if $\frac{1}{200}$ in., the errors will be 5.6 and 1.6 dwt., while $\frac{1}{400}$ -in. spheres would give maximum and mean errors of 2 dwt. and 0.56 dwt. respectively.

Doubling the amount taken for assay does not halve the error, which varies inversely as the square root of the weight of sample taken.

Although on crushing a sample to pass, say, a 60-mesh screen, the greater portion of the gold would be very much smaller, yet if the crushing is effected with frequent screening or by means of a disc-pulverizer, which

acts much as does a screen, the gold will not be so finely divided as it would be if the sample were crushed, say, in a ball-mill without removing any portion until the whole had attained the required degree of fineness. In the last case attrition of gold continues throughout the grinding, in the former, some of the coarser gold is removed, when it will just pass the screen or escape between the plates of the pulverizer.

More concordant results would be expected from crushing in ball-mills, and this is borne out by practice.

BALL-MILLS FOR SAMPLE GRINDING. To eliminate as far as possible some of the sources of error alluded to, I designed a mill capable of taking the product of the breaker and reducing it at one operation to practically any degree of fineness required, this being regulated by the time of grinding and the weight of balls used.

The mills are made of cast-iron with two compartments separated by a vertical partition through the centre, perpendicular to the axis. Each compartment takes a sample of 600 or 800 gm. Its inside diameter is 11 in., each compartment being $3\frac{1}{2}$ in. wide. Two 3-in. balls are used in each compartment. The mill is driven at 70 r.p.m. by $1\frac{1}{2}$ -in. belting, direct from 2-in. counter-shaft, without pulleys, and the belt runs over the centre of the mill, which is slightly crowned.

Excluding the cost of the pattern, the mills were made, at the mine, for a little under £5 each.

A timber frame of simple construction holds the mills, the bearings are of native hardwood, open at the top, so that the mills can be lifted in and out by two hooks. Each compartment of the mill is opened by one nut, and its contents emptied into a pan. It is then cleaned by compressed air. Eight such mills, taking 16 samples, are in use.

The mills are cheap, readily accessible for cleaning, and wear is inconsiderable, very much less than with disc-pulverizers; also as the wear is even, it does not affect the efficiency of the mill, which is not the case with disc-pulverizers.

The final product is perfectly mixed, and, no screening being required, is ready for assay.

A 600 or 700-gm. sample that just passes a screen with $\frac{3}{8}$ -in. openings will, after $1\frac{1}{2}$ hours grinding, give a product averaging

	On 60-mesh.....	Nil
Through 60-mesh " 100 "	0.5 %
" 100 " " 150 "	6.0 "
" 150 "	93.5 "

*From 'The Journal of the Chemical, Metallurgical and Mining Society of South Africa'. April 1920.

vantages outweigh this drawback, at least with this ore.

BATTERY-DISCHARGE (SCREEN) SAMPLES. Lime is added to promote settlement, the clear water decanted, and the thick pulp well mixed. The portion taken for assay has most of its remaining water removed by an air-pressure filter, after which it can be quickly dried. This type of filter is quicker than, and preferable to, a vacuum-filter, except when the cake requires washing, for which it is unsuitable, cracks being apt to form and cause channeling. The dried sample is ground for two hours in the ball-mill, when all passes a 100-mesh sieve, and 98% passes a 150-mesh sieve. Fine grinding is essential to get concordant results.

REDUCTION SAMPLES. These do not require fine grinding, all but the finest gold having been removed by amalgamation.

Reduction samples, containing dissolved gold, are

both wholly and in part, has been tried, but with unsatisfactory results.

MIXING ORE AND FLUX. This is effected by shaking in a large glass with a metal cover, to which is cemented soft sheet rubber. Mixing is more thorough and quicker than by the older method of rolling on glazed paper.

ASSAY-FURNACE. The coke-fired Cornish furnaces, formerly in use, have been replaced by a reverberatory furnace shown in the diagram.

This type of furnace I previously adopted in Western Australia for burning wood, and it follows, I believe, the general lines of those used on the Rand. Wood, wood and coal, and coal alone have been used, the first being much the cheapest in Western Australia, and the last, the cheapest here.

Special features are the abrupt lowering of the top arch just behind the firebridge, deflecting the flame onto

REVERBERATORY ASSAY-FURNACE

Scale: 1 in. = 4 ft.

treated as follows: The dissolved gold is precipitated, usually by adding cuprous chloride dissolved in brine, to the pulp, and acidifying with sulphuric acid. The pulp is then filtered in the air-pressure filter and dried. This is not only much quicker than drying without filtration, but gives more accurate results. If the excess of barren solution be not removed by filtration, some of the gold is apt to re-dissolve on heating, and to form an enriched hard scale adhering firmly to the dish. For richer solutions I have found the error, presumably from this cause, to be quite important. In cases where much sulphocyanide is present, and precipitation by a cuprous salt is imperfect, an emulsion of finely ground charcoal should be substituted, or used in conjunction with the cuprous salt, by which perfect precipitation is obtained.

FLUXING. The substitution of fluorspar for borax,

the front row of pots; the hearth is not level, but rises gently from bridge to flue, obviating the danger of pots falling backward; the hearth is covered with a layer of sand, or, preferably, of sifted earth, which absorbs any slag spilled.

The furnace will take a charge of about 56 pots, usually 6 or 8 Js, and the remainder Gs and Fs; the heat is uniform, and the pots last considerably longer than with Cornish furnaces. During fusion the damper is nearly closed, and a somewhat reducing atmosphere is maintained.

Two charges of pots generally complete the day's work, after which the same furnace, without a muffle, is used for cupellation.

CUPELLATION is effected as follows: Bricks are placed on the hearth of the furnace to support wrought-iron

plates, each carrying about 25 cupels. The cupels are charged with lead buttons while they are cold. A good fire is made, and the damper opened rather more than when the pots are in. The atmosphere is reducing at first, but soon becomes oxidizing and cupellation proceeds steadily. Many checks have been made by re-cupelling prills of parted gold, but no loss of weight could be detected.

T. Kirke Rose has shown (Inst. M. & M. Bull. 174, March 13, 1919) that gold is not readily volatilized either in a reducing or an oxidizing atmosphere, and that losses are much greater when exposed to alternate reducing and oxidizing conditions. Such alternations occur here, but at an early stage when the gold is well protected by lead, which probably accounts for the absence of appreciable gold losses.

Over 100 cupels can be taken in one charge, and so far as I know, this system of cupelling without a muffle is unique in assaying. It, however, should be noted that all assays here are parted; whether it would answer as well in cases where the gold prills are weighed direct I cannot say from experience.

CUPELS. For the past 12 months these have been made from old used cupels, re-ground in a ball-mill. The absorbent power of these cupels is excellent, and they are in every way satisfactory.

Cement, and mixtures of cement and mabor, were previously tried, but were not altogether satisfactory. An excellent cupel can, however, be made from a mixture of mabor and bone ash.

PARTING. Perforated sheet-iron trays, each carrying 24 parting cups, and fitting over an electric hot-plate are used.

Failing an electric hot-plate, partings can be done over the hot cupels, covering the latter with a sheet of $\frac{1}{8}$ -in. copper to more evenly distribute the heat. Waste acid, after precipitation of silver, is sent to the smelting house and used in cleansing bullion. The recovered silver is made into silver nitrate.

ANNEALING. The tray of parting-cups is allowed to rest a few seconds on a red-hot cast-iron plate of the same diameter as the hot-plate.

SOLUTION ASSAYS. The procedure is as follows to 20 A.T. of solution add 5 gm. of zinc-dust with vigorous stirring, then enough silver nitrate to ensure parting, and 40 cc. of 20% lead-acetate solution, again with thorough stirring. Finally add 30 cc. hydrochloric acid, cautiously, and stir until all action ceases. Filter and scorify with a flux of 2 parts of litharge, 1 part of borax-glass, and a suitable amount of powdered glass. Nearly all the zinc is eliminated by the acid, and the remainder by scorification.

Scorification is often troublesome in a muffle, where the space is limited, but this does not apply to the hearth of a reverberatory.

This method gives accurate results on all but the most impure solutions.

REDUCED COSTS. Since the use, early in 1919, of a reverberatory furnace, ball-mills, air-pressure filter, etc.,

the total cost of assaying has shown a considerable decrease from the previous year, although more assays were made, the cost of wages and supplies rose, and the cost of new plant was included.

NOTE. POISSON'S LAW. Beringer, in the appendix to his 'Assaying', treats this rather fully. It may be formulated for the present purpose thus: Let x equal the number of gold spheres, y the quartz spheres, and z the combined number of gold and quartz spheres; then $\sqrt{\frac{8xy}{z}}$

equals limit of deviation by error in the number of gold spheres present. To find the mean error the result so obtained has been multiplied by 0.2786.

In the applications given I have calculated the number of spheres of gold and quartz in a 2 A.T. of sample, assaying 20 dwt.

If the present price for silver is maintained to the end of the current year, the total value of Cobalt's production will scarcely reach that of last year, judging from figures available at the present time. On the other hand, should the market price go higher and reach anywhere near the average for the first three or four months of 1920, there is a good chance of last year's figures being passed. With the quotations for silver around 95c., and adding to this the premium on New York funds, the price obtained at present is over \$1 per ounce, and the total revenue for the Cobalt mines is in the vicinity of one million dollars monthly. Last year the silver mines produced \$12,747,621 worth of metal. This sum was obtained from a little over 11,000,000 oz. For the first half of 1920 the indicated output had a value of more than six million dollars, but there is little likelihood of the second half of the year being as productive unless there is an early appreciation in the value of the metal. Conditions at the mines are on the whole satisfactory. Whereas a few months ago many miners were uneasy because of the unsettled state of the market, workers at the present time are more steady and less inclined to cast about for work elsewhere.

The cost of field operations in producing crude oil in California has increased 200% or possibly 300% during the past five years, according to statistics recently published by the State Mining Bureau. In 1915 the operating cost was generally less than 20c. per barrel while in 1919 the figure was in the neighborhood of 40c. or more. Decrease in productiveness of wells coupled with advanced cost of labor and material are the underlying reasons. The total capital invested in the oil industry is about \$320,000,000 upon which dividends of \$35,418,851 were paid, or at a rate of about 11%. About two-thirds of the total output of crude oil is refinable, or above a gravity of 18° Baumé. The total area of proved oil-land is 91,792 acres or 143 square miles. Upon this land there are 8928 producing wells, slightly more than 10 acres per well. Future drilling will probably increase the number of wells until the average amount of land drained by a single well will be 7 or 8 acres.

The Application of the Bradford Flotation Process to Mixed Sulphide Concentrates

By W. D. GREEN and WILLIAM FAGERGREN

HISTORY. From 1916 until April 1919 inclusive the Midvale Minerals Co. was engaged in milling the stored and current tailing from the United States Smelting Co.'s custom concentrator at Midvale, Utah. The process used was flotation, and the product made consisted of a mixed sulphide-concentrate having an approximate composition as follows: zinc 29.2%; lead 10.7%; copper 1.6%; iron 12.5%; insoluble 10.5%; silver 6.42 oz.; gold 0.08 oz. per ton. This product varied, in places containing more zinc or lead, and in places less iron. The concentrate was so low-grade that it was not possible to dispose of it to retort-smelters. However the plant operated during the War and little trouble was experienced in selling the concentrate to an electrolytic zinc refinery. When metals took their drop after the ending of the War the electrolytic refinery cut off shipments. About this time there was being tried a mechanical machine for effecting a separation of the lead from the zinc, and while there were periods when results seemed promising, operation on a paying basis was never reached, so the plant was closed down in April 1919, leaving a stock-pile of some 2000 tons of concentrate that assayed approximately as mentioned above.

DEVELOPMENT OF THE PROCESS. During the active life of the Midvale Minerals Co., one of the present writers had at various times conducted experiments in preferential flotation on the original feed to the mill, employing the several processes developed in Australia, and while results were sometimes successful there never was any consistency in the separation of the lead from the zinc. In fact, while in one experiment it was possible to effect a beautiful separation, on another sample of the same material the results could not be repeated. Results were so unsatisfactory that there was never any attempt to make use of a preferential process on a commercial scale, but every now and then duplication of the Australian work was tried in the laboratory.

About the time that the Midvale Minerals plant closed down the metallurgists for the Stimpson Equipment Co. were having some success in their laboratory in applying the Bradford process to certain ores and at their suggestion the owners of the stored concentrate authorized experimental work to be conducted on the mixed concentrates in an effort to convert them into a salable product. Accordingly work was begun by one of the writers in the Stimpson Equipment Co.'s laboratory in July 1919. The bulk of information available at that time was contained in two magazine articles, one by Edwin T. Henderson, 'The Bradford Process at Broken Hill', *Mining and Scientific Press*, September 28, 1918, and the other by Guy C. Riddell, 'Collective and Preferential Flotation',

'*Chemical and Metallurgical Engineering*', December 15, 1918. As the work progressed, private communications from Mr. Bradford, Mr. Wilton Shellshear, and Mr. Riddell were exceedingly helpful.

Numerous experiments were performed on the concentrates, following more or less closely the method of procedure outlined in the articles mentioned, with very gratifying results. It was not only possible to effect a clean separation, but the two concentrates produced were as good as those resulting from Australian practice. It was found that the iron followed the lead, which was conducive to a high-grade zinc. A large portion of the insoluble, together with much of the lime contained in the gangue, followed the lead, and while it was easy to clean the lead product it was decided to abandon this procedure since as a rule the iron was in excess of the silica and would not be a detriment to its sale-value.

The stock of concentrate, referred to previously, which constituted the feed for the experimental work and also the feed to the commercial plant as finally adopted, not only contained the small amount of necessary flotation-oils but in addition there had been added pine-oil, in varying amounts, to the concentrate as a froth-breaker. Besides this large amount of pine-oil, much lime had also been added to the Oliver filter for the purpose of assisting the filtering qualities of the slimy material. While the lime did not interfere with the Bradford work, the excessive amount of pine-oil caused trouble from the beginning, because as soon as the dried concentrate was mixed with water a voluminous froth was produced. In an effort to counteract the effect of this excessive amount of pine-oil, the feed was subjected first to a preliminary treatment with caustic soda, by adding an amount equal to about three pounds per ton, for three-quarters of an hour, allowing to settle, and decanting the supernatant liquor. Sometimes washing out the remaining soda was resorted to, and at other times not. The pulp thus treated was then made slightly acid with sulphuric acid, saturated with sulphur di-oxide gas, and then treated in the testing machine with sufficient oil to float the lead and iron. Usually when following this procedure the original frothing was eliminated and an entire new froth produced which carried lead-iron and the very finest of the insoluble. A comparatively small amount of oil was required and the froth produced increased in lead content with the duration of the test. The final froth removed consisted of a clean lead product. The whole of the lead-iron and lead were mixed, however, forming one product, which was cleaned afterward by adding a quantity of fresh water and simply introducing it again into the test-machine.

The tailing from the lead treatment was now highly acidified, a small amount of pine-oil added, and the zinc removed. This zinc was cleaned in the same manner as the lead.

The following assays show the contents of the various products resulting from this treatment:

	Lead %	Zinc %	Silver oz.	Copper %	Iron %	Insol. %
Feed	20.2	29.2
Lead-concentrate	41.4	3.5	22.75	3.95	14.1	8.4
Lead-cleaner tailing	24.4	6.4	16.00
Bradford tailing	8.0	4.7	3.40
Zinc-concentrate	2.9	54.9	6.20	1.44	5.3	1.7
Zinc-cleaner tailing	11.4	20.3	8.20

Tests giving these results could be repeated at will. Therefore it was decided to build a small plant of about 25 to 30 tons per 24 hours capacity to ascertain whether or not it was possible to reproduce the laboratory work in a commercial unit. The tests were all run in a Janney test-machine.

MILL-WORK. Because of the ease with which the separation could be effected in the laboratory, the duplication on a large scale appeared to be a simple matter. The necessary tanks for preliminary treatment of the pulp were at hand, and it only remained to build a Bradford machine, arrange the whole into a continuous unit, and proceed. Machines of the Bradford type were constructed for the lead, using open-runner centrifugal pumps as agitators. After every sort of an arrangement for introducing SO_2 gas and air into the machines by way of the pumps was tried they were discarded as a dismal failure.

A sort of a Minerals Separation machine, having connections between the spitzkasten instead of from spitzkasten to the succeeding mixer, had been built to float the zinc from the lead tailing and this was finally used for the lead as well, with satisfaction. Before deciding finally upon this M. S. type of machine, several air and mechanical-air machines were tried without favorable results. It was supposed for a time that introducing air in place of a mixture of air and sulphur di-oxide gas into the pulp would be a detriment to the process, which accounts for the trials with the several types of machines.

The concentrates from the stock-pile were sluiced into a pump-sump and delivered to six tanks 9 ft. diam. by 6 ft. high. This pumping was watched closely in order to obtain a pulp carrying about 25% solid. Whenever the solid fell below 20%, the sediment in the tank was allowed to settle, the clear water drawn off, and the tank re-filled. In this manner the proper density was maintained. As soon as a tank was filled, caustic soda was added in an amount equal to three pounds per ton, the pulp agitated for one hour, then allowed to settle, and the liquor drawn off. The tank was now filled with fresh water and the pulp slightly acidified with sulphuric acid. Then sulphur di-oxide gas was introduced from a sulphur-burner. These steps were all performed with great care in order to duplicate exactly the laboratory practice, but it was found that while the lead and zinc from one tank would separate beautifully, that from another would do nothing. Then we tried washing of the pulp with fresh water after a bath of caustic soda. This gave the

same erratic results. Again the elimination of the caustic soda altogether and slightly acidifying with sulphuric acid was tried. This too gave both good and poor results.

The caustic-soda bath was simply to get rid of the original flotation-oil, but when it was left out the process became exactly a duplication of Australian practice.

In some instances sodium thio-sulphate was added previous to the addition of acid, the idea being to liberate sulphur di-oxide within the pulp by the action of sulphuric acid on the 'hypo'. There did not seem to be any merit in this procedure, although in Australia it is considered essential.

After experimenting for about five months along the lines stated above there seemed to be no hope of transforming the work of the laboratory into practice, and a decision to discontinue the work was practically reached. Up to this point the duplication of Australian work was always in mind and any deviation therefrom to any extent had not been considered. Just at this time a laboratory test had shown that a separation could be made without the use of 'hypo' or acid or a combination of the two, and accordingly the use of sulphur di-oxide alone was tried in the mill. The result was that the work could be duplicated with each succeeding tank of pulp and the prospect of a successful preferential plant suddenly began to re-appear. The plant began to produce a lead-concentrate day after day, and soon three shifts were put on and the plant kept moving. Operations were intermittent owing to the fact that the pulp was prepared in each tank separately. The time required to gassify varied greatly. Occasionally the time required was an hour and a half; at others three hours would be required. The reason for this was attributed to the varying amount of lime that had been added to the concentrate originally.

The tailing from the lead machines was stored in a Dorr thickener and after allowing it to accumulate for a week or so it was treated for zinc by adding acid and heat, and re-floating.

The stock of concentrate began to disappear and it became necessary to replenish the supply. To do this the old Midvale Minerals mill was put in shape to run on U. S. tailing.

PRESENT PRACTICE. There are two tailing-flumes that leave the U. S. mill, each carrying approximately 4500 gal. of pulp per minute, containing $1\frac{1}{2}$ to 2% solid. These flumes are run into a 90-ft. Dorr thickener built of concrete. The sides of the tank are four feet deep. The bottom is conical, and at the apex of the bottom the depth of the tank is ten feet. At the time of its erection this thickener was unique, because the truss is made entirely of concrete and was the longest concrete span in Utah. Besides the current tailing discharged from the U. S. mill, there is also a large tailing-pond. Because the tonnage from the U. S. mill is not sufficient for our operations, tailing from the pond is sluiced into the thickener to make up the necessary tonnage of about 500 tons. The pulp is thickened to 25% solid and pumped with a 4-in. Krogh dredge-pump a distance of 500 ft. to a 36-in. three-section trommel, dressed with 3-mm. punched screen, to remove trash. The undersize from the trommel goes to a 30-ft.

Dorr agitator, which serves as a supply-tank for the selective mill-feed. The discharge from this agitator goes to a bucket-elevator, which discharges directly into two Janney emulsifiers. Flotation-oil is added to the elevator. The emulsifiers discharge to a bank of Janney mechanical-flotation machines. These machines have been remodeled and fitted with air-pans. Air at four pounds pressure is supplied by a Sturtevant blower. There are nine of these machines in series, the tailing from which goes to three Janney mechanical-air machines. The tailing from these goes to waste and the concentrate from all goes to air-cleaners, in which it is cleaned twice. The tailing from the air-machines goes to a thickener, the thickened pulp being discharged to the elevator feeding the Janney emulsifiers. The concentrate from the air-cleaner machines goes to a 30-ft. Dorr thickener, which serves as a feed-supply tank for the lead plant.

Soon after starting operations in the selective mill, it became apparent that a continuous feed to the lead plant would give more satisfactory and uniform results than preparing the pulp intermittently. So four of the lead-pulp tanks were connected in series. The discharge from the 30-ft. Dorr thickener last mentioned is conveyed by an elevator to the first of the lead-tanks, through all of which it flows continuously. Sulphur di-oxide gas is introduced into the first two tanks, proper gassing being regulated by returning varying proportions of the feed going to the lead-machines back to the first tank. The pulp is maintained at 20% solid and flows from the fourth tank to a 3-in. Krogh sand-and-tailing pump, to be delivered to the feed-box of the lead-machines.

The lead-machines consist of four 6-ft. Fagergren flotation machines in series. These machines were invented some three years ago and have been perfected to a high degree of efficiency at this plant. The outstanding features are that they maintain their efficiency throughout the life of parts, while in any other type of machine the efficiency begins to decrease the moment that they are started; the pulp is always in motion and the froth is still except for its movement upward and over the lip; it is practically fool-proof, because there are no adjustments once the pulp-level has been established.

Oil is added to each of the machines; the amount, of course, being regulated as required. The lead-concentrate carries an excessive amount of fine silica, which makes the subsequent filtering very difficult. This concentrate is sent to a 30-ft. Dorr thickener, and the thickened concentrate to a 6 by 6-ft. Oliver filter. Live steam is introduced directly into the pulp within the filter, thereby hastening the filtering operation.

The tailing from the lead-machines goes to a 30-ft. Dorr thickener from which it is drawn and pumped to two 8 by 10-ft. tanks. The time element is an important factor in the treatment of the zinc. The SO_2 gas must be eliminated; this is accomplished by the addition of sulphuric acid and heating to 130°F. The time required for the action of the acid and heat varies so that up to this writing it has not been possible to run the zinc plant continuously. By this is meant having a continuous flow from the Dorr to the machines; the pulp being prepared

in the tanks separately and treated as soon as they are ready, which is determined by trial. This makes the operation of the zinc section sluggish although satisfactory.

From these 8 by 10-ft. pulp-tanks the feed flows to two 6-ft. Fagergren flotation-machines, where a very small amount of oil is added and the zinc floated off. These machines were a great surprise because practically all the zinc is removed on the first machine; what little does come off from the second machine is returned to the air-machines of the selective plant. The first machine makes a concentrate running as low as 2.5% insoluble, the average being 3.8%. The tailing runs as low as 1.5% in zinc and 1% in sulphide lead. This zinc operation amounts to the same thing as a cleaning operation in other mills, and as far as we know from experience, or are able to learn, there are no other cleaners in the country doing like work on a whole series, let alone on one machine. The tailing is kept so poor that it is thrown away. The concentrate is dry enough to be sent directly to an 8 by 8-ft. Oliver filter.

Since the operations have included the treatment of U. S. tailing, the iron has shown a decided inclination to remain with the zinc, so that it has become impossible to make better than a 42%-zinc concentrate. It had been noticed, however, that on warming the solution in preparation for the zinc-machines an iron froth formed on the tank. Consequently, test-runs were made taking this heated pulp and re-running it before adding acid and sending it to the zinc-machines. These tests have shown that it is practicable to remove an iron-lead product which leaves a tailing from which it is possible to make a 50%-zinc concentrate. Accordingly, the mill is being arranged to do this.

The following assays are taken from daily operations:

		Selective Plant								Air-concentrate			
		Mill-feed		Janney-feed		Mill-tailing		Lead		Zinc		Lead	
		Zinc	Lead	Zinc	Lead	Zinc	Lead	Zinc	Lead	Zinc	Lead	Zinc	Lead

Eighty per cent of the lead in the zinc-tailing consists of oxidized lead, the other 20% being lead sulphide.

Blast-Furnaces at Copper Cliff

The following description of the blast-furnaces used at the Copper Cliff plant of the International Nickel Co. appeared in the August Bulletin of the C. I. of M. & M. There are eight furnaces in this department. Five of them are 17 ft. long, one is 21½ ft. and two are 25½ ft., giving a total furnace length of 157½ ft. All have the same width at the tuyeres, namely, 50 in., and are similar in construction throughout except for such differences as are due to the different lengths. The cast-iron hearth-plates are supported by 12-in. I-beams laid transversely to the furnace length. No cooling is provided for these plates beyond that due to the air naturally circulating under them. The crucible of the furnace is built of chrome-bricks, which, at the sides, come up to within 6 in. of the tuyeres and are stepped down to the centre in the form of a 'V', the minimum thickness of brick being 18 in. The sides of the furnace are formed of sections 4 ft. 3 in. wide, containing six jackets for the full height of the furnace. First there is a pair of cast-iron tuyere-jackets (in which are embedded 1½-in. water-pipes), each 2 ft. 1½ in. wide and 4 ft. 7 in. high, resting on the hearth plates. Each of the pair has, near the top, two tuyere-openings 6 in. diam. Above the tuyere-jackets is another pair of cast-iron jackets of the same width and of similar construction, but only 3 ft. 11 in. high. Above these is a steel water-jacket 3 ft. 6 in. high and 4 ft. 3 in. wide, and finally another steel jacket 6 ft. high and 4 ft. 3 in. wide.

The use of the small steel jacket was made necessary when the height of the furnace was increased several years ago. The cast-iron jackets are given a slope outward to form the bosh of the furnace, the maximum inside width being 5 ft. 10 in., an increase from 2 ft. 10 in. at the hearth-plates. The steel jackets are vertical. The 17-ft. furnace requires four of these sections to the side, the 21½-ft. furnace, five, and the 25½-ft. furnace, six. At the dead end of the furnace the lowest jacket is of cast-iron with water-pipes imbedded in the same way as with the cast-iron side-jackets. It is 3 ft. 9 in. high and above it are three steel water-jackets, 4 ft. 9 in., 3 ft. 6 in., and 6 ft. high, respectively. At the front end the lowest jacket is of copper 32 in. wide and 5 ft. long, with the

lower edge 1 ft. 11 in. above the hearth-plates. This forms the trap of the furnace. The top of the copper jacket is the same height above the hearth-plate as the top of the cast-iron jacket at the dead end, and hence the remainder of the jackets at the front are the same as those at the dead end. Each furnace is provided with a small side tap-jacket fitted into a notched tuyere-jacket and placed near the middle of the furnace.

The spout is of chrome-brick built against the copper jacket. It is carried on a 4-in. cast-iron plate about 4 ft. wide and 5 ft. long, which rests on the bottom plate of the furnace and the side of the settler. Cast-iron water-cooled side-plates retain and protect the brick. A water-cooled cast-iron lip is placed where the mixed matte and slag flow from the spout. Further protection to the brick is given by another cast-iron cooler placed under the lip. The effective depth of the trap formed by the spout and the copper jacket is about 9 in. This type of spout was developed at the plant to overcome trouble with corrosive low-grade copper-nickel mattes, and has proved very satisfactory. A cut-out of the spout is practically unknown.

At the Creighton mine of the International Nickel Co. the same rounds are drilled in all drifts and cross-cut headings, varying only in the number of 'easers'. The four-hole centre-pyramid cut is used, and from 17 to 22 holes, usually 19, are drilled in a round. Great care is taken to bring the cut-holes near to the point of intersection, and to properly place the 'easers'. Cuts are blasted and enlarged separately, before the 'square-up' is blasted. Rounds varying in length from 6½ to 7½ ft. are broken. Polar Forcite of 40% strength is used for all classes of work. Experiments with different types and lengths of rounds have been conducted. Rounds averaging 10 ft. in length were broken during a period of 30 days with the same speed per machine-shift and less powder per foot driven, but the large amount of broken rock to be handled interfered with the cycle of operations. Two Sullivan (DR6) drills are used in each heading. The air-pressure is 100 lb. Hollow hexagonal steel 1½ in. diameter is used. Cross-bits, with 14° and 5° taper and reaming edge, are gauged 2½ in. on 2-ft. 'starters' and decrease ⅓ in. per foot to a length of 8 ft.; thereafter the decrease is ⅓ in. per foot to 14 ft., and there is a difference of ⅓ in. between the gauge of 14-ft. steel and that of 20-ft. As it is necessary to drill 16-ft. holes in the stopes, and as the bits of 16-ft. steel are 1⅝ in. diam., this bit-gauge is used throughout the mine in order to avoid confusion and to standardize shop-work. Experiments are being made with small-gauge bits on development work, commencing with 2-in. 'starter' bits and finishing with 1½-in. bit at 10 ft. A 7½-ft. round in granite is drilled in one and one half shifts, or three drill-shifts. During the period from July to December 1919 the advance per drill-shift in drifts and cross-cuts was 2.3 ft., consumption of powder averaging 19.4 lb. per foot driven. Drills are tested on a granite block in the repair shop and must cut three inches per minute using a 2½-in. bit.

Some Cornish Mining Terms

By T. A. RICKARD

The origin of many terms now an integral part of the miner's vocabulary is to be found in the glossary annexed to a fine old book called 'Mineralogia Cornubiensis', by William Pryce, 'of Redruth in Cornwall'. This volume, published in 1778, is a Cornish 'De Re Metallica' and contains much of the same kind of shrewd commonsense as distinguishes the more famous book by Georgius Agricola, now known to the profession by means of Herbert Hoover's translation. Indeed, Dr. Pryce quotes his predecessor of 1556 more than once.

The learned Cornishman calls his glossary 'An Explanation of the Cornu-Technical Terms and Idioms of Tinnars'. It is interesting because it gives us the origin of many familiar words. For instance, 'winze'. This is a corrupt form of 'winds', namely, a place where they wind. The word 'wind' is Old English and means to go in a curved or circular course, as around a windlass, in which *windill* = winder and *ass* = beam. In the North of England, says Pryce, a 'winds' is called 'the turn', referring to the axletree or cylinder on which as it turns the rope is wound. 'Little-winds' is defined as "an underground shaft, sunk from a horizontal drift, by which the top of the winds communicates with the side or bottom of the grass working-shaft". 'Grass', we are told, "signifies on the surface of the earth". For example, "Is Tom Treviscas underground? No; he is at grass". "He is on top", as we would say.

'Costean' is Cornish; it comes from *cothas*, to find, and *stea*, tin. Pryce also gives 'dropt-tin' as the equivalent, suggesting that 'to find' is not the literal translation of *cothas*. To costean is to dig a pit to bedrock in search of ore.

'Gad' is Cornish for wedge. 'Cob' is "to break or bruise". 'Spal' is "to break large solid blocks of ore with sledges to a smaller size, in order to cull out the barren stony parts". A 'gossan' is "a kind of imperfect iron ore, commonly of a tender rotten substance, and red or rusty iron color. It is an upper covering to the ore". The German *eiserner hut*, or iron cap, is expressive. 'Jigging' is "a method of dressing the smaller copper and lead ores by a peculiar motion of a wire sieve in a kieve or vat of water, where the smallest particles pass through the jigging-sieve, and those which are larger and solid lie at the bottom of the jigging-sieve or jigger; so that the uppermost light stony waste may be easily separated and skimmed off by a piece of semicircular board, called a limp". 'Plat', as we use it, is a corrupt form of 'plot'. Pryce says: "to cut a Plot is to make room, or square out a piece of ground by the side of the Lode or Shaft, for holding broken work or deads before they are brought to grass or for other convenient purposes". Dr. Pryce's definition of 'horse' is not a happy one; he says: "A portion of dead ground in a Lode, which widens like a horse's back from the spine". Surely it comes from the fact that when the lode is split by a wedge of rock, the lode rides it with a leg on each side. I am re-

minded of the story told of Clarence King, who was sent to examine a mine in Utah in which a 'horse' was reported to have spoiled the prospects of continued productivity. He found more than one horse, so he telegraphed to the directors: "Your mine is a regular livery-stable". 'Resue' has almost gone out of use, but the Cornish in Gilpin county, Colorado, and those at Grass Valley, California, will be found to retain it. It means the stripping of veins in a stope, by removing the adjacent rock first and then taking down the ore separately, and cleanly. Pryce gives it as 'dizzue', and says: "To dizzue the Lode is this: If it is very small and rich, they commonly only break down the country or stratum on one side of it, by which the Lode is laid bare, and may be afterwards taken down clean and free from waste . . . The refuse or deads of a Dyzhued Lode is called in some places the Dyzha". Note how he says "dyzhued", not 'dizzued', because 'dizzue' comes, he says, "from the Cornish 'dyzhue', to discover unto". In Cornwall they still use the form 'desue'. It is possible that 'resue', as suggested by Mr. R. Arthur Thomas, comes to us not from the Cornish but from the Welsh, for the Welsh word 'resgyw' means to liberate, to open, to make loose, or set at large.

Another interesting old word is 'vug', sometimes written 'vugh' in order to indicate the hard sound of the 'g'. Pryce says: "'Vooga'. Smoak. We also call a hollow cavern, either in the earth, or the Mines, or by the fretting of the sea, a Vooga; in the Mines, a Vooga-hole." So today the American miner speaks of a vug or vug-hole, meaning any small cavity in the lode. It is commonly a place for finding crystalline growths and beautiful specimens of minerals, which, owing to the space becoming filled with clay or slime, have had an opportunity to develop without interference. 'Vug' used to mean smoke or a place for smoke. The Welsh have 'fwg', smoke. The 'w' in Welsh sounds like 'oo' in food, says Mr. Thomas. Again we have the likeness between Cornish and Welsh, both of which languages are descended from the Armoric branch of Celtic. Welsh is a living language today, whereas the last person to speak Cornish died about forty years ago.

Many of the Cornish terms came from the miners of Saxony, who preceded the Cornish themselves as the professors of mining. Freiberg was a school of mining before Redruth, and Dr. Pryce acknowledges the fact, etymologically, in his glossary. To the Saxons we owe 'stope', a step; 'stull', from *stolle*, a prop; 'shaft', a groove or pit. 'Sump' or 'sumph', says Dr. Pryce, is "a pit sunk in the very bottom of the mine; it serves as a basin or reservoir, to collect the water of a Mine together, that it may be drawn out by an engine or machine".

'Shode' is an old Cornish term of Teutonic origin. Probably from *shutten*, to pour forth. "Shoding", says Pryce, "is the method of finding veins of Tin by digging small pits in order to trade out the Lodes of Tin, by the scattering loose stones and fragments that were dispersed from them by the retiring waters of the deluge: these loose stones thus dispersed are Shode stones". This the American miner calls 'float', which also suggests a "deluge", in other words, the sorting action of rainfall

and rivulet. Dr. Pryce spells 'deluge' with a small 'd', but he appears to be referring to the Noachian fable. Another curious Cornish word is 'learies', which means emptiness and refers to old stopes. Undoubtedly it is a form of 'leeries' and comes from the German *leer*, meaning 'empty'. From the French, probably through Brittany, from which so many of the Cornish migrated, we obtained 'van' and 'vanning' shovel. Dr. Pryce says: "Van (From the French, Avant, foremost). To make a Van is to take a handful of the Ore or Tin-stuff, and bruise, wash, and cleanse it on a shovel, to shake and throw forth upon the point of it almost all the Ore that is freed from waste." . . . "Quarrie. When a Lode or Stratum breaks in large hard rocks, being jointed, as it were, it is called a Quârey Lode or Stratum, for its joints or Quâres." The word comes from the Latin *quadrare*, to square. Note how under the definition of 'Plot' or 'Plat', Pryce says "to square out a piece of ground", meaning to excavate a space square in plan. The French word for 'quarry' is *carrière*, from *carré*, square or quadratic. 'Huel' is another word that links Brittany with Cornwall. It survives in both, although in the English county it is often spelled 'wheal'. Pryce says: "Huel. A Work, a Mine; as Huel Stean, a Tin Mine: Huel Kalish, the hard work." Notwithstanding this, the Cornish will say Huel Virgin Mine, which means 'mine Virgin mine', showing how the original significance of 'huel' is ignored. There was a mine called the Great Wheal Work, a name in which 'wheal' and 'work' are synonyms. Pryce gives, "Core (i. e., Corps; body, company, society). Corps is used among the military, and pronounced Core. With the Tinnars it has also a respect of time, such as their proper change or turn of working. Thus it is said, the first Core by night is eight o'clock, for instance; the second Core is four after midnight, and the day Core commences perhaps at noon-day, according as the labourers will settle among themselves. But in difficult and hard working places, where water is too troublesome, or air is very deficient, they divide their Cores into four; that is, every six hours." Thus 'core' is equivalent to 'shift'.

Let us conclude with some familiar Cornish words; for example, 'elvan'. Pryce says that it means "a very hard close-grained stone, thought to be bastard limestone". It comes from 'elven', in Cornish an element, a spark of fire". Evidently a stone against which steel strikes fire. Since Pryce's time it has become synonymous with igneous rock, especially granite, in dike form.

'Flookan', says Pryce, is "an earth or clay of a slimy glutinous condition". Again, "a small slide is also a fissure filled with clay or Flookan". The form 'fucan' is usual nowadays.

Last, there is our old friend 'quartz'. Pryce spells it 'quarts'. He says: "A hard, opaque, and sometimes semi-transparent crystalline stony mass, vulgarly called Spar, which it is not, being a chrySTALLINE basis". The 'h' in 'chrySTALLINE' shows that typographic errors were made a hundred years ago, as today. Pryce says nothing about its derivation, which is from the German *quarz*, without the 't'. The use of 'quarts' explains why some

old Cornish miners speak of "them quarts". Many years ago, at Melbourne, E. J. Dunn, the distinguished geologist, told me how when he was a small boy among a ship-load of emigrants on their way to the gold diggings of Ballarat and Bendigo, he heard the word 'quarts' used by the unsophisticated as if it meant double pints. They expected to find gold in quarts!

THE Mule Creek oil-field is in eastern Wyoming, only 4 miles from the South Dakota line, about 35 miles north-east of the well-known Lance Creek field and 100 miles east of the Salt Creek field. It is the most productive field in Wyoming. The presence of petroleum in commercial quantities in this region had long been suspected, and in recent years considerable drilling had been done on a prominent anticline there, but most of it was done to validate claims, and, though many 'shows' of oil were reported, the wells were not sunk deep enough to test the anticline thoroughly. In 1919 the geologists of the Ohio Oil Co. discovered a second anticline south-east of the prominent anticline to which drilling had been confined, and the company drilled on this south-eastern anticline a test well which proved to be the discovery well of the field. The production of this first well was small compared with that of the wells in the near-by Lance Creek field, but its success stimulated extensive drilling, and by the fall of 1919 about 10 wells on the south-eastern anticline were each producing daily 125 to 150 barrels of oil of high grade. Drilling was not confined to the south-eastern anticline, however, and late in 1919 no large quantity of oil had been found except in wells drilled near its axis. The Mule Creek oil-field is described in a report by E. T. Hancock just published by the U. S. Geological Survey as Bulletin 716-C, which may be obtained free of charge.

COPPER-NICKEL ore is roasted in beds at Copper Cliff, Ontario. The only preparation required before beginning to build a bed is to lay the wood necessary to start the roasting. The wood for each bed covers a rectangular area about 100 ft. long and 60 ft. wide. The width is determined by the distance between the railroad tracks, but the length is largely a matter of convenience in building and lighting. The fuel used is the usual 4-ft. cordwood, and it should be of good quality. The finished bed contains about 5000 tons of ore. The beds are lighted as soon as possible after the building is completed. As the wood burns away, the ore settles down and cracks develop in the surface of the bed. This is the critical time of the process, and bed-trimmers are constantly on the alert, during the first week or two of the burning, to close these cracks as quickly as possible. After the subsidence is completed no more openings are likely to form, and the bed requires practically no further attention. It will probably burn for six or seven months, by which time the sulphur will be reduced to about 10%. The roasted ore is re-claimed from the beds by two Atlantic steam-shovels having a dipper capacity of 2½ cu. yd. They load the roasted ore into the same 50-ton cars that bring the green ore from the mine.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

RESULTS AT THE SUPERIOR & BOSTON.

GLOBE.—A strike was called at the Arizona Commercial Mining Co.'s mine, the reason given being the discharge of one of the shift-bosses, who was very popular with the men. At the Miami Copper Co.'s plant the portal of the lumber-yard tunnel is being concreted. The completion of this tunnel will greatly facilitate the handling of all timber as it will then be possible to take the timber from the yards direct, on the same level, to the No. 5 shaft, through which it will be lowered to the various working levels. The timber is at present being hoisted up a long incline to the collar of No. 4 shaft and then lowered to its destination. Rapid progress is being made in the underground connections between No. 5 and No. 4 shafts, connections having been completed on the 570-ft. and 720-ft. levels. The 850-ft. drift from No. 5 has been driven to a point below the bottom of No. 4 shaft and raising from this point to make connection with shaft No. 4 will be started at once. It is reported that the Atlantis Mining Co. at Payson is making good progress in developing its silver and gold property. A force of men is now engaged in sinking a shaft on the Atlantis claims. The diamond-drilling at the Ray Boston Copper Co.'s property near Kelvin is said to have reached a depth of 1440 ft. and is expected to cut the vein within the next 40 or 50 ft. Future development will, of course, depend largely on the core-showings at this depth. In his recent report for the third quarter of the fiscal year, 1919-'20, T. R. Drummond, president of the Superior & Boston Copper Co., states that during this period 2156 ft. of development work was done, in addition to 2007 ft. of diamond-drilling, as compared with 2211 ft. the previous quarter, and 1301 ft. for the same quarter last year. From this development work 9065 tons of waste has been hoisted, in addition to 2254 dry tons of ore from development work and stoping. This ore has averaged 5.56% copper and 13.35 oz. silver. The net smelter-returns were \$44,455.65, an average of \$19.73 per ton. This includes several cars of low-grade silicious ore, which have been shipped to local smelters and on which a favorable rate was made as this class of ore is in demand. The replacement of decayed timbers in the McGraw shaft has been completed. The collar set has been concreted and the shaft is now in good condition. Fuel-oil consumption in the power-plant has continued to decrease, June consumption being the lowest of any month in recent years. Against this the price of fuel-oil is 17% greater than last year, so that the saving by the decreased consumption amounts to only \$250 per month compared with the cost in June of

last year. The amount of water to be pumped continues to decrease. In June less than seven million gallons was pumped as compared with over eleven million gallons last June. On July 1 the company had a balance of cash and cash assets of \$145,727, not including ore in transit.

TUCSON.—The annual convention of the Liga Protectora Latina, an association of the Spanish-speaking population of the south-west, formed especially to combat radical propaganda, and composed almost entirely of American citizens, was held recently at Tucson. The order has a membership of approximately 2500 members.

Mining conditions in general were discussed at length at the quarterly meeting of the Arizona chapter of the American Mining Congress, held at Tucson on September 13.

WARREN DISTRICT.—Recent strikes of copper ore in the White Tail Deer section, the southern end of the Warren district, are of great importance and indicate the future extension of mining operations into this part of the district. A big body of sulphide ore of good commercial grade was recently opened up by the Boras Leasing Co. on the 600-ft. level of the property belonging to the Copper Queen Mining Co. Oxide and carbonate ores had been mined on a small scale in the White Tail Deer section for the last few years, but this is the first discovery of sulphide ore that has been made there. The orebody has not been fully developed. The Calumet & Arizona Mining Co. has completed a ventilation-shaft, sunk for the purpose of providing an outlet for smoke and fume from a fire-area in the Briggs mine between the 1300 and 1400-ft. levels. The total depth of the shaft is 786 ft. and it is connected by drifts with the fire-area, which is bulkheaded off from the rest of the mine, the only outlet being through this shaft. It is thought that there is no actual fire in the mine at the present time, but the admission of air into the sulphide stopes probably would fan the flames into action again.

GLOBE-MIAMI DISTRICT.—Taking the output for the eight months of the current year as a basis, the Miami Copper Co. will produce the largest amount of copper ever recorded by the company, with the possible exception of 1918, when, under the stimulus of a heavy war demand, the output for the year totaled 58,500,000 lb. More than 37,000,000 lb. has been reported up to the end of August, indicating approximately 56,000,000 lb. for the full year. This showing comes in the face of a stagnant copper market and is possible on account of low producing costs at Miami.

BISBEE.—The North Tigre Leasing Co.'s mill, recently

started up, is reported as running satisfactorily. Three carloads of concentrate have been shipped to the smelter at El Paso. The output has been curtailed owing to the shortage of water, but it is expected that this difficulty will be overcome within thirty days. It is reported that a large body of 12% azurite copper ore has been opened in the Night Hawk mine. The ore was cut in the 650-ft. level, 250 ft. east of the shaft. One hundred feet of the ore has been exposed by drifting and it is expected that the orebody will extend to the Boras side-line and connect with the sulphide ore recently opened on that property. A raise which is being made from the Boras drift has advanced 15 ft. and is still in ore. This work proves the ore over the Boras drift, although when the drift was first run the ore was not found. James McKenna is superintendent. The recent strike of sulphide ore in the Boras lease has stimulated interest in the Don Luis region and the Don Luis Development Co. has been formed to take over the Finerty property, the litigation of which has been adjusted.

CAMP VERDE.—W. P. Blake has briefly described the deposits of glauberite, and associated minerals, a mile and a half south-west of this place, in a report to the Governor of Arizona. The deposits are 60 ft. thick in places and cover a considerable area. The Western Chemical Co., of Tonopah, W. B. Roberts, president, has recently leased two sections of this area, one from the State of Arizona and the other from private interests. It is the intention of the Western Chemical Co. to mine and ship for the present 100 tons of the natural salts to the refinery at Los Angeles, California. It is said that the resulting sodium sulphate is to be shipped to paper-pulp manufacturers in Finland.

JEROME.—Rock to the extent of 50,000 cu. yd. was recently blasted by ten tons of dynamite in the present steam-shovel operations of the United Verde. The blasting was carried out by means of four 110-ft. churn-drill holes. The holes were sprung by 600 lb. of powder each.

OATMAN.—It is announced by the directors of the Tom Reed Mining Co. that the dividend rate is to be reduced to one cent per share per month, payable quarterly. This reduction is deemed necessary to provide funds for the large amount of development and prospecting that is now being done and at the same time build up a substantial reserve. The gross production of the United Eastern Mining Co. for the first seven months of 1920 was \$1,213,657 and dividends paid out by the company in the same period were \$776,910. The gross production of the Tom Reed for the same period was \$452,628 and during that time it paid about \$111,000 in dividends. It is reported that the United Eastern Mining Co. has installed a diamond-drill to carry out extensive exploration at depth.

TOMBSTONE.—The Solstice Mining & Milling Co., owned by Boyd, Hughart, and Bludworth, has made the final payment for the purchase of the property. Engineers have reported that silver ore to the value of \$120,000 is at present available in the mine. It is the plan of the company to install a 50-ton mill, hoist, air-compressor, and cyanide tanks.

COLORADO

NEW FIND IN THE VARNEY TUNNEL.

ASPEN.—Large bodies of silver-lead-zinc ore have recently been encountered in the Varney tunnel in the Woody Creek-Porphry Mountain district north of this city. The ore is claimed to be 30 ft. wide, part running 50% zinc and the remainder 20 oz. silver, 40% lead, and 30% zinc. The principal owners are D. M. Hyman and New York associates. The same interests are planning another tunnel into the mountain facing Porphyry where surface showings are reported better than at the Varney. The Aspen Silver Lead Mines Co. has cut the main ore contact on Porphyry mountain in its tunnel now 800 ft. long. The property lies just north of the Varney, and it is expected to cut the silver-lead ore-shoot in the next 100 ft. The Anaconda group north of the Aspen Silver Lead group has also cut the contact and has an excellent ore showing. This group is owned by Aspen miners who have spent considerable money and many years in its development. Rich ore has been uncovered in the Mayflower claim by the Park Tunnel company, operated by Leadville and local men.

The Smuggler management is adding more powerful pumps to unwater the mine and extract the lead-zinc ore standing in the old fire-stopes. The Hope company owning the Little Annie group 9 miles south of Aspen is installing electric power. The Hope tunnel has reached the Weber limestone-porphry contact and it is expected the main ore-shoot will be cut soon.

CENTRAL CITY.—The Evergreen shaft has been sunk to the 850-ft. level, a station cut, and drifting started. It is reported that a Denver syndicate, operating the Annie B., is mining high-grade gold-silver-copper ore. The Barrick tunnel of the Saco de Oro company has been driven 850 ft. and the heading is reported to be highly mineralized with tale streaks containing fair amounts of gold. The objective point under the Rochester shaft is still 170 ft. distant, but it is expected that the vein which produced rich silver-gold ore in the shaft at 250 ft. will be cut on its dip within the next 100 ft. The tunnel will be 400 ft. beneath the shaft.

MICHIGAN

SHIPMENTS INCREASING

CALUMET.—Small lots of copper are being shipped from the smelters to fill domestic orders. August refined-copper shipments from all the mines totaled 16,860,000 lb., an increase of over 6,000,000 lb. compared with July. August shipments greatly exceed those for any month of this year. The figures include only lake shipments, a small amount having been shipped by rail. Considering the comparatively dull market, the August record is refreshing, for it is 5,000,000 lb. in excess of the combined production of all mines.

The tonnage derived from the removal of pillars and the cleaning up of arches and backs of old stopes at the C. & H. will be less than in 1919 when 63 drills were employed exclusively in this work. In 1918, a battery of 80

drills was in commission in the final clean-up and a half million tons of 'rock' was recovered, compared with less than 350,000 tons last year. The old workings yield an immense amount of 'rock', particularly as the operations approach the surface, for there the strips of conglomerate run better than 80 lb. per ton. The removal of shaft-pillars in the Hecla department alone will be an undertaking that will take years to complete, because solid columns, nearly 100 ft. thick, extend from the surface to the bottom. All these pillars will be removed eventually and the shafts sealed, but not until operations extend below the 80th level, after which hoisting will be done through the haulage-way now nearing completion.

Arcadian Consolidated should reach the 600-ft. level in the New Baltic shaft within a few days. After cutting the 'plat' a cross-cut will be made into the vein and

Cross-cutting on the Ahmeek fissure at the 16th level of No. 2 shaft has reached a point 300 ft. from the Kearsarge Conglomerate vein. On the 11th and 18th levels the tunnel is being driven toward the same formation. The fissure on the 16th level has reached a width of three or four feet and, as has been the case since it was first opened west of the shaft, it is rich in 'mass' copper. Drifting in the 'mass' fissure has been under way eastward from the 15th to the 22nd levels, except the 18th, while openings from the 22nd to the 26th, including the stopes, have developed ground that is entirely satisfactory. No. 2 shaft continues to show the richest ground and occasionally boosts the yield to more than 26 lb. per ton. By the end of the year it is expected that No. 4 shaft will have attained a depth of 175 ft. below the 21st level, nearly 3000 ft. On the hanging-wall side of this

NO. 2 SHAFT OF THE ARIZONA COMMERCIAL, COPPER HILL, ARIZONA

drifting started north and south. As only 10 or 15 ft. of cross-cutting is necessary before the lode is tapped, it should be a matter of not more than fifteen days before drifting is under way. Considerable interest is centred in Arcadian developments, for the disclosures of each succeeding level are important, not alone to the Arcadian but to properties on the north. The fourth level revealed a splendid showing and on the fifth level even higher-grade ore was reported. Accordingly there is a prospect that heavier mineralization will be noted on the sixth and downward. If this proves to be the case, the old fallacy about the ore becoming leaner with depth will be exploded. The only mine that opens leaner ground as it becomes deeper is the Calumet Conglomerate, for even Quincy, which has paid dividends since 1862, still yields nearly 22 lb. per ton. The ore developed by practically all of the Kearsarge-lode shafts is as high-grade as when the vein was first tapped and the Pewabic vein on Franklin property shows far better ore on the 39th level than 1000 ft. nearer surface. The Copper Range mines likewise are producing better ground than ever. While metallurgical developments account for some of the greater recovery, increase in the metal content of the ore is the rule as each shaft is deepened.

shaft, two feet of ore has been opened. There is no material change in No. 3 shaft so far as the grade of 'rock' is concerned. The most gratifying feature of Ahmeek's operations is the fact that the ore in No. 4 shaft, the most northerly, continues to improve in value with depth, while to the south Ahmeek has territory that has great possibilities. The fissure, however, is attracting the greatest attention at present, for it will provide an opportunity to do extensive exploratory work on the Kearsarge conglomerate at a place distant from the original openings.

White Pine, with a force of about 70 men, is producing a negligible quantity of refined copper, compared with its peak-production, although operations are going forward in preparation for the future. There is little probability that the force will be further reduced. With the present number of men it will be possible to develop ground that will yield a profit when market conditions become normal. With this mine situated so far from more thickly populated centres, the retention of the nucleus of a working organization is desirable and necessary to ensure an efficient crew later.

Power-lines are being erected between the Calumet & Hecla mills and Ahmeek, connecting with intervening

subsidiary mines which will be supplied with electricity and power by the parent company. Although it will be a long time before the new turbines at the mill are in commission the present supply may be sufficient to operate the new electric pumps at Kearsarge. For some time No. 1 Kearsarge shaft has been hoisting nothing but water, and bailers are in constant operation to handle water that seeps through from the surface as well as the flow from the abandoned South Kearsarge shafts.

Practically all the equipment of the old Tamarack mill has been moved to Calumet, where parts of it will be prepared for future use and the remainder scrapped. Excavating for the flotation and leaching units of the reclamation plant has begun. A large part of the steel to be used in the buildings, or at least the super-structure, will come from the old coal-storage structures at Hubbell, which were dismantled a year or two ago. The hoist at North Tamarack No. 3 shaft has been moved to Isle Royale, where it will go into commission at No. 5 shaft.

Seneca's fifth level 'plat' will be cut within ten days and before October 1 drifting will begin. In the meantime there will be no let-up in the work in the third and fourth levels, north, and by the time the fifth is well under way the shaft will be sunk to the sixth level. At Gratiot, the 13th-level south drift is progressing, with operations under way by two shifts. There is no change in the condition or quality of the ground.

Mayflower-Old Colony is continuing the raise in the west cross-cut, instead of abandoning this exploration as originally planned. The south cross-cut has entered trap after having been in 'rock' for 180 ft., but it will be continued in the hope that copper-bearing ground will be found again.

NEVADA

DESCRIPTION OF THE DAYTON DREDGE.

DAYTON.—The new all-steel dredge, completed September 5, is now being operated steadily. It weighs 900 tons and has a nominal capacity of 7000 cu. yd. per day, although it is expected that uneven ground and boulders will limit its effective capacity to 5000 cu. yd. per day. While the dredge does not approach in size or capacity some of those operating in California, it is said to be the perfection of dredge design. It is the first in Nevada made of steel construction, and the first anywhere in which all the deck-plates are electrically welded. It has 9-ft. draft and was built in four months working time at a cost of \$350,000. Some of the structural material was taken from two old dredges of the company near Marysville. The dredge floats in an artificial pond on a bench 30 ft. above the bed of Gold creek and within a few yards of the spot where gold was first discovered in Nevada. Placer-gold was found here by Mormons early in 1850 and the creek-bed was worked in a primitive way, part of the time by Chinamen, until 1859, when the placer miners working farther up the canyon discovered the Comstock lode. Placer mining was then discontinued, but in later years some small-scale hydraulic mining was done. The company has secured, under deed or lease, 700 acres, and

has tested them by drilling and sinking shafts over 200 acres. It is said that the tests show an average gold content of 31½c. per cu. yd., and earlier tests and reports show 50 to 60c. Hydraulic washing of 24,000 cu. yd., several years ago, yielded 58c. per yard. The gold is coarse and many good nuggets have been found. Bed-rock is from 14 to 40 ft. deep. Power is secured from the Truckee River hydro-electric plants supplying this region, and water from the Marlett Lake flume supplying Virginia City. The water is taken from the reservoir at the south of Mount Davidson and runs down American canyon to Gold canyon, whence it is carried in a 6-in. redwood pipe to the dredge.

ELY.—The first secondary-enrichment contact-deposit of sulphides of economic value developed in the Nevada Consolidated has been opened for a length of 60 ft. on the 700-ft. level of the Ruth mine, according to C. B. Lakenan, general manager. The ore contains 7% copper and it is reported that since the official statement was made the drift has been extended to 100 ft. and a cross-cut has been started to determine the width of the ore-body. This is the extension of the orebody on the 500 and 600-ft. levels, where the average copper content was 2½%.

PIOCHE.—Shipments have been made from the district recently at a rate of 11,000 to 14,000 tons monthly. During the past two weeks the Prince has shipped 3850 tons; Virginia Louise, 1150; Bristol, 350; Con. Nevada-Utah, 200; Black Metal, 200; Combined Metals, 200; Ida May, 40. Drifts have been driven to a total of 50 ft. from the bottom of the 75-ft. shaft sunk by lessees on the Burke mine of the Amalgamated Pioche. Ore was found in the shaft at 65 ft. and the drifts are being driven in ore. There is a rich seam 8 to 10 in. wide in both drifts that assays 0.18 oz. gold, 72.5 oz. silver, and 52.6% lead. The lessees have mined 25 tons of ore for shipment. The shaft will be sunk deeper and the drifts continued. The Bristol is making a production that last month reached 1000 tons from the Lloyd-Bent winze, at a depth of 800 ft. The contact of the ore, according to analyses made in Salt Lake smelters, is 0.02 oz. gold, 23.2 oz. silver, 12.5% lead, 3.3% copper, 6.7% zinc, 10.5% iron, 1.7% manganese, 1% sulphur, 23.5% insoluble.

STONEWALL.—Because the Sterlag tunnel of the Yellow Tiger cost \$30 per foot to drive, the company has stopped work until the cost can be reduced. Gordon M. Bettles, manager, says the cost can be reduced one-half by using a heavier drill, storing oil in large quantity, and other changes. The tunnel is being driven in monzonite-porphry that is extremely hard.

DIVIDE.—The Gold Zone has mined 60 tons of ore showing free gold from the vein cut recently on the 700-ft. level. This vein was found on the surface a year ago when holes were being dug for telephone poles. It was barren at 500 ft., but some of the ore being extracted on the 700-ft. level is reported to assay \$150 per ton. The vein strikes directly toward the Alto, or at right angles to the main Tonopah Divide vein. Work has been resumed in the Alto and East Divide, on the 400-ft., or bottom,

level in each. The Alto was in ore on the 400-ft. level when work was stopped and a wide vein containing narrow seams of ore was being prospected at the same depth in the East Divide.

GOLDFIELD.—Report of the finding of an orebody in the Five to One tunnel, two miles south of the Florence, has brought hundreds of people to Goldfield from nearby towns in the last week. The report was untrue. A vein that outcrops on the hill into which the tunnel is driven was cut about 550 ft. from the portal. The foot-wall was entered and the vein has now been cross-cut 10 ft. without exposing the hanging wall. The formation is regarded as being promising and pannings of gold are said to have been secured in the vein. As the tunnel is in a part of the district where no work has been done at a depth greater than 50 ft., the Five to One has become the centre of interest. The Lone Star has given a permit for the erection of a Gibson mill to treat ore from the Meuli lease. The 3000-ft. shaft of the Deep Mines is to be three-

cross-cut is the junction of the extension of the South West Comstock vein and a contact between limestone and granite.

ARROWHEAD.—Negotiations have been started for the consolidation of companies owning claims adjoining and near the Arrowhead, Ely and Salt Lake City men to finance the deal, according to officials of the companies included in the plan. The Arrowhead has bought a 25-hp. hoist and steel head-frame, which will be in use by October, according to present plans. The Arrowhead is making regular shipments to the MacNamara mill in Tonopah, the ore coming from the 275-ft. level. The ore in a winze, recently started from the 100-ft. level, is 6 ft. wide and of this width 3 ft. is rich material that will be sent to a smelter.

UTAH

DALY-WEST AND JUDGE COMPANIES DECLARE DIVIDENDS

SALT LAKE CITY.—High honors were won by the

THE DAYTON DREDGE

compartment, instead of four, as was at first planned. Two of the compartments will be $4\frac{1}{2}$ by 5 ft. and the third will be 5 by 7 ft. in the clear, so that a skip can be used in it if found advisable. The collar of the old shaft, from which sinking will be started after it has been enlarged, is being concreted and concrete will be used to retain caving ground in the shaft, but elsewhere timber will be used. The company has enough timber on hand to start work and the rate at which the work will continue will depend on the arrival of more, according to H. G. McMahon, secretary.

CARSON.—The Nevada Protective, A. J. Canavan, superintendent, operating two miles north of Carson and eight miles from Virginia City, has started cross-cutting to the vein at a depth of 100 ft. The ore in the district contains gold, silver, copper, and lead. The first find was made in the South West Comstock, where a shaft has been sunk 210 ft. in ore worth from \$15 to \$20 per ton for a width of 4 to 6 ft., with assays of more than \$400 from seams. The objective of the Nevada Protective

Bingham team, composed of employees of the Utah Copper, Utah-Apex, and Utah Consolidated Mining companies, at the International Mine-Rescue and First-Aid Meet at Denver, September 9, 10, and 11, when the team tied for first place on artificial respiration work. The Bingham team lost in the drawing of lots and, consequently, must be considered second. Seventy-six teams, from all over the United States, Canada, and Mexico, were present at the meet, and fully 5000 spectators witnessed the events. The Spring Canyon Coal Co.'s team won the local prize as first from the State of Utah, while the United States Fuel Co.'s team was second. The meet was a great success, and did much to emphasize the importance of mine-rescue work in coal and metalliferous mines, as well as around mills and smelters.

PARK CITY.—The Ontario Silver Mining Co. has a force of men engaged in sampling the old mill dump, with a view to ascertaining the average value. If the returns are satisfactory, which it is confidently expected they will be, a method of working the dump will be decided upon.

There are several hundred thousand tons of material that will be workable. Report from the Park-Utah Mining Co. states that conditions in the mine are improving, but the great handicap is shortage of labor. Miners and shovelers are so scarce that it is becoming a serious problem how to continue operations. This is true not only at the Park-Utah, but at all of the other big properties in this district. Shipments from this district during the week ending September 11 totaled 1722 tons, of which the Silver King Coalition shipped 636 tons; Judge M. & S., 429; Ontario, 333; Daly-West, 115; Daly, 111; Nail-driver, 50; and J. B. Ireland, leaser, 38. During the previous week 2186 tons was shipped. During a severe electrical storm on September 7 the transformer house of the Three Kings Mining Co. was struck by lightning, which set fire to it and completely destroyed the building and its contents. The destroyed transformers belonged to the Utah Power & Light Co. The Three Kings company was compelled to suspend operations for a period of ten days while new equipment was being installed.

Directors of the Daly-West Mining Co. and the Judge Mining & Smelting Co. held their regular quarterly meeting at Salt Lake City on September 15. A 25-c. per share dividend will be paid to the stockholders of the Daly-West company on September 30. This will call for the payment of \$62,500, and bring the grand total of such disbursements up to \$6,768,500. The directors of the Judge Mining & Smelting Co. declared a dividend of 12½c. per share, payable September 30. This dividend will total \$60,000, and bring the grand total up to \$2,550,000. George W. Lambourne, president and general manager of both companies, reports conditions at the mines as excellent. The electrolytic plant of the Judge company is producing premium spelter, assaying 99.94% pure, and it is expected that during the coming month a new high record for production will be established. It is intended to operate two units of cells in the future, instead of one unit, as heretofore.

ALTA.—Mineralization of an important nature has been found in the 'Baby McKee' fissure in the lower adit of the Howell Mining Co.'s property, adjoining the Cardiff mine. About 18 in. of mineralized matter, showing iron sulphide, manganese, and low-grade lead ore has appeared in the face of the adit, according to H. J. Deming, secretary and treasurer. The lower tunnel is now in a distance of 2000 ft. For most of the way the tunnel has been in a hard quartzite. In several places, streaks and stringers of good ore have been opened up, some of which have assayed as high as 36 oz. silver, 10% zinc, \$1.50 in gold, and 28% lead. Recently conditions in the tunnel have been peculiar. The formation is quartzite, and in places the fissure, which takes an irregular course, is several feet wide and at others only a few inches. At present the face of this tunnel is about 300 ft. below the place where high-grade ore was found in the early days.

EUREKA.—Work is progressing satisfactorily at the Eureka-Lily mine, according to Grant H. Snyder, manager. In the drift headed south on the 1840-ft. level to tap the ore-shoot developed on the 1640-ft. level, bunches and stringers of ore have been continuous for a distance

of 150 ft. The ore-shoot on the 1640-ft. level was 250 ft. long, and a winze disclosed that mineralization improved with depth so the management decided to develop the same shoot on the 1840-ft. level. At the Tintic-Paymaster property, the work of cutting out a station preparatory to sinking a winze from the 400-ft. level, is nearly completed. The sinking of the main working-shaft at this property was discontinued on account of the heavy flow of water encountered, and a tunnel several hundred feet long was run on the 400-ft. level. The point where the winze is to be sunk is about 500 ft. from the shaft, and is in a limestone formation, which should carry no water.

During the week ending September 11, the Chief Consolidated shipped 29 cars of ore; Tintic Standard, 25; Dragon, 17; Mammoth, 12; Eagle & Blue Bell, 11; Iron Blossom, 10; Iron King, 6; Bullion-Beck, 6; Swansea, 6; Grand Central, 4; Gemini, 4; Victoria, 3; Centennial-Eureka, 2; Alaska, 2; Empire Mines, 2; Eureka-Hill, 1; Ridge & Valley, 1; Griggs-Huish Leasing Co., 1 car of concentrate; making a total of 142 cars.

H. G. Snyder, an official of the Tintic-Union company, owning ground in the eastern part of the district, states that work is to be taken up at an early date. The company recently levied a small assessment which will give ample funds for immediate needs. Some work will be needed in order to hold the claims for the present year, and officials state that they intend to sink a shaft in the near future. Recently the Zuma Mining Co. commenced drifting from the bottom of the winze which has been sunk about 100 ft. below the 800-ft. level. For the greater part of the distance the winze followed a small seam of ore and the same ore is exposed in the drift. The company is also raising from the 800-ft. level, where conditions equally as favorable exist. At the property of the Utah Zinc Co., situated in the Erickson district, west of this camp, ore is now being mined, according to B. F. Fleiner. The deposit is not large, but it is expected a larger vein will be found when the fissure is followed to the east-west break, a distance of only 50 ft. At present there is only a small force of men employed, but it is the intention to increase the number to carry on more extensive development during the winter. George Wallace is in charge. Regular shipments are now being made from the property of the Imperial Lead Co., and about 10 tons of lead ore is being shipped daily. The ore is transported by motor truck to the railway siding at Sugarville, and its average content is about 45% lead, with a small amount of silver.

OPHIR.—J. W. Cairns, one of the large stockholders in the Eureka-Ophir Mining Co., having valuable property in the Dry Canyon section of this district, announces that work will be undertaken again on company account. Mr. Cairns stated that the first work will be to clean out the workings of the property, which are in a run-down condition as a result of the leasing operations that have been conducted during the past few years. It is the intention to install a new hoist, compressor, and such other equipment as is necessary for steady production.

BRITISH COLUMBIA

DECISION AGAINST GRANBY COMPANY IN CASSIDY COLLIERIES LITIGATION.

VICTORIA.—The Supreme Court has given judgment for the plaintiffs in the suit brought by the Esquimalt & Nanaimo Railway Co. against the Granby Consolidated Mining & Smelting Co. for the coal rights in the area known as the Cassidy Collieries. The decision permits the Granby company to continue operations pending appeal which has been taken to the highest Dominion court and will finally be referred to the Privy Council. Final decision is expected next spring. The suit involves the legality of the grant by the British Columbian government under the Provincial Settlers' Rights Act, which was disallowed by the Dominion government after the grant was made. The Granby company has spent a million and a half in the development of these coal deposits

which the Government built recently to provide against such a disaster. The Granby company is planning the re-opening of its Midas mine, on Valdez peninsula. The mine contains fairly high-grade copper ore, but, on account of the long haul, it is proposed to concentrate before shipping.

SANDON. L. H. Biggar, a metallurgist of Montreal, who recently purchased Pat McGuire's interest in the Ottawa mine lease, has started the construction of a 50-ton concentrator. It is hoped to get the building finished before the snow comes, and then the heavy machinery will be hauled to the mine over the snow later. The Ottawa mine, which is situated at Slocan City, used to be owned and operated by the Consolidated M. & S. Co. Last year the company leased the mine to Pat McGuire and A. L. McPhee, who shipped 377 tons of ore to Trail. Much of this was derived from picking over the old dumps. The

DOME MINES, LTD., ONTARIO

and in building the town of Cassidy. The suit, however, does not involve the surface rights, and there will be no diminution of output until final judgment is rendered. This is important because of the decreased output of the Vancouver Island collieries which was 117,194 tons for August as compared with 140,512 tons for July.

STEWART.—At the meeting of the local branch of the Canadian Institute of Mining and Metallurgy, held here on September 1, E. E. Campbell, assistant manager for the Granby company, in an interesting paper on mining cost, stated that ore was being mined more cheaply at Hidden Creek than at any other mine in Canada. P. E. Petersen, manager of the concentrating department for the Granby company, described a flotation cell of his own invention that is giving good results on Hidden Creek ore. According to G. A. Young, road superintendent of the Atlin district, the bridge over the Bear river, at Stewart, is nearing completion and will be in operation shortly. Two miles of the road to the Stewart-Premier mine was washed out, and repairs are being pushed as rapidly as possible. He attributes the comparatively slight damage in the Alice Arm district to the wing-dam

Rambler mill has been re-started, after several months of idleness caused by the activity of the 'One Big Union'. The men now employed at both mill and mine are affiliated with the 'International Mine Worker's Union'. A new tunnel is to be driven on the Last Chance claim. The old Payne mine, which was one of the first mines to be operated in the Slocan, has been abandoned to a Seattle syndicate. It is understood that no cash has passed, but that a stipulation has been made that a definite amount shall be expended each year for four years and that 15% royalty is to be paid on all ore shipped. The upper part of the mine has been worked out, but the vein has been cut by a tunnel at a depth of 1500 ft. and little exploration has been done at this point, so the new syndicate will commence operations at that depth.

TRAIL.—The Consolidated Mining & Smelting Co. has declared the usual quarterly dividend or $2\frac{1}{2}\%$, payable October 1. The disbursement will amount to \$261,936 and will bring the total disbursement to \$7,121,083. During the week end September 7 a total of 7718 tons of ore was received at the smelter, the Consolidated company's own mines contributing 6946 tons. The other

shippers were: Emerald, Salmo, 45 tons; Josie, Rossland, 170 tons; Mandy, Le Pas, 371 tons; Nettie L., Gerrard, 18 tons; North Star, Kimberley, 125 tons; Payne, Sandon, 9 tons; Providence, Greenwood, 72 tons; Skylark, Greenwood, 16 tons; Taltarpin, Taltarpin, 4 tons; and Velvet, Rossland, 27 tons.

DOLLY VARDEN.—On September 10 this mine had shipped just over one million ounces of silver. In 1919 the production was 426,000 oz., the remainder having been shipped since June 17 of the current year. About 20 tons of 1000-oz. ore is being produced each month, the valuable minerals being native silver and argentite. Besides this high-grade stuff, the mine is yielding 235 tons daily of 37-oz. ore. It is hoped that there will be interruption to shipments until about December 15, when the snow will render the railroad ineffective.

ONTARIO

DECREASED PRODUCTION DUE TO SCARCITY OF LABOR:

TORONTO.—The Ontario government announces that it cannot at present see its way to build a branch railway from Swastika to open up the mining territory lying between Kirkland Lake and Larder Lake. Some time ago it promised to construct the line providing the companies interested would submit their properties to examination by government engineers and that the investigation showed that the resources warranted the outlay. The Associated Goldfields, the only company operating at Larder Lake, did not accept this condition, so the project failed. Now the Associated Goldfields declares its intention of building its own railway over a shorter route from a point at or near Boston Creek. The Kirkland Lake district has been supplied with a motor-road at a cost of \$100,000, a means of transportation that many of the mine-owners preferred to a railroad. A highway is now being built in the eastern extension of the field.

KIRKLAND LAKE.—The Kirkland Lake has cut its main vein on the 900-ft. level where it carries excellent ore with a showing of free gold. This working is the deepest in the district. The Buffalo-Kirkland has contracted for 1000 ft. of diamond-drilling to demonstrate the continuation at depth of veins uncovered on the surface. At the Wright-Hargreaves rapid progress is being made with the construction of the new 150-ton mill. Shaft No. 1 has been sunk to the 400-ft. level and the work of enlarging shaft No. 3 is in progress. Stopes are being cut at several levels in preparation for taking out ore. The Wood-Kirkland has brought in a boiler and hoist. The shaft has been put down by hand-steel for 40 ft., the vein showing improvement with depth. At the King-Kirkland camp-buildings have been erected and a series of strong and well-defined veins opened up on the surface.

PORCUPINE.—A new orebody, of excellent grade and width, discovered by diamond-drilling on the McIntyre about 1600 ft. below the surface, is thought to be an extension of vein 84 of the Hollinger, which last year yielded 137,000 tons of ore. The output of the Hollinger Consolidated has lately been considerably curtailed by reason of a shortage of labor. Owing to many men hav-

ing gone to help in harvesting, or to the lumber camps, the working-force has been reduced to about 900 and the mill is being operated at only half capacity treating 1600 to 1700 tons of ore per day as compared with the average for 1919 of 1950 tons per day. At the North Davidson where the construction of a steam-driven mining-plant has been completed, a vein on which a shaft is being sunk carries rich ore over a width of 4 to 5 ft. at a depth of 50 ft. The shaft will be put down to 150 ft. The main shaft on the Porcupine-Keora is down 250 ft., where cross-cutting has been begun to tap two veins indicated by diamond-drilling. The exploration of the north-west part of the North Crown property below the 1000-ft. level is proceeding rapidly. One hole is now 1600 ft. below the surface and has reached the Keewatin formation. The mill, which has a capacity of 150 tons, is running only at half speed owing to shortage of labor.

COBALT.—Operators who, when the price of silver was low, were storing their bullion, are now shipping large quantities. The bullion shipments from the Nipissing and the Mining Corporation of Canada last week totaled 550,715 oz. The Nipissing during August mined ore of an estimated value of \$238,959 and shipped bullion and residue from Nipissing and customs ore, having an estimated net value of \$701,981. A new record was made for the low-grade mill which treated 7691 tons. The Crown Reserve is drilling a hole from the 500-ft. level that will reach a depth of 1600 ft. below the diabase. On its claims in the Gillies Limit the company has a shaft down 30 ft. on a cobalt vein with encouraging showings.

Cyril Knight, Ontario Government Geologist, is re-surveying the geology of the Cobalt field. Work in the south-eastern part of Coleman township, including the Beaver and Temiskaming mines, has been completed and also that in the south-eastern part of Bucke township. Examination of the main part of the silver-producing area will be commenced immediately, but will be suspended during the coming winter with a view to resuming and completing the work in the summer of 1921. Bullion shipments reported from the Nipissing and the Mining Corporation for the two weeks ending September 10, amount to 449 bars containing 550,715 fine ounces.

For the first six months of 1920, silver production from Ontario decreased to \$5,077,028, as compared with \$5,951,362 during the first half of 1919. A further diminution is indicated by the present price of 94c. per oz. of silver, as compared with \$1.17 for the first half of the year. The 'Beaver Lake' vein on the Keeley Silver mines, in South Lorrain, has been cut at a depth of 425 ft. The width and mineralization so far determined compares favorably with the upper levels, where a large tonnage has been blocked out. There the vein has a width of four feet and contains 40 oz. of silver per ton. Financial arrangements have been made to operate the Cane Silver mines, comprising 120 acres situated on the Elk Lake branch of the T. & N. O. railway. Spectacular patches of silver occur in narrow veins at the surface and an effort will be made to make a carload shipment.

THE MINING SUMMARY

ARIZONA

The Coronado mine of the Arizona Copper Co. at Metcalf, in which a series of fires has occurred during the past three years, is now operating successfully under mine-fire conditions. One of the interesting features in connection with the operation of this mine is that the crew of men are working daily in safety some little distance beneath the timbered mat which is on fire. The mine is a vein-deposit of great length and is said to be one of the longest productive veins in the West. The main working tunnels are parallel to each other and to the vein. The method of mining formerly employed was top-slicing and a continuous timbered mat approximately a quarter of a mile long and 35 ft. wide extended over the main workings. The numerous fires, presumably of incendiary origin, by which this mine was troubled, all occurred in the timbered mat. At first these fires were extinguished, but new ones started faster than the old ones could be put out, and the task of completely extinguishing them became impossible. Some method of operating the mine in safety under mine-fire conditions had to be devised. When this decision was reached last fall, the mine, which had been sealed temporarily, was re-opened very gradually. Blowers were used to force the air through iron pipe, past an air-lock of double doors, thus building up a pressure of fresh air which forced back the smoke and gases in the tunnels. After all the operating drifts and tunnels were cleared the gases were forced through the caved and broken ground to the surface, a distance of approximately 700 ft. An evidence of the strength of mine gases upon reaching the surface, after passing through 700 ft. of caved and broken ground, is that the miners on the surface were driven from their work on top of Coronado mountain and a burro grazing in the vicinity was killed. After the mine had been entirely freed from gas a high-pressure blower of 60,000 cu. ft. capacity was installed on the 700-ft. level in the main working tunnel, the station, of course, being placed so as to allow the passage of trains with supplies, etc. As all raises immediately beneath the fire were filled with ore and sealed, the air-pressure from the mine fan reached the extreme end of the workings, where it prevented the smoke and gases from entering the newer stopes which were about to be opened. The system of mining was changed from the timbered top-slice system to the shrinkage method. The stopes were opened in the extreme western part of the vein, which was a long distance from the blower, and as this part of the vein became exhausted, the old stopes were allowed to close and new ones opened, gradually working toward the fresh air coming from the blower placed at the eastern end of the vein. Every safety precaution is used. Should the power go off accidentally and the blower close down, a large air-valve is opened immediately by the fan-tender, which allows a large volume of fresh air to enter the workings and maintain the pressure for a sufficient length of time to permit the men to reach a place of safety. Systems of signaling by means of horns, and telephones are provided so that a direct means of communication is always available. Aside from the safety point of view, the provision of an abundant supply of fresh air, as well as an immediate means of communication with the men, is very desirable for efficiency.

CALIFORNIA

Amador County.—Under an agreement with the Argonaut Mines Co., whereby the latter will bear all expenses, the Kennedy has started unwatering its property. This work will greatly aid the Argonaut company in clearing the bottom levels of both mines and will facilitate resumption of mining in the deep Argonaut levels much earlier than scheduled. The Kennedy company recently suspended all work at its property because of the expense attending unwatering and the unfavorable position of the gold market. The Argonaut company is anxious to clear all its workings and resume mining on the 4800-ft. level, where high-grade ore was disclosed shortly before the fire forced flooding of the workings.

The extension of the main orebody of the Central Eureka, recently opened from the 3900-ft. level, is reported to be developing the same high-grade ore that was found on the 3750-ft. and other levels. The vein is several feet wide. Twenty stamps are falling at the mill and other units will be operated as soon as sufficient power can be obtained.

Nevada County.—It is estimated that the power restriction is causing the Grass Valley mining district approximate loss of \$1000 per day in wages alone, as a result of the reduction in forces.

About 200 men were laid off. Their average wage was \$5 per day. According to the district superintendent of the Pacific Gas & Electric Co., no relief is yet in sight.

The North Star Mines Co. is engaged in re-timbering several of the old shafts on its property, including the Massachusetts Hill and New York Hill shafts. These shafts connect with the Central mine and are used for air and for pumping. All represent former mines now consolidated with the North Star properties.

The Sultana Gold Mining Co. has a crew of men engaged in wrecking several old mills and hoists on its property, including the old Sultana plant and the Prescott Hill plant. These plants are largely obsolete and have been replaced with a single modern plant.

At the Idaho-Maryland efforts are directed during the shortage of power at holding the water, it being impossible to make any gains. The water-level is now mid-way in the old canyon shaft. The new plans of the company call for unwatering the entire mine.

Shasta County.—Erection of the buildings at Winthrop by the Shasta Zinc & Copper Co. is proceeding rapidly and before winter sets in the management will have an excellent camp firmly established. Most of the structures have to be moved to the present site from Coram. The mine is being actively developed and construction of a modern zinc-plant is to start in the near future.

IDAHO

Coeur d'Alene.—The Federal Mining & Smelting Co., owning several properties in the Coeur d'Alene, is removing good ore from its Morning mine. The Gold Hunter is employing more men. Two shifts are employed on the Mid-night property where ore is being followed by raise. The Copper King is active. It raised 200 ft. from the tunnel-level but ran out of ore toward the top. The ore was recovered in a drift from the top of the raise and its appear-

ance is as good as in the raise. The American Commander is proceeding steadily with the exploration of its property. Work is being done on the surface and in a shaft with encouraging results. The company will add a compressor to its equipment in the near future.

That the rich ores of the Callahan-Zinc-Lead Co. in the Coeur d'Alene will go to a great depth is confirmed by the latest development, according to reports. The shaft is down to the tenth level, which is 1250 ft. below the main working tunnel. Cross-cutting to the vein is in progress and indications are that the same fine conditions will be found that were opened on the ninth level 200 ft. higher. The shaft is down to the level of Beaver creek and as the ore persists in the same large orebodies and of the same high quality, it is believed it will continue to much greater depth. One of the most important developments in the last year has been the building and equipment of the mill of the Nabob Consolidated Mining Co. on Pine creek. The mine is now operating with one shift, but will increase to full force in the near future. James Carney, veteran prospector and mine owner, who located the Carbonate Hill, Carney Copper, and Elizane Carney Copper properties 30 years ago, is still working the Elizane and says the Carbonate Hill, which he recently visited has a good showing for a big mine. He has started a lower tunnel on the Elizane Carney Copper Mining Co.'s property, which lies north of the Carbonate Hill.

Mullan.—"Highly encouraging conditions have been disclosed by the West Hunter Mining Co., one mile north of this place, in developing on the No. 2 level," says T. B. Cosgrove, manager. "The disclosure is contained in a streak of ore two inches wide opened at a depth of 100 ft. The width of the ore increased on drifting and at the face of the drift, 200 ft. from the place of beginning, is 18 in. wide. The average value is \$31.70 to the ton, mainly in lead and silver but including \$2.50 in gold. The vein is 10 ft. wide. The section of the vein containing ore should be reached in 200 ft. of cross-cutting on the main-tunnel level which is 850 ft. below the No. 1. Operations have been transferred to the cross-cut which is being advanced at the rate of four feet per day."

Wallace.—The ore in the new find at the Bryan has been cross-cut 15 ft., but the wall has not been reached. The entire 15 ft. is in good milling-ore. The Federal Mining & Smelting Co. has applied for a writ of certiorari, and if it is granted the Supreme Court will review the entire case of the Star Mining Co. against the Federal company. The Sunset mine is being unwatered to the 800-ft. level so as to permit access to the West Sunset. It is rumored that the Days may buy the Sunset from W. A. Clark.

NEW MEXICO

Pinos Altos.—The Hecla Divide Mining Co., which recently acquired the interest in the Langston mine formerly held by the Mexarco Mines Co., has a force of men at work repairing the mine workings for operation. H. F. Davis is superintendent.

MEXICO

Considerable interest is being evinced over the international exposition at El Paso, October 4. The principal officials of Chihuahua are expected to be present and several carloads of ore are to be shipped from the Chihuahua mines for the mineral exhibit which will be one of the best of the exposition. Parral, Torreon, and Durango will also be represented.

El Oro.—The Esperanza mine has recently cut the Descubridora vein on the fifth level. The vein at this point is four feet wide and assays 0.73 oz. gold and 38.48 oz. silver per metric ton. The manager stated in June that there remained about 1000 ft. on the course of this vein that had not been explored. Until this ore was found the mine had very little high-grade ore in sight and was depending on low-grade ore and old fillings which can only be handled on a large tonnage basis.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

George Alton has moved from Reno to Idaho Springs.

S. J. Lewis has returned from Zacualpan to Mexico City.

W. H. Harrison, of Washington, is at Duluth, Minnesota.

Bond Coleman has moved from Mexico City to Mound City, Kansas.

E. Wright Crow is now stationed at Metaquesuintla, in Guatemala.

H. H. Schlapp, of Melbourne, has been on a visit to his former home at Davenport, Iowa.

Otis D. Welsch is mill superintendent for the Saltchuck Mining Co., at Ketchikan, Alaska.

Scott Turner, after a visit to New York, has gone to The Pas district of northern Manitoba.

F. A. Dalburg, of New York, is now with the West India Oil Co., at Caracas, Venezuela, South America.

Gustave A. Overstrom sailed by the "Tenu Maru" for Korea, in the interest of the Seoul Mining Company.

George Blagewitch, a Russian mining engineer from the Ural region, is visiting mining and metallurgical plants in Utah.

J. I. McGeorge, for a number of years past assayer for the Silver King Coalition Mines Co. at Park City, Utah, has resigned.

E. J. Raddatz, president of the Tintic Standard Mining Co. at Eureka, Utah, has been in southern California for a vacation.

Morris B. Parker has resigned as consulting engineer to the California Rand Silver Mining Co. and is now at Hollywood, California.

Francis B. Laney, of the U. S. Geological Survey, has been appointed Professor of Geology in the School of Mines of the University of Idaho.

Henry Leighton, professor in the University of Pittsburgh, has been examining pyrite and iron-ore deposits in the Algoma district, Ontario.

A. W. Beam, president and manager of the Benguet Consolidated Mining Co., sailed by the "Tenu Maru" on September 18 for the Philippines.

H. G. Jensen, of the U. S. Geological Survey, Washington, is in San Francisco for a month to investigate the copper-mining industry of the Pacific Coast.

Robert D. Longyear, geologist for the E. J. Longyear Co., has just completed a geological examination for the Yellow Pine Mining Co. at Goodsprings, Nevada.

Karl F. Hoffmann has severed his connection with the General Development Co. to undertake independent work with offices at 2 Rector street, New York.

S. F. Shaw has resigned as superintendent for the American Smelting & Refining Co., to become manager for the Compania Minera La Constancia at Sierra Mojada, Coahuila, Mexico.

E. Harold Walker, safety engineer at the Utah Copper mine, at Bingham, has resigned to accept a position with the Union Minière du Haut Katanga, at Elizabethville, in the Belgian Congo.

Raymond J. Poole, Professor of Botany in the University of Nebraska, has completed investigations, begun in May, of effects of smelter fume on plant life in the vicinity of the smelter at Murray, Utah.

J. E. Healey, general manager for the Consolidated Main Reef Mine & Estates, Ltd., Johannesburg, Transvaal, is at Los Angeles. He will visit San Francisco, Denver, and Chicago before returning to New York, whence he sails for London by the middle of October.

ZINC

*Issued by U. S. Bureau of Mines.

Eastern Metal Market

New York, September 15.

The markets are all generally featureless and quiet. The tendency of prices is downward if any change is recorded.

Buying of copper is very light, but inquiries from large consumers are increasing. Prices are easy.

The tin market has been quiet with buying only moderate and prices but slightly changed.

Lead imports continue to cause a softening tendency and prices are lower.

The zinc market is uncertain as to the future because of the improved situation. Values have declined.

Antimony is slightly higher but not active.

IRON AND STEEL

Business in general is very quiet. Traffic conditions are improving very rapidly and this is considered as the main reason why the Steel Corporation's unfilled orders as of August 31 showed a decrease for the first time in several months. The pig-iron market is stagnant. Buyers are not ready to take hold for next year and sellers are contracted for this year. It is believed that prices have marked their peak for this movement. What buying there is appears to be mostly in malleable iron in the Pittsburgh district. There has been some lifting of embargoes, which has benefited the Youngstown district, where pipe and wire products are most in demand. Demand for plates and shapes is light but consumers of nuts, bolts, and wire are active. The movement of coal is better, which is a source of satisfaction. Prices of coke remain stiff as output declines and car supply grows less. There has been a wage reduction in sheet-mill operation for the first time in a long period, due largely to a letting down in the automobile business.

COPPER

The market is lifeless as to actual business, but there are indications that buying by large consumers must set in soon. This is based on the fact that the latter are sounding the market frequently and in large numbers. The predicted buying movement is now set for the last of September or the first part of October. In the meantime large producers as a class do not have any set price. A few still adhere to the 19c. level, while some are selling at 18.75c., New York. In the outside market there are small producers and dealers who will take business at 18.75 to 18.50c., New York. In the mixed situation we quote the market for both Lake and electrolytic at 18.75c., New York, for September delivery, with 19c. asked for October and in some cases third quarter. Export demand is said to be very good. The July exports were 19,232 tons, excluding those to Canada, which should bring the total to over 20,000 tons.

TIN

The market is still quiet. The tin importers, to whom we referred a week ago, have continued to make some sales of future shipments to dealers and consumers, principally the latter, and the sellers are not reported as busy. In fact the most encouraging feature of the market has been the buying by consumers, among whom have been some large tin-plate makers, and this is felt to be significant. The tonnage involved is reported to have been considerable. On the New York Metal Exchange there have been further sales under the rule. Total sales for the week on the exchange have been about 250 tons. Spot Straits, New York, has been steady around 45c. and yesterday was quoted at 45c., New York. Arrivals thus far this month have been 2700 tons with 4675 tons reported afloat.

LEAD

The market continues quiet. It is admitted even by some producers that demand is not heavy and that consumption

is on the decline. The principal market even of the week was the reduction on Monday of the leading interest's price $\frac{1}{2}$ c. per pound to 8.25c., St. Louis, or 8.50c., New York. This was not unexpected by some, although declared unlikely by others, principally producers. The step was merely readjustment of the trust's price to the market-level, which has been lowered still further by imported lead. This has already amounted to at least 10,000 tons, it is stated, and sales have been made as low as 8c., New York, duty paid. In fact with exchange at \$3.48 per pound sterling and the London price at £35 per ton, actual import cost with duty at 25% ad valorem figures at 7.40c. per pound, New York, which means a good profit. We quote the market as 8.25c., St. Louis, or 8.37 $\frac{1}{2}$ c., New York, for early delivery under present conditions.

ZINC

There are indications that the import situation is a factor and will continue to be a lessening factor and is nearly at an end. Re-sale metal from England is still available and at a lower level than a week ago. It is quoted at 7.75c., seaboard, for prime Western. The tone of the domestic market is better. There are more inquiries from galvanizers and some have resulted in sales at 7.85c., St. Louis, for early delivery. This would mean 8.30c., New York, with the cost of freight added. It is, however, possible for imported zinc to compete at Pittsburgh with prime Western at 7.80c., St. Louis, which appears to be the present market. The New York market may be quoted as 7.80c. on the basis of the import situation.

ANTIMONY

The market is quiet but strong. There are no features. Quotations for wholesale lots for early delivery are 7.12 $\frac{1}{2}$ c., New York, duty paid. Jobbing lots are $\frac{1}{4}$ to $\frac{1}{2}$ c. higher.

ALUMINUM

The feature of this market is the heavy offering of foreign virgin metal, which can be had as low as 30c., New York. The leading interest continues to quote the same brand at 34.90c. f.o.b. producer's plant.

ORES

Tungsten: No new business is reported but the outlook is said to be more promising. Prices are nominally unchanged at \$5.25 to \$5.50 per unit in high-grade ore, with Chinese ore at \$5 per unit. For Bolivian, \$6 to \$7 per unit is asked.

Molybdenum: The situation is unchanged with regular concentrate quoted at 75c. per pound of MoS₂ contained.

Manganese. There are no developments. The market is quiet and easy. Consumers are apparently well stocked and are unwilling to pay more than 55c. per unit, seaboard, while sellers are asking 65c. Imports in July were 18,447 tons, or the lowest in several months.

Manganese-Iron Alloys: These markets are stale. There is very little inquiry and very little selling. The recent cut in ferro-manganese has caused consumers to wait, as usual. Quotations are unchanged at \$170, seaboard, for British alloy, with American on the same basis. There are predictions that the domestic producer may cut the British price. Spiegeleisen is quiet but strong at \$80 to \$82.50, furnace, depending on the grade.

The Anaconda Copper Co. for the first time in its history is preparing for the recovery of lead in its Montana smelting plants. One of the old Boston & Montana reduction-works stacks at Great Falls has been converted into a lead stack for the treatment of the residue from the electrolytic-zinc plant and the lead recovered from these residues will form no small credit to operating expenses.

Book Reviews

Exporter's Gazetteer of Foreign Markets. Compiled by Lloyd R. Morris. Pp. 709, ill., index. Johnston Export Publishing Co., New York.

While primarily intended for the exporter, this book contains so much interesting and useful statistical and miscellaneous information regarding the countries of the world as to make it a valuable general book of reference.

A Spanish Mining Directory. By Adriano Contreras and Ramon Oriol, mining engineers. Vol. XX, 1920. Pp. 1300, cloth. Revista Minera, Metalurgica y de Ingenieria, Villalar 3, Madrid.

This book (in Spanish) bears the title 'Anuario de Minería, Metalurgia, Electricidad y demas Industrias de España' and contains a classified list of all Spanish mines, mining and metallurgical companies, scientific societies, mining and civil engineers, copies of the mining laws, and much other information interesting and useful to those engaged in the industry.

A Vocabulary of Russian-English, English-Russian Mining Terms. By C. W. Purington and G. Toderovich. Pp. 126. J. B. Lippincott Co., Philadelphia. For sale by 'Mining and Scientific Press'. Price, \$2.25.

This little book has been compiled largely as a result of Mr. Purington's engineering experience in Siberia. Most of the terms given apply to mining and geological subjects, but in addition some from mechanical, electrical, and chemical nomenclature are included as well as some relating to travel, law, and finance. The book is 3 by 4 in. and can be used conveniently and practicably by engineers whose work carries them to Russia.

Structural Steelwork. By E. G. Beck. Pp. 459, ill., index. Longmans, Green & Co., London and New York. For sale by 'Mining and Scientific Press'. Price, \$7.50.

This is a good book on structural-steel design and construction from a British standpoint, and an excellent one for a British engineer to buy. On the other hand, while the points of difference between American and British practice are relatively unimportant, nevertheless, they do exist. Consequently we do not believe, unless he wishes to inform himself of differences between practice in the two countries, that the American engineer will have much use for the book, well written as it is.

The Ownership and Valuation of Mineral Property in the United Kingdom. By Sir Richard Redmayne and Gilbert Stone. Pp. 256., ill. Published by Longmans, Green & Co., London. For sale by 'Mining and Scientific Press'. Price, \$4.50.

This is an elementary treatise on the nature of mineral interests and royalties, and the correct method of valuing such property for the purposes of sale, probate, rating, and taxation, together with a statement of the law relating to rating and taxation. Sir Richard Redmayne formerly was Chief Inspector of Mines and is otherwise well qualified to write on the subject.

The Business Man and His Bank. By William H. Kniffin. Pp. 273, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

Most books on banking are written for the banker or the bank employee. This one is written for the depositor and

the borrower. Besides the ordinary commercial banks and savings banks, other organizations performing some or all of the functions of banking are discussed, although most of the space is naturally devoted to the ordinary commercial bank, or bank of discount. The important features of the various kinds of business that may be done between a bank and its depositors or borrowers are discussed in turn. The book will be of interest to anyone having dealings with a bank, and, particularly, to the man in business for himself.

The Oil Shale Industry. By Victor Clifton Alderson, Sc.D., President of the Colorado School of Mines. Pp. 175, ill. Published by Frederick A. Stokes Co., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

This is a timely volume on an interesting subject by a competent writer. It contains many valuable statistical, mining, and chemical data on the production and refining of oil-bearing shale. Nobody interested in the subject can afford to be without it. Although unduly optimistic in its appraisal of the commercial outlook for this new phase of the oil industry, the book is an extremely useful compendium of information on oil-shale. It is criticized by the editor on another page of this issue.

Tin, Sheet-Iron and Copper-Plate Worker. By Leroy J. Blinn. Pp. 319, ill., index. Henry Carey Baird & Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

About half of this book is devoted to practical directions for cutting patterns for all kinds of sheet-metal work, and to a summary of the principal propositions of plane geometry of importance in such work. The rest of the book is a curious hodge-podge of mathematical tables, directions for tempering, receipts for varnishes, lacquers, cements, and solders, and considerable other miscellaneous information. There is a good index, however, which goes a long way toward making up for the lack of arrangement of the book itself. Furthermore, the material, although the arrangement is disorderly, is almost without exception of such a character as to be useful to the sheet-metal worker, who will find the book, in spite of its defects, well worth while.

The Iron Ores of Lake Superior. By Crowell & Murray. Pp. 300, maps and tables. The Penton Publishing Co., Cleveland, Ohio. For sale by 'Mining and Scientific Press'. Price, \$5.

This is the fourth revised edition of this standard reference book on the iron-mining industry of the Lake Superior district. The material presented is a mixture of technical, statistical, historical, and commercial information that gives a comprehensive survey of the iron industry in all its aspects. Too frequently mining companies are unwilling or at least indifferent as regards the supplying of information relative to their operations. Fortunately those in charge of the mines on the iron-ranges appear to have co-operated splendidly in furnishing the data necessary for the preparation of this volume. One chapter describes a method of mixing ore for shipment, a process that requires increased attention as the better grades of ore are being depleted. This also involves systematic methods for recording analyses and this phase is treated in a separate chapter. The book contains maps of all the ranges, and it is further illustrated with vertical sectional views showing the geological formations of the principal ranges. The tables include the record of ore-loading docks on the Great Lakes, shipments from each range since its opening, prices of iron ore at lower-lake ports since 1855, rail freight-rates from the mines to lake shipping points, and cargo-rates since 1855.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE DAYTON DREDGE

The Bethlehem Shipbuilding Corporation, Ltd., builders of the Dayton, Nevada, dredge, advise us that this dredge which started operations on September 6 is all-steel throughout, having a steel hull 108 ft. 5 in. long, 46 ft. wide, and 8 ft. deep; the buckets are 9 cu. ft. capacity and the dredge is designed to dig 39 ft. below the water-level. The machinery was made from parts from Marysville No. 3 and No. 4 dredges, with slight alterations. The revolving-screen is 6 ft. diameter and 38 ft. long, of the usual construction. The gold-saving table-area has been greatly increased over that of Marysville No. 3 or No. 4 and the distributing-box is of new construction, which will give better distribution of fine material.

All framing, including the housing, is steel throughout, and the covering is asbestos-protected metal so the dredge is absolutely fire-proof, no fire-insurance being necessary.

All deck-plating is electrically welded, this being the first dredge of the size, known to us, that has an electrically welded deck. The gantries have Bethlehem I-beams and girder-beams, which work in very nicely for this construction. The spuds are made of Bethlehem beams with cover plates, all bolted together.

Great care was taken in designing this hull and superstructure so as to give the maximum amount of strength with the minimum amount of weight. A considerable saving in weight has been made over the steel hulls of previous dredges of the same size.

'SURE SHOT' MINE-CAR COUPLER

The 'Sure-Shot' mine-car coupler is a new device manufactured by the Electric Steel Co. of Indianapolis. This coupler is coupled instantly by bumping the cars together after the outer link has been placed in position. The coupler is made of electric steel which has been heat-treated

and is practically indestructible according to the claims of the manufacturer. One of the features of the coupler is that it will act on sharp curves and uneven tracks and with a big saving of time. The safety feature of the coupler is also one of importance because by its use accidents in car work are reduced to the minimum. The design of the coupler is quite simple as will be noted by reference to the illustration. There is only one moving part and that is the drop-dog. The links and pins are all refined iron. The couplers are furnished complete with links and pins assembled and ready for immediate use. Holes for attachment to draw-bars can be bored or drilled to suit the requirements.

MINERS' SAFETY HAT

The miners' 'Hard Boiled' cap, which is being featured as a safety device by E. D. Bullard, of 268 Market street, San Francisco, has attracted the attention of the California Industrial Accident Commission and is made the subject of an article by H. M. Wolfkin in a recent issue of the 'California Safety News', a paper published by the Commission.

Wolfkin calls attention to the number of head injuries incurred by miners, steel erectors, shipbuilders, and workers in similar lines, and says that heretofore the only available protective caps were too expensive, too heavy, and too uncomfortable to be generally adopted. In the case of the 'Hard Boiled' cap, however, he points out that it weighs only nine ounces, that it is comfortable and inexpensive, and that it is a real safety device.

He cites a number of actual instances to prove that the cap is a real protection to workers. One case was where a twelve-pound joining-iron fell six feet, striking the head of a shipyard worker who was wearing one of the caps. The man was knocked to his hands and knees, but was not injured, and the cap was not damaged. Another case was at the Moore shipyards, where a four-pound piece of angle-iron fell twelve feet, striking a workman squarely on top of the cap. In this case, also, the man was knocked to his knees, but not injured.

COMMERCIAL PARAGRAPHS

W. L. Chandler, purchasing agent for the Dodge Sales & Engineering Co., is a candidate for the presidency of the National Association of Purchasing Agents.

At a meeting of members of the welding trade in Chicago, held in the rooms of the Western Society of Engineers, on Tuesday, August 3, a Chicago section of the American Welding Society was organized. There were about 75 in attendance, representing many railroads terminating in Chicago and also many of the larger local industries. The following officers were elected: chairman, M. B. Osburn; vice-chairman, O. T. Nelson; and secretary-treasurer, L. B. Mackenzie. Meetings will be held on the second Tuesday of each month in the rooms of the Western Society of Engineers and those interested in the subject of autogenous welding, by all methods, are invited to attend. The address of the secretary-treasurer is 608 S. Dearborn street, Chicago.

The new 'Eveready' instruction book, put out recently by the Oxweld Acetylene Co., 3640 Jasper place, Chicago, is one of the best treatises on every-day oxy-acetylene welding and cutting that has thus far been produced. Not since the company issued its 'Oxweld Manual', which has gone through two complete editions, has Oxweld experienced such spirited demand for a trade publication. The little volume is a compact and handy brochure (5 by 8 in.) containing 55 printed pages, inclusive of illustrations and drawings. It covers the field of everyday applications in a remarkably clear and concise treatment and in language that is easy for the beginner to grasp, and it is at the same time invaluable to the experienced welder and cutter. The booklet is distributed free.

MARCY ROLLER MILL

THE Marcy Roller Mill represents a high development in grinding machinery and in this respect is in the class with the Marcy Ball Mill.

The open end feature, through which the conditions within the mill may be observed while running, brings about low cost of operation.

Rods or rollers can be used in a tube mill but for the best results, *bent and broken rods must be removed.*

High efficiency in the roller mill is obtained by the low pulp line as in the Marcy Ball Mill.

Thirty six large size Marcy Roller Mills are now being manufactured for one of the large mining corporations of the Southwest.

We will be glad to advise on your crushing problems

T. A. RICKARD, . . . Editor

EVIDENTLY the Australian author of the article appearing in our issue of September 18 was misled, by the position of a crane over the Marcy mills in the Inspiration mill, into supposing that this mill has to be moved from its bearings before it can be re-lined. This is not the case, and we are glad to make the correction, now that our attention has been drawn to the error. The re-lining can be done in place and without difficulty.

ON August 17 the twenty-fourth anniversary of the discovery of gold on the Klondike was celebrated at Dawson under the auspices of the Yukon Order of Pioneers. The occasion was rendered remarkable by the fact that it coincided with the arrival of four aeroplanes on their flight from New York to Nome. After all, there are things more wonderful than finding gold, even in quantity equal to a king's ransom. In 1896, when the squawman, George Carmack, stumbled upon the alluvial gold of Bonanza creek, the automobile was just coming into use. Flying ceased to be an eccentricity thirteen years later. What a difference aviation would have made to the Klondike rush of 1898! Undoubtedly if the discovery of rich gold placers were to be announced today from any remote or inaccessible corner of the earth, there would be none of the painfully laborious pilgrimage of former times, such as that which broke the heart and health of hundreds among those who climbed the White Pass above Skagway and trudged wearily to Dawson twenty-two years ago; instead there would be throbbing of engines in the air and the determined flight of planes across the waste of land and water separating the cities of civilization from the new Eldorado. We hope to live to see it.

TO the American miner it is almost annoying to read about the premium paid on the gold produced in other countries. Here is the Australian Gold Producers Association announcing that the total amount distributed among its members on account of the premium "earned" on gold exported from Australia since March last year is £1,064,646, "of which the greater share was credited to the Western Australian mines". "Earned" it, did they? It was a gift that they owe to a combination of circumstances, and more particularly to the appreciation of our good old dollar with that fine old bird, the American eagle, upon it, whereby it commands a rate of exchange that calls for 110 Australian shillings in lieu of the 84 that formerly sufficed. Pleasantry apart, we envy those

Australians; what a bully thing that premium is! It sweetens the life of the gold-miner just at a time when he needs, and deserves, a cheerful tonic. We read further that "an interim dividend on the gold exported from Australia during the first quarter of this year amounted to £237,316". Whether the pound sterling be worth more or less, that dividend looks good to us. Curiously enough it is due entirely to the fact that the British pound is worth only \$3.50 just now. "It is an ill wind that blows nobody good."

FLOTATION is not applicable to all ores. It is important therefore, particularly to those about to devise a metallurgic scheme, to ascertain to what extent the process of froth concentration is suitable. In this issue we publish an article that will aid anyone so situated. The testing of ores, for the purpose of determining their amenability to flotation, is discussed by Mr. James M. Hyde, now professor of metallurgy in Stanford university and formerly associated intimately with both the introduction of flotation into this country and the subsequent litigation over patent-rights. Professor Hyde has the art of exposition; he writes clearly; we feel sure that the suggestions he offers will be keenly appreciated.

SHARES of the Alaska Treadwell Mining Company have risen recently on the London market from 10 shillings to £2, a quadrupling of price since the slump that followed the collapse of the workings, due to caving and flooding, three years ago. As our readers are aware, most of the stock is held in London, a reminder of the time when the Exploration Company, under the leadership of the late Hamilton Smith, controlled the enterprise. The recent rise, it is interesting to note, is due, in part, to the buying of shares by people on the ground, that is, at Treadwell and Juneau, these purchases being stimulated by favorable news concerning the development of the group of prospects that the company has under option. This property consists of 31 mining claims on Roundabout mountain on the Nixon fork of the Kuskokwim river, at a place 35 miles from the little settlement of McGrath, which is a station on the Government wireless telegraph; the mines are 12 miles from the Kuskokwim river, a broad stream and navigable from this point to Bering Sea, which it enters below the little port of Bethel. Another way of indicating the locality is to say that the mines are 150 miles west of Mount McKinley. They have been taken under option for periods ranging

from four to five years, the optionees including not only the three Douglas island companies, namely, the Alaska Treadwell, Alaska United, and Alaska Mexican, but also the Bunker Hill & Sullivan company, which is under the same general management—of Mr. F. W. Bradley—as the three contiguous mines at Treadwell, on Douglas island. The claims are located on a limestone-granite contact for a length of two miles. Along this contact there is a lode-channel in which lenticular bodies of ore have been found. The ore is valuable chiefly for gold, but it carries two or three ounces of silver, and some of it contains from 2 to 8% copper. The surface is covered with moss and frozen mold—the tundra—as is usual in the North, so that prospecting is confined mainly to exploration underground by means of drifts and cross-cuts. Several lenses of ore have been disclosed; they consist of high-grade ore; for example, 38 feet assaying \$56 and 32 feet assaying \$65 per ton. A large proportion of the ore assays between \$30 and \$35 per ton, for a full stoping-width, but the orebodies are comparatively short, for example, 40 to 60 feet. The workings are only 100 feet deep as yet. The men employed are mostly the owners of the claims themselves; they constitute an excellent working force; 19 of them are engaged in actual mining, but this number is to be increased to 35. The latest letter received in San Francisco is dated June 4, which gives an idea of the comparative remoteness of the region. At that time the ice on the river was just breaking and snow was still on the ground. Mr. Livingston Wernecke, a competent geologist and engineer, is in charge of these operations. It can be said that the rise in the shares discounts the probabilities, but the venture is promising, and it is much to be hoped that it may give the Treadwell companies a new lease of industrial life.

MORE than 20% of all the taxes paid in the State of Montana during the last three calendar years was paid by the Anaconda Copper Mining Company, according to a recent statement by its president, Mr. Cornelius Kelley, to the Montana Bankers Association. There is material for thought in this fact and in the additional statement that the Anaconda company, the Montana Power Company, and the five railroad corporations doing business in the State, together pay 43.29% of all the taxes. This does not include income-taxes or taxes paid elsewhere. There are other corporations doing business within the State; in fact, a recent dispatch announced that the total assessment of the three big power companies (including the Montana Power Company) has been raised \$4,000,000. It would seem that Montana is approximating that ideal socialist condition in which all the expenses of government are paid by the large corporations. According to Mr. Kelley, the Anaconda company has earned \$494,317,000 within the confines of the State during the last eight years and has expended in Montana, for supplies, wages, and miscellaneous items, more than 80% of this total. He does not say how much of the remainder went for similar expenditures outside the State, and even socialists would have to pay for the use

of money derived from exterior sources. Information like this is useful. We would like to see the Anaconda company issue a statement showing what proportion of the five hundred millions went to labor. We do not mean that item of the operating expenses which reads 'salaries and wages' and amounts to about 45% of the total, but rather that item plus all the other items that go to make up the real total, such as the item of wages in the freight charges, which amounts to about 50% of the cost of hauling the coal and coke, and the item of wages in the cost of the materials consumed in the hauling of the freight; and the wages in the original cost of the coal, which is about 75%. As an additional statement we would like to see the amount of dividends distributed to stockholders who are wage-earners. On account of the diversified interests and because it produces many of the raw materials used in its operations, these statements concerning the business of the Anaconda company should be instructive; they would, we think, have more value in counteracting I. W. W. talk than any dry argument based upon any bare economic theory.

Mining Finance

In this issue Mr. Robert S. Lewis, Professor of Mining in the University of Utah, discusses the principles underlying intelligent methods of finance, and their application to the business of mining. For success in politics, as we know, it is best to be born in Ohio, but to be successful in finance it is desirable to 'come from Missouri'. The sagacious citizen wants 'to be shown'; he eliminates the factor of uncertainty as much as possible, and if there be in his scheme or enterprise an element of doubt, as usually there is, he expects a return in proportion to the risk. In business, as in life generally, the first requisite is intellectual honesty, that is, an avoidance of self-deception. It is as sane to speculate as to invest, so long as the probable gain is proportioned to the probable hazard; that applies to mining, which usually is attractive to intelligent men because the danger of losing their money is compensated by the chance of a big winning. The same reasoning applies to the promoter. As Professor Lewis says, it is not wrong to offer stock in a gamble provided the conditions are stated truthfully. Even the wild-cat is a legitimate form of enterprise when its real character, as a risky venture, is set forth frankly. Misrepresentation is the essence of fraud. When a fiscal agent, as the shady promoter calls himself, represents a gamble in oil-drilling as "a manufacturing proposition" or a gold-mining prospect as "a gilt-edged investment" suitable for a ten-year lock-up, he is lying. Occasionally he believes his own lie because he has told it so often in highly persuasive language, but more commonly he lies with an unwinking eye. Professor Lewis gives avarice as the fourth cause of over-capitalization; but it is much more than that; it is the primal cause of shady finance. If people were not greedy as well as gullible there would be no need for blue-sky laws. These do not succeed completely in preventing the perpetration of fraud because no legislation will deter the fool from

parting from his money, particularly when he expects something for nothing, that is, a big return for a small risk, a potentiality of wealth for a car-fare. Indeed the selling of stock at two or three cents per share is itself a fairly trustworthy sign of something wrong. It is bait, not fish. The issuance of low-priced shares is meant to catch people of small means; it should be discouraged, because people of small means should not risk their savings in ventures that are hazardous. They ought to put their money in a savings bank. Mining is for grown men, not widows and children; it is an adventure involving a risk that should be faced only by those not likely to be broken by failure; its rewards are to be won only by those able and willing to incur danger; it is profitable largely in proportion to the financial peril inseparable from an industry in which a factor of uncertainty is implicit. The wise man expects a return proportioned to the risk, the simple one ignores the risk and is content with a 'manufacturing profit'. For example, the promoters of the big mining companies of the Rand risked their money on a 25% return and then boosted their stocks until the dividends represented 6 or 7% on the market valuation, by which time they recommended them as trust investments for widows and orphans. The result was that the public got the stock at an inflated price, on which no real profit was possible, while the insiders retired into dignified opulence, solacing themselves with slow horses and fast women, while their successors endeavored vainly to justify expectations that were founded on falsehood. Such performances are not peculiar to Johannesburg, Hamburg, or London; we have seen them duplicated in this country; wherever and by whomever done, they are no part of legitimate mining, but parasitic growths upon an honest industry. The sooner they are recognized as thievery the better.

The Deepest Mine

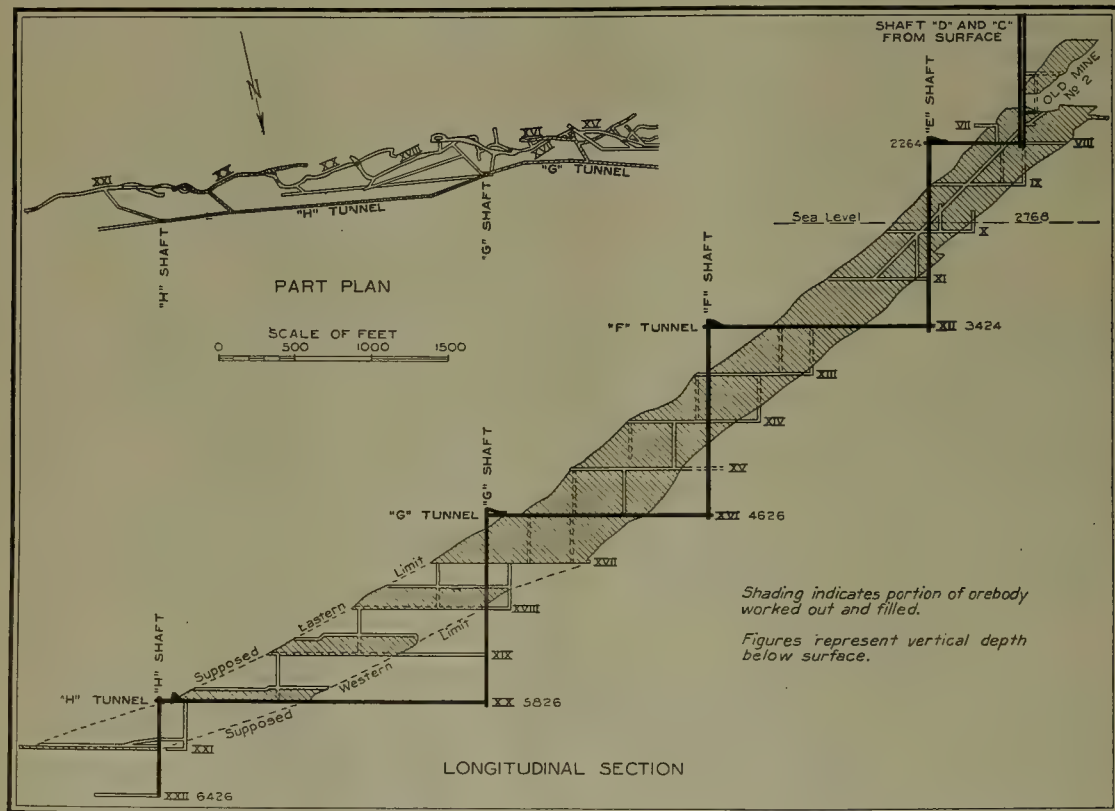

The deepest mine in the world is the Morro Velho, a gold mine in the province of Minas Geraes, in Brazil. It has reached a depth of 6426 feet. This alone would make it interesting; but it presents other notable features, among which may be mentioned its continuous management by Mr. Charles Chalmers and the curious character of the mining methods by which it has been developed. The St. John del Rey Company, which owns this mine, was formed in 1830, ninety years ago. Mr. Chalmers has been in charge since 1884. The yield to the end of 1919 has been 6,940,000 tons from which £13,350,000 worth of gold has been won. An average of half an ounce is a sweet thing in gold mining. Last year the output was 166,000 tons, yielding 105,537 ounces, from which were paid dividends amounting to 10% on 546,265 ordinary shares of £1 each and 10% on 100,000 preferred shares of £1 each. The amount received as premium on gold was £61,635, which, however, was almost wiped out by the rise in Brazilian exchange. Owing to a war-time embargo upon exportation, the gold had to be sold to the Brazilian government, instead of being shipped direct to London. The increase of temperature

in depth has been a serious obstacle to efficient labor and is rendered all the more serious by the indirect system of openings underground, rendering it difficult to establish a satisfactory system of ventilation. The accompanying section shows the step-like series of shafts and levels by which the bottom of the mine is reached. There the temperature of the rock is 117°F., and of the air 110°. When first entered the temperature of the rock at 6400 feet was 118°, as against a temperature of 65° at the surface, showing an increment of 1° per 121 feet of depth. The various efforts to mitigate the heat by vigorous ventilation have been handicapped by the extraordinary character of the development. The longitudinal section, given herewith, looks like a cross-section of a lode; indeed, the terms used in the annual report would readily mislead the casual reader, for we are told that the 'lode' has flattened in 'dip' from 40° at Horizon XVI to 19° at Horizon XXI. We have substituted the word 'orebody' on the section, which shows not the dip of a lode but the pitch of an ore-shoot. The dip of the lode that contains the ore-shoot is indicated by the plan; evidently it is nearly vertical. The best description of the Morro Velho lode is that prepared by the late Orville A. Derby of the Brazilian Geological Survey in 1901. He stated that the lode lies in calcareous schist and follows the almost vertical foliation, whereas the orebody follows a fault-plane inclining eastward at an angle of 45°. He talks of 'lode' and 'dip', and it is from him presumably that the mine officials obtained their incorrect terminology. It would appear that we have here an orebody lenticular in plan and funicular in section. Probably it occupies an acute torsional fold in the schist, where it has undergone such slipping and shearing as to create a channel for the circulation of mineralized waters. The ore is a massive mixture of pyrrhotite, with arsenical and common pyrite. Quartz is a subordinate constituent, as compared with most gold veins. The orebody has become longer and narrower in depth, being 1000 feet long and 12 to 15 feet wide on the lower levels, as compared with the nearly uniform length of 600 feet and the width of 45 feet exposed in the upper workings. Thus the accompanying section shows not a thick lode dipping at a lessening angle but a short and well defined orebody pitching strongly within an almost vertical lode-channel. It is an ore-shoot of a shape so well defined in length and so persistent that it might be called a 'chimney'.

The mine was worked first by means of a large open-cut, which eventually collapsed. Then two vertical shafts, 'C' and 'D', were sunk to 2264 feet, which is the level known as Horizon VIII. That was in 1892. Since then the mine has been developed, as the section shows, by a series of internal shafts, each 1200 feet deep, in step-like succession, the first starting 610 feet east of the 'C' and 'D' shafts, and each of the succeeding ones 1420 feet farther east, connected in turn by a level parallel with the orebody at a safe distance within the country-rock. Between Horizon VIII, 2264 feet below the surface, and Horizon XXII, at a vertical depth of 6426 feet, there are

four vertical shafts and four main levels, making a total connection very nearly two miles long. This, of course, is a most undesirable method of deep mining. It is obvious that the management has not been sufficiently confident of the persistence of the orebody to adopt a courageous and economical plan of development. It is proposed now to sink two shafts, parallel with each other and inclined at an angle similar to that of the orebody. These shafts will be 55 feet apart, centre to centre, and will start at the western, or inner, end of the orebody. The interval between levels will be, as heretofore, 300 feet vertically, which corresponds to 900 feet on an in-

least two other schemes of development. A vertical shaft could have been sunk through the eastern ground, to cut the orebody, say, at 5000 feet. Another plan would have been to start an incline from Horizon VIII, connecting with one of the vertical shafts, 'C' and 'D'. Such an incline could have been sunk at an angle equal to that of the pitch of the ore, which down to that depth had been remarkably regular. Lower down, owing to the flattening of the pitch, the inclined shaft would have passed out of the ore and under it, inviting a change of angle in conformity. It may be that owing to the character of the lode, it might have been advisable to sink the incline

THE MORRO VELHO MINE OF THE ST. JOHN DEL REY MINING COMPANY

cline of 19° . It is intended to use a single-track tramway in the downcast shaft, with a loop arrangement at the point where the ascending and descending cars will pass each other. The upcast shaft from level to level will be used as one continuous shaft if it proves advantageous. From Horizon XXII to Horizon XXVI the length of the inclined shaft will be 3600 feet, but it is estimated that the cost of sinking will not be anything like as great as that of a vertical shaft sunk from the surface. At present the time lost by the men in walking along the levels and in traveling down the shafts is fully one hour per shift. This is a nice problem, and we submit it to our fellow engineers. Obviously it is easy to write last year's almanac, that is, to see the blunder that has been made. When the mine was young, it invited at

outside it, in the wall-rock. That would depend upon the relative hardness and character of the ground within and without the lode. Perhaps, for the sake of ventilation, it would have been desirable to sink an inclined shaft and connect it with a direct vertical opening. As we have suggested, hindsight is easier than foresight; we are disinclined to adopt a tone of patronizing criticism toward such a man as Mr. Chalmers, whom we respect greatly, but it is fair to say that the hand-to-mouth policy of the management might have given way to something better if one or more engineers with large experience in such matters had been called into consultation at least twenty years ago. In any event, the conditions at the St. John del Rey are unusual, if not unique, and they invite discussion.

DISCUSSION

Centrifugal Pumps

The Editor:

Sir—I should like to correct two errors in my article on 'Centrifugal Pumps' in your issue of July 17. The fifteenth line from the bottom of page 86 should read "gauge shows the static and friction heads in the . . .". The word "velocity" should be omitted, as the suction-gauge shows the velocity-head in the suction-pipe and this is the same in the discharge-pipe unless the discharge-pipe is of different diameter. In this case the correction for the difference in velocity-heads is made as indicated at the bottom of the page.

In line 5 on page 87 the words "per second" after 1.5 ft. should be omitted.

ROBERT S. LEWIS.

Palo Alto, September 10.

Dredging in New Zealand

The Editor:

Sir—We note in your issue of August 28 on page 324, an account of an American-made gold-dredge for New Zealand, which is now being built by us. In the second paragraph of the account it mentions that the "dirt is dropped on the conveyor-belt and is carried to the screen". This would rather indicate that it is a freak dredge, as such a method would be impracticable. The material is dumped directly into the screen and there is no conveyor-belt that enters into this part of the dredge.

The last paragraph states that "418,745 cu. yd. has been dug in a period of two years". This figure should have a naught on the right-hand side so that it would read 4,187,450 cubic yards.

We did not furnish these data to you, otherwise it would not contain the errors. If you care to make these corrections, we will be glad to have you do so.

New York, September 10.

A. C. LUDLUM.

A Suggestion

The Editor:

Sir—The 'Mining and Scientific Press' has always taken a lively and progressive interest in the far too common disputes between capital and labor. This letter is written to suggest a solution that is not claimed as original, but that would be recognized as a distinctly mining contribution applicable to all industry.

This solution will not satisfy the professional agitator in the ranks of labor, who does not believe in the sacred and necessary right of private property, and who would abandon American ideals of liberty for Bolshevik ideas

of license. Nor will this solution satisfy the profiteer, who believes that labor should only be paid as a commodity, governed by the law of supply and demand.

Consider a prospector as representing labor. He is grubstaked and provided with tools to work by a capitalist. The profits of the partnership are divided 'fifty-fifty', if the editor will permit me to use that expression. My proposal is simply that wages be very low, just enough to fill the dinner-pail, and that at the end of each year two dividends be declared, stockholders and employees on a 'fifty-fifty' basis. I claim that production would be increased enormously, and that this form of profit-sharing is the real American square deal for both capital and labor.

I can think of a number of objections, but believe none of them are insurmountable. A bare living wage plus the 'fifty-fifty' division of dividends would be a happy ending to our grave industrial troubles.

Seattle, September 7.

HARRY H. TOWNSEND.

[Who is to define the "bare living wage"? Ideas on that point have changed greatly since the common laborer has begun to enjoy, or at least to buy, luxuries.—EDITOR.]

Baking a Gold Ore

The Editor:

Sir—I have read the article on this subject in your issue of July 17, and write to say that while making some cyanidation experiments recently I made observations similar to those of Mr. B. L. Gardiner. The ore was auriferous galena, with some pyrite, in a quartz gangue. About 40% of the gold could be amalgamated; of the remainder the galena carried three times as much as the pyrite. The heads assayed \$105 per ton. When all the ore was crushed to minus 150 mesh with 75% of it passing through a 200-mesh screen the extraction by cyanidation in 96 hours was between 60 and 65%. If, however, the sample used in the experiment was baked so that the normal dove-gray color was changed to a light-brownish tinge, the percentage of extraction rose to 95% and better in a period of 48 hours, with no important increase in the cyanide or lime consumption. The heat was not high enough to roast the ore; in fact, I found that baking for two minutes was as long a period as was necessary. I take it that the heat develops cracks in the ore and permits a readier penetration of each particle by the cyanide solution. I found that however prolonged the agitation, within reasonable limits, the tailing could not be lowered in value to less than \$2 per ton. This insoluble portion of the gold might have been contained as distinct entities

in such of the grains as were unaffected by the heat, but I am inclined to believe that this residual gold is mainly in solid solution in the galena, that is to say, it forms with the galena so intimate a mixture that the solvent action of the cyanide is practically impossible. The baking process is unlikely to be an economic one on low or medium-grade ores containing, as mined, a large amount of moisture. It seems most applicable to high-grade ores. Crushing could be done in water, the slime could be filtered, and the discharge baked prior to cyanidation.

PAUL T. BRUHL.

San Juancito, Honduras, August 24.

Power Resources

The Editor:

Sir—The editorial entitled 'A Grievance', in your issue of September 18, calls attention to what is undoubtedly a just ground of complaint on the part of the mining companies of this State, and one of the unpleasant elements of the situation is the knowledge that comparatively a small part of the water-power available on the Pacific Coast has been developed for industrial use. Referring to the reports of the U. S. Geological Survey, we find that in the New England states, where there is 1,951,000 hp. available, power-plants have been erected with a total nominal capacity of 1,506,000 hp., whereas on the Pacific Coast, out of 25,850,000 hp. available, or 13 times the amount on the Atlantic side, we have utilized but little more horse-power than the Atlantic states. The figures reported show that the New England states have developed 77.2% of the maximum (not minimum) available, whereas the Pacific states have developed only 6.6%. It is generally assumed that one of the important reasons is the great difference between the maximum and minimum flow. The figures given by the U. S. Geological Survey do not warrant any such conclusion, the minimum quantities being 868,000 for the New England states and 1,504,000 for the Pacific states. One of the real reasons is the character of the loading. It seems probable that the peak-loads are much higher here than in the East. It is not practicable, of course, to use storage batteries when the regular load is at the minimum. Mme. Curie and others have shown the enormous amount of energy released by the disintegration of radium. If some other physicist will show how this energy can be utilized and at the same time how radium can be regenerated the power problem would be solved. Power-plants could then always be operated at the point of maximum efficiency, the manufacture of radium acting as a storage battery.

In default of this, why would it not be advisable for the large power companies to construct, through subsidiary or allied companies, large electro-chemical industries at favorable places, industries in which the expense for power is a large proportion of the total, and operate them in times of high water and minimum loading, the product being stored for use, as demanded, throughout the year? As an example, take the production of oxygen.

Companies using oxygen in large quantities for welding purposes, such as the manufacturers of mining-machinery, shipbuilders, and fabricators of structural steel, might, with advantage to themselves, build a plant for the electrolytic dissociation of water, so arranged that it would operate only at certain hours of the day or would automatically be cut into the circuit when the amperage was below a given quantity. In the use of welding and cutting devices the greatest item of the expense for supplies is the freight on the containers, if oxygen or acetylene, and on by-product (lime) if carbide.

The use of powdered coal is developing rapidly and if more combination plants were built, greater advantage could be taken of cheap electrical power. The power companies give special rates to users whose load is uniform, and better ones to companies that can take their power requirements at a time of the day when the regular load is at or near the minimum. If the user should then build his plant so that his requirements would conform to this condition and the excess be taken up by steam-power from powdered coal the greatest economy would be obtained.

This is not all. The U. S. Geological Survey reports that the petroleum resources of the country will be exhausted in twenty years, but what real difference does it make? The coal resources are supposed to be sufficient for two thousand years and it seems probable that pulverized coal will be substituted for fuel-oil in many industries long before the twenty years has expired.

When fuel-oil is \$2.50 per barrel a million British thermal units cost about 38c., and in the case of coal 38c. per million British thermal units would correspond to a price of \$10.60 per ton (about). Gasoline at 30c. per gallon means \$2.25 per million British thermal units. The use of pulverized coal is even more simple than oil, except in oil-engines, and there is no apparent reason why it cannot be adopted for automobiles. Of course for this purpose the use of gasoline is simpler and the small amount required causes difficulty in exact regulation of the charge of a single cylinder, but these difficulties undoubtedly can and will be overcome. Perhaps there will be a reversion to the old steamer-type, but more likely some kind of mixing-chamber will be used in which the coal is kept in suspension in air by violent agitation, the charge being drawn as a mixture of air and coal-dust, or perhaps a small gas-producer will be placed under the hood and the pulverized coal will be supplied by agencies as is gasoline. Of course the ash is a difficulty, but not necessarily an insuperable one, and at any rate the difference between 30 or 40c. and \$2.25 is sufficient to warrant quite an amount of expense in development of some arrangement that will permit the use of these resources. The use of organic substitutes for gasoline on a large scale is not practicable because the world will soon need all the available soil for food supplies. The development by the Government's engineers of the mixed oil and pulverized coal seems a long step in the direction indicated and will probably soon be followed by others.

San Francisco, September 21.

FIG. 1. PNEUMATIC TEST EQUIPMENT. FLOTATION MACHINE, REDUCTION VALVE, FILTERS, AND DRYING-OVEN

Testing Ores for Flotation

By JAMES M. HYDE

The factors involved in the concentration of ores by flotation are so few in number and so readily applied in a small way that it is possible to gain a fairly accurate idea as to the character of the concentrate that may be obtained by flotation, and even the total percentage of recovery that may be made by this process, by means of simple apparatus and small quantities of ore.

It may be the purpose of the testing to determine the character and value per ton of the concentrate that will be yielded if all the metalliferous constituents of the ore are recovered as a single product; to determine the percentage of recovery of the metals that may be won by the concentration; or to recover one or more of the metalliferous constituents of the ore in a concentrate separate from the others. This last—selective flotation—is capable of a degree of development requiring very careful selection of the flotative and modifying agents to be used, and will not be discussed at this time.

The recovery of the metalliferous constituents of the ore in a single concentrate is not a very difficult task if the ore is amenable to treatment by flotation, and any test by which the operator wishes to determine the general characteristics of the concentrate to be produced or the total recovery possible by floating all the floatable contents of the ore together may be made with some kind of standard mixture of oils and tars that will be generally applicable. Various oil-mixtures have been used for this purpose by different operators. I have found a mixture of three parts Pensacola Tar & Turpentine Co.'s No. 400 pine-creosote or its equivalent, three parts of carbolic

creosote, and one part of crude coal-tar or pitch; makes a satisfactory combination for general testing purposes. For pyrite alone, the No. 400 pine-creosote is usually satisfactory. Others have found crude pine-oil plus 10 to 25% of crude coal-tar satisfactory.

The simplest apparatus for testing ores by flotation is a good-sized clear-glass bottle. A quart-bottle will do very well for 100-gm. samples of ore. An ordinary acid-bottle, such as those in which acids are sold, may be used on samples up to 500 grammes. To carry out the test, the bottle should be washed clean and half-filled with the crushed ore and water in the proportion of one part by weight of ore to from two and a half to four parts of water; using a quart bottle, a pint of water and 200 gm. of ore may be used and the test may be started with five or six drops of oil; using an acid-bottle, half a bottle of water and 500 gm. of ore make a good charge, and from six to twelve drops of oil are used at the start. After the oil is added to the pulp the bottle should be shaken violently with an up-and-down or horizontal movement and brought to a stop in a vertical position, using care to leave pulp as free from rotary motion as possible. If the ore is especially adapted to flotation and the correct amount and kind of oil have been used, a considerable portion of the metalliferous constituents should rise to the top of the pulp as a froth. After the slime has settled this froth may be removed by carefully raising the water-level in the bottle by adding water through a funnel, the lower end of which is below the water-level, or by pouring water carefully down the neck of the bottle.

The sides of the interior of the bottle should be wetted first by pouring clear water slowly into the neck of the bottle. After the froth has overflowed completely the bottle may be permitted to stand until the pulp is settled sufficiently so that the excess water may be siphoned off,

oil-mixture to use in a mill or in more elaborate tests. It is also helpful in the field or in the mill, for arriving quickly at a qualitative test which will indicate the nature of the concentrate that may be obtained from any particular ore.

FIG. 2. DETAILS OF MACHINE FOR AGITATION TEST

FIG. 3. DETAILS OF MACHINE FOR PNEUMATIC FLOTATION

FIG. 7. PNEUMATIC MACHINE FOR CONTINUOUS TESTING

and the operation may be repeated with or without the addition of further amounts of oil. This operation may be repeated until it yields no more froth. The bottle-test may be repeated upon an ore, using one oil after another, until an oil or mixture is obtained that gives the best results. This test is helpful in selecting the proper

As a qualitative test it may be of a great value in the hands of the mill-foreman or shift-boss in testing the tailings from flotation machines or from vanners and tables, and in testing the overflow from de-watering devices, to see how much fine sulphide they contain. I have found this test very useful around plants. No equipment

is needed other than a clear-glass quart-bottle and a bottle of the oil or oil-mixture that has been found suitable for the ore, this bottle being equipped with a good drop-stopper. The type of bottle used for Welch's grape-juice, because of its shape and size, is particularly useful for collecting samples to be tested and for overflowing the concentrate most completely and quickly.

The bottle-test may be made to yield quick quantitative results of fairly reliable kind if it is manipulated skillfully, repeated agitation being used until no further concentrate is produced. A simple method of expediting the work is to take an india-rubber sack or 'balloon', such as is made for the whistles that delight children. If one of these, attached to the end of a glass tube, is introduced

as before. A sufficient amount of sulphuric acid may now be added to start the generation of carbon di-oxide in the pulp, and the bottle may be filled with water so that the froth as it rises will overflow into the pan in which the bottle is set. By keeping the pulp stirred with a long rod or tube the sulphides may be completely removed by flotation; if the proper amount of the oil best adapted to the work is used. This manipulation requires some skill and is not recommended for general use; but, like the other bottle-test, it may be advantageous if no other equipment is at hand than that with which the bottle-test can be made. If the pulp is heated, or if the amount of sulphuric acid added is too large, the gas may be generated so rapidly as to expel the pulp from the

FIG. 4. AGITATION MACHINE AT WORK

into the bottle after the agitation has taken place, water may be introduced into the sack through the tube and the water-level raised so that the concentrate overflows without the pulp being diluted. The rubber sack may then be emptied by siphoning and the operation may be repeated with the minimum loss of time. If a rubber bag is not available, a sheep's or pig's bladder might serve as a satisfactory substitute.

On certain ores a modification of the bottle-test may be carried out effectively where the desired result is not a process to be used in practice but to get a quick idea of what kind of concentrate the metalliferous constituents of the ore will yield when separated from the gangue. The manipulation is as follows:

To the pulp in the bottle may be added from 1 to 10% of limestone, ground sufficiently to pass an 80-mesh screen. The oiling and the agitation may be carried on

APPARATUS FOR PNEUMATIC FLOTATION. THE AUTHOR AT WORK

bottle. For this reason, the acid should be added carefully, and with stirring, so that the generation of gas will be kept within bounds. The acid may be added before the agitation takes place if sufficient care be used, in which case the test may be completed more quickly than by any other means, as it may be possible to raise the concentrate completely at one time; but this is not recommended generally because the generation of gas may be so rapid as to throw the acid pulp out of the bottle onto the operator.

In carrying out any test in which acid is used in the presence of a carbonate, the mouth of the bottle should always be pointed away from the operator.

For making flotation tests by mechanical means, a simple apparatus will give reliable results with either the agitation or the pneumatic process. Many types of appa-

ratus have been used and described in the technical press, but the two described herein are so simple and have yielded such satisfactory results that I have come to rely upon them exclusively in my own work.

The machine for carrying out the froth-agitation flotation process consists of a rectangular box in which agitation takes place, and a pointed box in which the froth separates from the rest of the pulp. By reference to Fig. 2 the details of this machine will be apparent. The pulp is kept in continuous agitation and continuous circulation from the agitation chamber through an opening (1) into the separation chamber or spitzkasten from which it returns to the agitation chamber through the opening marked (2). The impeller has blades set at an angle of 45° from the vertical, and is placed about half-way between openings (1) and (2). The impeller is adjustable as to height and may be raised so high that the agitation chamber is completely open for inspection or cleaning. Ordinarily the impeller is adjusted until the best position is found and then left at that position.

The method of procedure in making a test with this machine is to close the opening (1) with a cork, introduce water up to a point just below this opening, and start the impeller. The dry ore is now added and mixed thoroughly with the water, water being added until the level in the separation chamber is about half an inch below the height of the overflow lip. The oil or oily mixture to be tested is added in the proper amount. Where a 500-gm. charge is used the initial addition of oil need not be more than from six to ten drops, unless previous testing has shown that as much as ten or fifteen drops are needed. The oil is added most conveniently by means of a 1-cc. pipette graduated to hundredths. After a sufficient mixing of the oil and pulp has taken place, which should be in about half a minute, the cork may be removed from the opening and the pulp allowed to circulate; from time to time, the froth floating upon the surface of the water in the separation chamber may be removed by a paddle and further additions of oil may be made in small amounts so long as they continue to produce more froth. After the last concentrate is removed, the tailing may be discharged through the opening indicated by (3). The machine is washed out conveniently by means of a stream of water from a hydrant or other source, carried through a rubber tube and a piece of glass tube 13 to 14 inches long, drawn to a tip at the bottom, and the tip inclined at an angle to the body of the glass tube, thus permitting a jet to be applied to the floor of the agitation chamber in such a way as to wash the sand to the discharge opening with the use of the minimum amount of water. After the machine has been cleaned thoroughly the concentrate may, if desirable, be returned to the machine and re-floated in order to raise its grade, the tailing from this operation forming a middling product, which normally would go back into the tube-mill or other fine grinder, to be re-ground and returned to the flotation machine with the regular feed.

This machine is a slight modification of others that have been described previously, its chief individual merit

being that it is driven from overhead, the height of the impeller is adjustable, and the settling-chamber is adequate, and is so arranged that the pulp circulates thoroughly without the use of any piping. The impeller in a machine of this type should be driven at a speed of 800 to 1600 revolutions; 1200 is usually about right.

The pneumatic machine shown in Fig. 3 is useful and can be constructed cheaply. It consists essentially of a wooden base into which is sunk a recess, to be used as an air-pocket into which air is introduced from some simple blower through a gas-cock and short nipple. Over the air-pocket in this base is placed, first, a square rubber gasket, then two thicknesses of 10-oz. duck or its equivalent, then a square of ordinary metallic mosquito netting, and a second rubber gasket, above which is mounted a square metallic cylinder open at each end (having a flange at the bottom as indicated and a basin at the top to receive the concentrate as it overflows), this basin being equipped with a spout by which the concentrate as it overflows is directed into the collecting-basin. That portion of the edge of the canvas which goes under the flange may be saturated with asphalt, care being taken that it does not permeate the portion of the canvas going under the inner portion of the cylinder. The cylinder is attached to the wooden base by a number of screws, and is screwed down in place so tightly that no air or water will escape through the edge of the canvas. The flange, which is made by bending up pieces of the sides, should be reinforced by a square with the centre cut out.

A test is performed in this apparatus as follows:

Five hundred grammes of ore is mixed with 1250 to 1500 cc. of water in an acid-bottle, which is shaken to wet the ore and make a homogeneous pulp. To this is then added from 6 to 15 drops of the oil or oil mixture to be used in the test. The pulp is shaken vigorously until the oil is well mixed with the whole of the charge, as previously described in the bottle test. The oiled pulp is now poured into the cylinder, the air is turned on and carefully regulated by the gas-cock so that the overflow of the concentrate will take place gently. This froth is overflowed until all of the concentrate the sample will yield has been produced. The tailing may be removed from the machine by tipping it up on the end of the base away from the air-intake while the air is still turned on, and washing out the contents with a jet of water. The concentrate may be returned to the machine and re-floated as in the test with the agitation apparatus.

The pneumatic machine is dependent upon compressed air from some source. A small mechanical blower, such as the Crowell blower shown in Fig. 6, is useful for this purpose. Such a blower should be equipped with a pop-valve, which may be set for any desired pressure by adding or removing weights. Fig. 1, 4, and 5 show the machines described, as installed in a temporary laboratory in the Bureau of Mines experiment station at the University of California while war mineral-investigations were being conducted.

In preparing for flotation tests, a representative sample should be carefully crushed to such a size that even the coarsest piece of sulphide mineral will float readily.

In some ores pyrite is of little or no value, and it is often desirable to float other sulphides without floating the pyrite. Ordinarily, pyrite is tougher than the other sulphides, and it may be possible to determine a degree of crushing that will leave at least a portion of the pyrite too coarse to float, while practically all of the chalcopyrite or other sulphide that it is desired to save may be fine enough for successful flotation. If it is desirable to leave part of the pyrite unfloat, a test may be made upon ore crushed so that it will all pass through a 30 to 50-mesh screen. Ordinarily, where it is desirable to float all the sulphide constituents of an ore, the whole sample

under the head of pine-creosotes and pine-tars; the creosotes and tars produced in the destructive distillation of hardwoods; the neutral and acid creosotes, and refined and crude tars produced in the destructive distillation of coal; and certain crude oils and petroleum distillation products. Qualitative tests may often be made with salad-oil, if nothing better is at hand. Small amounts of pine-creosotes and tars, hardwood-creosotes and tars, coal-creosotes and tars, may at a pinch be made by distilling pitch-pine, oak, maple, alder, etc., or coal-tar, in some simple retort.

The simple mechanical apparatus described herein will

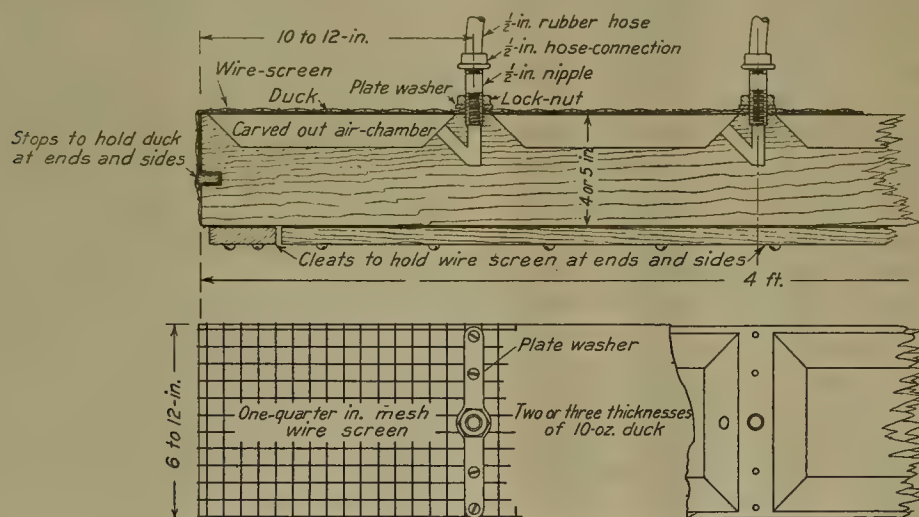

FIG. 8. DETAILS OF AIR-CELL CONSTRUCTION FOR PNEUMATIC TESTING

should be crushed so that it will pass through a 60-mesh screen. Even 100-mesh or finer gives the best results in most cases, especially for the bottle-tests.

In testing an ore for the purpose of working out the

FIG. 6. THE CROWELL BLOWER

details of milling practice, the tests should be made upon samples crushed to different degrees of fineness in order to determine how fine it is necessary to crush to get the maximum recovery, and whether or not a finer degree of crushing is necessary in order to get the highest grade of concentrate possible.

The usual oils or oil mixtures used in flotation work include turpentine, crude or refined; steam-distilled pine-oil, and the whole range of products recovered by the destructive distillation of pine-wood, falling generally

give satisfactory and reliable tests, but much of importance can be learned by the bottle-tests, and they may be constantly used to advantage around an operating mill.

The agitation and the pneumatic machines described herein are entirely adequate for making elaborate studies of flotation problems, changing all factors, such as kind and amount of oil, dilution of pulp, fineness of ore, the use of additional reagents, such as lime, ferrous sulphate, copper sulphate, sodium hydroxide, sodium sulphide, and sodium silicate. Where ore is to be ground dry and many tests are to be made, a quantity of the ore should be mixed thoroughly after grinding and screening, and portions of the pulp to be tested should be weighed out into a number of paper sacks to facilitate rapid work. Some ores do not float readily if they have been dried; so, in checking mill-work, the drying of ores and the grinding of them dry should be avoided.

Large Buechner filters, with filter-pumps attached, may be used where many samples are being handled. Where few samples are being handled and assays do not have to be made promptly a wick filter may be used satisfactorily. A single paper towel folded to about an inch wide and flattened with the end held by a wire paper-fastener may be wetted and one end put in the pan of concentrate, the other end being folded over the edge of the pan and brought down below the bottom of the pan.

Capillarity will remove the water at a surprising rate. With one paper towel I have taken off over 800 cc. of water in 24 hours. If the pan is set on the edge of a sink, the water may be allowed to go to waste as it is removed or it can be caught in a pan. When the sample is air-dry the concentrate on the wick filter may be brushed off. I have found this simple device very useful in removing water from samples of mill-pulp containing slime. Such a sample may be decanted after a reasonable length of time if a pinch of alum is added to it when it is collected. After all the water that can be safely removed is poured off, a further amount may be taken off with a wick filter and the pulp brought to a thick consistence ready to go into a steam-dryer or to be used for flotation tests. A large lamp-wick or a piece of cotton cloth rolled into a wick works well. The paper towel is particularly effective.

A cheaply constructed continuous machine of the pneumatic type can be constructed with a tank of wood or galvanized iron, the air-cells being carved out of a straight grained piece of redwood or pine timber. I have constructed such a machine according to the measurements shown in Fig 7 and 8 and have found it to be very useful in testing under mill conditions. The measurements given may be varied as desired. A machine 4 ft. long and 6 in. wide with two square feet of canvas surface was built some years ago for a total cost of less than \$50.

This type of flotation machine was described in the 'Mining and Scientific Press' of August 5, 1916, and the following description is quoted with modifications from that article. See Fig. 7 and 8.

The body of the machine is a rectangular tank with a sloping bottom or false bottom, and overflow sides. One overflow side will do for testing. Pulp from the launder (1) enters the feed-chamber (2) and flows into the flotation-chamber, where it passes over the wooden air-cells (4), through the upper canvas surface of which compressed air is being forced. The air is supplied through the hose (5) from the header-pipe (6). Each air-cell is regulated independently by a valve (7). The air rising through the previously oiled pulp builds up a bed of mineral-bearing froth above the water-level; this froth flows continuously over the lip (8) and is carried away by the launder (9). The bed of fragile froth, which readily breaks down unless air is constantly bubbling up beneath it, is prevented from flowing over the tailing-discharge, where no air is rising, by a partition (10) that divides a dead-water space (11) from the frothing-chamber. The bulk of the tailing is discharged through the valve (12). The deflector (13) guides any bubbles carried toward the tailing-valve by the flow of the pulp back into the frothing-chamber. The deflector (14) causes a counter-current of froth to flow toward the feed-end of the machine. Slime-tailing flows through the opening (15) and the swing-pipe (16) and through the hose (17) and joins the sand-tailing in the main tailing-launder (18). The swing-pipe (16) may be fastened at any desired height by engaging the proper link of the chain (20) over the nail (21). When the valve (12) is

set so that the valve does not permit quite all the tailing to flow through it, the position of the swing-pipe fixes the height of the water-level, which will not vary until the pipe is re-set.

The details of this machine are covered by my patent No. 1,296,190, but anyone who desires to build test-machines of this type for his own use has my permission to do so.

SOME kinds of dust are much more dangerous than others, a notable example being the difference between the effects of coal dust and silica particles. The silica particles, when they enter the lungs, set up a fibrosis, or fibrous condition of the tissues, which lowers the resistance to tuberculosis; hence it is that men in metal mines are liable to contract the disease. But coal miners, who live in about as dusty an environment as could be imagined, seem to thrive on the air that they breathe. Formerly it was explained that the minute particles of silica or similar substances were hard and sharp, and therefore more dangerous. But the coal dust is also often hard and sharp. When silica dust is mixed with coal or clay dust it becomes relatively harmless. Medical men, seeking an explanation for this, have found that there is a difference in the manner in which the lungs rid themselves of dusts of different kinds. Silica dusts are retained by the lungs, while the coal dusts and soot seem to have some stimulating effect on the lung cells, and are promptly gotten rid of. In other words, when coal dust is breathed, it is coughed out again or otherwise ejected through the nasal or mouth passages; while silica dust remains in the lungs and tends to render them less resistant to infection by tubercle bacilli.

As a matter of fact, coal dust appears even to have a somewhat beneficial effect; coal miners as a class have a low tuberculosis rate. It is not known whether this 'good dust' has some peculiar antiseptic property, or whether it causes a biological reaction tending to aid him who breathes it in his resistance against tuberculosis. The practical application of these discoveries comes in the fact that it now is suggested that in order to avoid the bad effects of quartz dusts, the attempt be made—not to get rid of the dust, but simply to mix with it a neutralizing dust of the coal or soot nature. Probably it will be possible, by adding coal to the dust that cannot be disposed of otherwise, to render it harmless; and just as stonedusting is used in coal mines to prevent coal-dust explosions, so coal-dusting will be used in quartz mines to prevent miners' phthisis.—League of Red Cross Societies.

RECENT experience of tale producers confirms the fact that the fibrous variety of tale, contrary to popular belief, is not always most desired by paint manufacturers. It is true that in certain types of paint fibrous tale is an advantage, but in other types it has the disadvantage of being too bulky for its weight. 'Heavy' granular tales are often specified by paint manufacturers as distinguished from 'light' fibrous tales. Practically all tales are fire-resistant and it seems probable that many of the tales on the market today could be used in paint.

Some Principles of Finance

By ROBERT S. LEWIS

INTRODUCTION. All sound finance should be conducted according to certain principles that are clearly defined, and disaster is sure to follow, sooner or later, any departure from these principles. The recent example of 'Ponzi finance', with his reported maximum assets of \$4,000,000 and minimum liabilities of \$7,000,000 illustrates the truth of the saying that a fool is born every minute. Ponzi's bait was the promise to pay something like 50% return in 45 days through an unexplained use of foreign exchange-rates. Just why the Government officials should have let this fleecing of the public continue for six months or more before taking action is yet to be learned.

A milder form of get-rich-quick scheme has been tried by some Eastern banks which have charged 20% interest or more for short-time loans. An interesting comment on such business methods was made by J. S. Williams, Comptroller of the Currency, who states in a report of August 10 that these high rates "have been one of the potential causes, rather than the result, of the unsettling of values in our securities market, and of the burdensome rates which our railroads and industrial corporations and other concerns and individuals of the highest credit have been requested to pay for new capital essentially needed for the country's development and well-being. . . . Able and thinking business men know that exorbitant interest-rates mean destruction in the end, to the detriment of all, and that stability and permanent prosperity can be assured only by fair and reasonable methods of the financial power."

The hope of getting rich all at once, of gambling and expecting always to win and let others lose, and, in some cases, the demanding of more interest than can be properly earned, have been potent factors in causing many failures, which have created in the minds of the general public the impression that mining is a gamble and not a business, and that, therefore, the recognized rules of finance cannot be applied in mining undertakings.

Intelligent investing in mining enterprises requires a knowledge of business principles that many investors do not possess and a careful investigation that very few seem willing to make. Just why a business man who would carefully investigate a new proposal in his own line of business will shut his eyes and blindly throw his money to the unscrupulous promoter of a flamboyant mining advertisement is a question that psychologists might find it interesting to discuss.

CAPITALIZATION. The methods of capitalizing business enterprises may be divided into four classes. This is only a rough grouping, and enterprises will be found that will occupy intermediate positions.

(1) Capitalization not based on value; its amount is consequently a matter of little importance. The nature

of the enterprise is such that a determination of its value is impossible. An invention in its early stages is a good example. The inventor estimates that a certain sum will be needed to develop his idea and he tries to raise this amount. The invention may be successful and may prove highly profitable, or it may turn out to be of no value and not even patentable. The inventor may give a part interest for a lump sum of money. The capitalization merely serves to apportion the holding of the interested parties and is temporary in its nature. Its chief advantage lies in the fact that large incorporation expenses are avoided until some definite value has been demonstrated. Temporary organizations, when large undertakings are to be incorporated, are often capitalized in this way. The United States Steel Corporation was first organized with a capital of \$3000. This temporary company controlled all options, contracts, and properties for about six weeks. Then the main company was formed and the capital was raised to over a billion dollars.

Close corporations, in which the capital stock is held by a few persons, are frequently capitalized without regard to value. One company doing a business of over \$12,000 per annum was capitalized for \$6000. Each of the three stockholders subscribed for \$2000. The United Verde Copper Company may be considered a close corporation, as it has less than 20 stockholders. This company is capitalized for \$3,000,000, and up to October 1917 had paid over \$44,000,000 in dividends.

(2) Capitalization based upon present value. The capitalization of a new enterprise, well within ordinary lines of business, is a comparatively easy matter. A man may buy a lot, build a store on it, and begin business. The cash or other property put into the business constitutes the entire value of the enterprise and measures its capitalization. If a capable manager can be secured only by the offer of some stock in addition to his salary, this stock must be added to the capitalization. In the case of a corporation formed to take over an existing business, the purchase price plus a suitable working capital and a necessary reserve make up the capitalization. Promoters often take a business at one price and sell it at another, the promoter's profit being included in the new capitalization. If a promoter's share is not excessive, such a method is legitimate.

What is known as 'goodwill' is a factor that enters into the capitalization of going concerns. Goodwill may be defined as the profit-producing power of an established business in addition to interest and replacement returns on the investment. It is intangible, but is an asset of the business and should be included in any scheme of capitalization unless it is of such a nature that it will not remain with the business after a change of ownership. One

method of valuing goodwill is as follows: The net profits are capitalized at a selected rate. If 10% is determined upon, a business returning a profit of \$6000 per annum would be capitalized at \$60,000. All property values are deducted from this and the remainder is the capitalized value of the goodwill. Thus, if \$40,000 constitutes the value of the property the value of the goodwill is \$60,000 less \$40,000, or \$20,000.

In large corporations the issue of common stock is frequently based on goodwill. Preferred stock is issued to the full amount of the material assets. The dividend to be paid on this stock is deducted from the total net earnings, and the remainder, representing the earnings of goodwill, is used as the basis of the issue of common stock. For example, let the net earnings of a concern to be capitalized be \$2,000,000 per annum. The value of the property is \$15,000,000. Then preferred stock is issued to this amount. If 7% is paid on the stock, the amount of the interest, or \$1,050,000, is deducted from the annual income of \$2,000,000, leaving \$950,000 as the basis for the issue of common stock. Assuming that 5% will be paid on this stock the issue would then be \$950,000 at 5%, or \$19,000,000. The total capitalization would be the sum of the stock-issues, or \$34,000,000.

(3) Capitalization based upon future profits. In this case the profits are estimated; they are not an accomplished fact. If kept within reasonable bounds, this capitalization of profit probabilities is perfectly legitimate. The stock of a business that pays 7% dividends may sell at par or \$100 per share, but a similar stock paying 14% will not necessarily sell for \$200. It is more likely to be priced at from \$170 to \$180 per share. If the owners are considering a future sale of stock, and believe that the increase in earnings will amount to 7%, it would be legitimate for them to increase the capitalization 100%.

When inventions are capitalized it is customary to anticipate their earning power. An accurate estimate, of course, is impossible. The usual procedure is to estimate the earnings as accurately as is possible and then discount this figure by a safe margin, using the result as the basis for capitalization. This capitalization must be large enough to provide for all operating expenses, for any required sinking-funds, for stock-reserves held to meet future emergencies, and for such additional stock for the inventor as will fairly represent the value of the invention.

In enterprises that include a franchise among the assets, it is as legitimate to capitalize the franchise as any other property of the corporation. Assume that a group of bankers secures a 25-year franchise to build and operate a water-supply system. An engineering estimate of the plant is \$750,000. This covers both pumping-station and the system of distribution. For safety the amount is taken at \$800,000. A study of the problem indicates that 12% should be realized on this investment. The project would therefore pay \$96,000 per annum. The bankers are entitled to 6% on their money, or \$48,000. If a sinking-fund of \$24,000 is set aside to amortize capital and to meet emergencies, the remain-

ing \$24,000 of yearly income can be attributed to the franchise. At 6%, this makes the franchise worth \$400,000; consequently the enterprise would be capitalized for \$800,000 + \$400,000, or \$1,200,000. This is not over-capitalization, since the amount is justified by the earnings. Mining companies are nearly always capitalized on the bases of future profit.

(4) Capitalization when the value of the enterprise can only be determined by development. In these cases the capitalization is fixed by more or less intelligent guesses. New processes, inventions outside the realm of experience, and mining prospects would come under this head. The actual value of the undertaking cannot be determined, so the promoters issue and sell stock for what they can get for it. It is not wrong to offer stock as a gamble provided conditions are truthfully represented. Misrepresentation of conditions constitutes the fraud in this case. A few men buy an acre of land in or near a well-known oil-field. The acre is divided into sixteenths. At the point where four tracts meet a well is started. Four companies may be formed, one for each tract, and stock is sold to the public on the strength of the advertisement that the X. Y. Z. company is sinking a well in a proved oil-field. The promoters reap a rich harvest and the public pays for it. If no oil is found, the performance may be repeated at some other point on the acre. The newspapers are full of advertisements of this kind. It is a safe rule never to buy because of newspaper advertisements. The game is always one of heads I win, tails you lose.

OVER-CAPITALIZATION. Capitalization that is in excess of the proper needs of the enterprise has caused the failure of many a meritorious promotion. The earnings were never adequate to pay dividends on the huge capital involved. In some cases of improper management dividends were paid that were never earned, the money being taken from paid-in capital that had been held in reserve. This point will be discussed more fully under the head of dividends.

Over-capitalization is generally due to one of four causes: First, fraudulent intent. Owing to the great risk of capitalizing nothing at all, some tangible property must be used as the basis of the promotion. Generally, the property selected is in such a remote region that investigation is either difficult or impossible. In other cases, the victims are swindled through property that could easily be investigated, but such an investigation is seldom made. The Royal Diamond Company operated on Wall Street and reaped a rich harvest until the authorities interfered. The company claimed to own valuable diamond mines in South Africa. Stock was sold for alleged development work. The board of directors, composed of titled Englishmen, banking references in different parts of the world, maps, and reports were pure fabrications. Nothing existed except the office furniture, the swindlers, and their victims.

A second cause of over-capitalization is the method of promotion. Showy offices, the payment of large commissions and salaries, and other concomitants of flashy promotion, leave little of the large capital subscribed to

be used in the legitimate development of the enterprise. Some years ago the promotion of a certain copper company was undertaken in this way. A dinner at \$5 per plate was given by company officials to brokers and friends, expensive advertising literature was published, and development was started on a large scale. Examination of the property by competent engineers proved the existence of veins that contained good ore, but the faulting of the orebody had been extensive, thereby making the maintenance of a uniform daily output of ore a difficult matter. The enterprise dragged along for years and not a cent in dividends was ever paid. No fraud was intended, and the property had merit, but only the most competent management could make such a mine pay, and the margin of profit would be small in any case. Certainly, dividends could never be paid on the excessive capitalization. Spendthrift methods of promotion killed this mining venture.

A third and frequent cause of excessive capitalization is over-sanguine estimates of value. The inventor of a meritorious device receives a large sum for his invention. Unusually large royalties are also paid him, and he may be made general manager of the factory at a handsome salary. In this way money put into the enterprise is used up and business comes to a standstill until additional subscriptions can be obtained. Under this head would be included the cases in which the owner asks a fair price for his property but tells the promoter that he can have all the profit he can make above this price. The promoter then tries to secure such a large profit that the load imposed on the enterprise is beyond the possibility of any reasonable profit or dividend-paying possibility.

A fourth cause of over-capitalization is the avarice of owners. This is similar to the preceding case. A price beyond all reason is asked for the property, and there is no possibility that any profit can be made on such a heavy investment. Although not a cause of over-capitalization, the avarice of owners of mining prospects is one of the chief reasons why more prospects are not developed. The owners ask such unreasonable prices that mining and development companies that have ample capital to develop such possibilities are not willing to make the investment.

AMOUNT OF CAPITAL. The total capital required for an enterprise may be divided into two kinds; fixed capital, or that invested in plant, real estate, and equipment; and working capital in the form of raw materials, stocks of partly finished goods, finished products not sold, accounts receivable, salable securities, and cash. Fixed capital is in forms that cannot be disposed of without breaking up the business. The proportion of working capital, in terms of total capital, that is required in some lines of business is much greater than in other lines. Telephone companies have large investments of fixed capital, but after the equipment is in place, operating expenses are light and can be paid by the monthly receipts; consequently, little working capital is required. On the other hand, a retail business in a rented store would have nearly all of its capital in the form of goods or working capital. Ample working capital is a necessity in any

business. A concern manufacturing a patented device may have a large investment in plant and equipment. Sufficient working capital may have been provided, but later developments show that the device itself or the method of manufacture must be changed and, therefore, the fixed capital is wasted. A better procedure would have been to have some company manufacture the device under contract for a year or two and to devote the available capital to building up a strong selling organization until the best method of manufacture had been found. Then the additional capital needed for building the plant could easily be obtained.

For mining companies, the necessary investment in buildings and equipment can be quite satisfactorily determined. The working capital must at least be sufficient to meet the expense of development work, supplies, and payroll, until the product can be marketed. If the product of the mine can be sold within a short time, less working capital is needed than if the product must be carried for months before it can be marketed. Gold bullion may be sold at any time, but stocks of copper, lead, or zinc may have to be held for a long period of time in order to secure favorable market conditions. In the case of a company using a well-tried process of reduction, such as cyaniding, gravity concentration, or smelting, little is required beyond the fixed capital for the plant and a reasonable allowance for working capital. The method employed and the machinery used have been proved by experience and can be depended upon, but for new and untried processes ample working capital must be provided for making the changes that will certainly be required either in the process or in the plant and to cover breakdowns that will inevitably occur. A good example of the need for sufficient working capital is found in the case of a plant in which a leaching process was used for treating copper ore. The design of the plant was original with the metallurgist in charge. Nearly all the machinery was of special design and had to be made to order. This meant a long delay in getting the machinery on the ground. As soon as the plant was put in operation, trouble developed at many points; much of the machinery had to be changed; some was found to be superfluous and some had to be re-designed. This necessitated another long delay before operations could be resumed. The plant has cost several times the original estimate. Even in a plant using a well-tried process of reduction, there is a period of 'tuning up', or working the plant into smooth operation, that takes more time than was estimated and requires the expenditure of considerable money. More meritorious mining enterprises have failed through lack of adequate working capital than perhaps for any other reason.

A certain prospect has a promising appearance and a group of men organize a company to develop it. An estimate is made of the cost of plant and development. This capital is subscribed and work is started. The orebody had not been fully prospected, and the development work shows that mining will be more difficult than expected because of extensive faulting of the orebody. An expensive pumping-plant may be required to handle the

large flow of water developed on the lower levels. Damage to plant through fire or other accident postpones the period of production and calls for more capital to repair the injury. Several months of operation may be required before full production is attained. As a result, the owners have to pay assessments or become discouraged, and sell out at a loss. The property makes a successful mine in the end, but only when sufficient capital has been put into it.

DIVIDENDS. These are declared out of net profits by the board of directors. Once a dividend has been declared it becomes an obligation of the company and must be paid. Stockholders have no voice in determining the amount or time of dividends. The regular payment of dividends is desirable, and is considered an important principle of modern business finance. Most stockholders know little or nothing about the inner working of their company. They have bought stock as an investment and a regular income is desired. For this reason well-managed companies try to maintain uniform dividends. Profits vary from year to year and regular dividends can be maintained only by placing the rate at a conservative minimum. Whenever profits are great enough to permit of increasing the dividend, an extra dividend is usually declared. This dividend is often sent as a separate check, to indicate that it is an addition to the regular dividend and may not be paid again.

It is a serious mistake for a new company to declare dividends too soon. Stockholders frequently become impatient for dividends. They have been known to bring such pressure to bear on a board of directors as to force the board to declare a dividend sooner than their best judgment dictated. It takes time to develop a mine to a dividend-paying basis, and no intelligent investor should agree to a distribution of dividends until it is perfectly safe for the company to pay them. This premature payment of dividends has been the cause of much financial embarrassment. The payment of dividends should depend not only upon the profits earned but upon the financial position of the company as well. Working capital is reduced by the payment of dividends, and until a company is upon a well-established financial footing any impairment of working capital is dangerous. A satisfactory cash balance should be built up and this cannot be done if profits are paid out as dividends the moment they are earned. Fires, the caving of a part of the mine, change in the grade of ore mined, strikes, and other contingencies may arise. If no adequate cash-reserve is maintained an assessment must be levied or money must be borrowed to meet the emergency.

In some instances dividends have been paid from borrowed money. Though this is most always done for speculative purposes to keep up the price of stock, such a method is legal and may be justifiable for a company that faces wide seasonal fluctuations in earnings, but the wisdom of such a policy is open to question. Fraudulent payment of dividends out of capital has been known, but the directors are legally liable for such dividends. The payment of unearned dividends is due to ignorance on the part of the directors, or to their belief in large future

profits, or to their desire to give the company a higher standing either on the stock market or with creditors than the earnings warrant.

Dividends from mining companies should be paid according to these business principles, but the investor in mining stocks should recognize the fact that his dividends differ from those derived from other industrial companies. A mine is a wasting asset. The orebody is not unlimited in size and every ton mined lessens the ore-reserve. When all the ore has been taken out of that particular mine it has reached the end of its life. Dividends from a manufacturing concern may be considered wholly as income, but dividends from mining companies should be considered as part income and part return of capital. If a mine has a life of, say, 15 years, enough of the dividend should be put into a sinking-fund so that it would accumulate to a sum equal to the purchase price of the shares at the end of the life of the mine. The remainder may be used as income. Should the whole dividend be spent as income, the investor would lose the purchase price of the shares, as they would have no value when the mine had been worked out.

In regard to the dividend-rate that should be expected from the investments in mines, the principle to follow is that the rate should be proportional to the risk involved. The greater the risk, the higher should be the rate. Government bonds or money in the savings bank may receive as low a rate as 3 or 4%, because of the safety of its position. A well-established manufacturing concern may pay 5 or 6%. Here, the element of risk is greater. A panic or some unforeseen contingency may cause a failure, but the danger is remote. At best a mining investment has a large element of risk attached to it and therefore the return should be proportionately great. For a proved mine that is well managed and has large ore-reserves, the rate may be comparatively low, say, 8 to 10%. Many engineers state that 10% should be the very least expected from a mine. Since this is not all income, as part must be used to replace the investment, 12 to 15% would compare favorably with, say, 7 to 10% in manufacturing or other industrial enterprises. For a mine in a foreign country the rate should be much higher. As high as 50% has been asked on investments in mines in foreign countries, where the mines were not fully developed though they were of great promise.

FORM OF CAPITALIZATION. When the amount of capital to be raised has been determined upon, it is necessary to select the form in which it shall be raised. The common forms are stocks and bonds. Bonds are really notes or promises to pay a certain sum at a specified date. They are usually secured both as to principal and interest by a deed of trust or a mortgage on real or personal property. Because of this safeguarding of the investment the interest-rate on bonds is comparatively low; 5 or 6% is a common rate for good bonds, though at the present time the rate may be 1% higher. In exceptional cases, where money must be raised on short notice, desirable bonds may be placed on the market at a rate as high as 8%.

To the promoter or organizer of an enterprise a bond

is the best method of raising capital. The interest-rate on the money borrowed is low, and large earnings can be used to pay dividends on the stock of which the promoter holds a large block. The bond-buyer surrenders all chances of a high return on his investment for the great safety involved. If necessary, he can foreclose and take over the property to his own advantage. If the stockholder receives no dividends and his stock drops to almost nothing in value, he is helpless unless he can prove that the management has been dishonest. However, certain enterprises do not make a good basis for bond-issues until they are well established, and even then bonds could be issued for only a moderate percentage of the value of the property. A mining company falls under this head. The usual method of raising capital for a mining company is by an issue of stock. The speculative appeal of such an issue is attractive to the public in that it offers a chance for large gains if the venture is successful. Bond-issues have been put out by mining companies. However, this is usually done by only the largest companies, such as the New Cornelia Copper Co., the Inspiration Consolidated Copper Co., the Kennecott Copper Corporation, and others that have ample material assets to serve as security for the issue. The tendency is for these companies to retire the bonds as quickly as possible, either by paying them off or exchanging them for stock. The New Cornelia Copper Co. is capitalized for \$8,000,000 in shares of a par value of \$5; bonds to the amount of \$4,000,000 were issued to pay for equipment and construction work; these bonds were to run for 12 years and paid 6% interest.

The capital stock of a company is the total amount that it can issue under the terms of its charter, and bears no necessary relation to the amount of stock actually issued or subscribed for. A company may have a total capital stock of \$1,000,000 and yet only half might be issued, the remainder being kept for later use. The outstanding stock is \$500,000, but the capital stock is always \$1,000,000. Dividends are paid only on issued stock. Unissued stock represents nothing but the right to issue. If sold it brings in cash but the stock carries with it an interest in the company that should equal the price received for the stock. Thus the increase in assets and liabilities is just equal.

Formerly the law required that all the capital stock must be issued and paid for, but now State statutes vary, and usually only part of the capital stock has to be paid up within a stated time. A share of stock represents an interest in the company, and its true worth depends only upon the earning power of the company. For this reason the face or 'par' value of a share has in reality little meaning, and speaking of stock as above or below par simply means that the financial condition of the company is considered to be either good or poor. A share is worth only its proportional part of the whole corporation no matter what the par value may be. There is a growing tendency to issue stock having no par value. This is a good plan as it would force an investor to investigate the financial standing of the company before taking an interest in it. The Minerals Separation North American Cor-

poration was chartered in 1917 to facilitate the conduct of business in this country by the parent English concern; its capital consists of 500,000 shares of no par value, which were placed in a 5-year voting trust.

When capital is represented by only one kind of stock it is called common stock. Often the common stockholder is uninformed regarding the financial condition of his company. He has the right to vote for directors who are supposed to represent him, and his ownership of stock entitles him to his proportionate share of any dividends that may be paid. The company's reports may convey no real information concerning the condition of affairs. Recent court decisions make it possible for the stockholder to inspect the stock-ledger and transfer-books of the company for the purpose of getting a list of the other stockholders so that he can communicate with them. He also has a right to inspect the books of the concern when it is consistent with the interests of the company, but so many obstacles can be thrown in the way of such an inspection that this right can seldom be realized.

The idea that unissued stock is the same as treasury stock is prevalent, but incorrect. Unissued stock is merely the privilege of creating a liability. In one State the payment of \$20 will charter a company and authorize an issue of stock up to \$20,000,000. Such a company would have an over-supply of unissued stock, but no assets at all. When stock has been issued and fully paid for and then comes back into the treasury of the company, either through purchase or donation, it is rightly called treasury-stock and can be sold to bring in cash, for it has a definite value, yet it cannot be voted by the company nor can dividends be paid upon it.

Preferred stock is stock that is given some preference over common stock in regard to profits and often in regard to assets in case of liquidation of the company. Usually it is guaranteed as to dividends, and these dividends are cumulative, that is, if not paid when due the amount remains as a liability of the company and all preferred-stock dividends must be paid before a dividend can be declared on the common stock. It is often arranged that preferred stock is subject to redemption at a premium ranging from 5 to 20%. A common protection for preferred stock is the requirement that the company must maintain a certain ratio of current assets to liabilities, of net surplus to capital, and of dividends to surplus. In one concern, quick or easily realizable assets must be maintained at a minimum of \$140 per share of preferred stock. Additional issues of preferred stock cannot be put out at more than two-thirds the cost of improvements and the increased capital. Preferred stockholders may have a right to vote. In some cases they come into control of the board of directors if dividends are not paid when due. Public-service corporations and industrial companies are more likely to issue preferred stock than mining companies. Preferred stock is sometimes issued by large mining companies, which control a number of mines or reduction plants, for the purpose of making extensions of plant or acquiring new property. The American Smelting & Refining Co. has a total capitalization of \$115,000,000, which is divided into \$65,000,000 of common

stock and \$50,000,000 of 7% cumulative preferred stock. The shares are of \$100 par value. The United States Smelting, Refining & Mining Co. has a capitalization of \$75,000,000 in \$50 shares; of this, \$37,000,000 is in 7% cumulative preferred stock.

Should a company earn large profits there is a possibility that the common stock might receive a larger dividend than the preferred stock, since the preferred-stock dividend is limited to a specified amount. For this reason, a provision is sometimes made that after a dividend equal to that paid on the preferred stock has been paid on the common stock, all dividends above these requirements are shared equally by the two issues. If preferred stock is made cumulative as to assets it would prevent some outside interest from buying up the low-priced common stock and electing their own directors and then selling the property of the company. Unless cumulative as to assets, the preferred stock would have to share equally with the common stock, which might have little value because of poor dividend prospects.

PROMOTERS AND PROMOTION. The promoter of stock companies performs a necessary and useful function in the business world. Taken in the proper sense of the word, the promoter's field is to bring together capital and an enterprise in which capital can be usefully and profitably employed. He finds the opportunity and then turns it into a reality. So many fake schemes and unfortunate promotions have been inflicted on the public that the term 'promoter' is often regarded as one of reproach.

The work of the promoter may be divided into three stages: investigation, assembling, and financing. When a promising discovery has been made, the promoter must make a thorough investigation of the enterprise to test its possibilities. In large projects, engineers are employed to make a detailed survey of conditions and to draw up estimates of cost. No stone should be left unturned in the effort to view the project from all angles and to weigh carefully each disadvantage. Only in this way can correct judgment be passed on the enterprise. If the final judgment is favorable, the next step is to assemble the essential elements. This means securing all rights and options, chartering the new company, forming the financial plan, and preparing to sell the securities. All this takes time, and may require the spending of a large sum of money. Capitalists cannot be interested unless the project is in definite form. Then, for his own protection, the promoter must be secured in his title to rights and options. Instances have been known where the promoter had outlined his plan to a financier who had listened carefully but refused to supply funds, only to secure the options for himself as soon as the promoter had gone. The final step is the selling of the securities and getting the enterprise under way. To carry his work to a successful conclusion the promoter must understand his business thoroughly; he should possess tact and patience; he must have a good knowledge of men, as well as abundant energy and great perseverance. He runs large risks, and it is only fair that he be properly compensated. His continued success as a promoter depends upon his making

money for his clients; for this reason he cannot engage in crooked work or be dishonest in his dealings. An honest promoter is always willing to supply any desired information to interested persons.

Although the mining promoter may interest himself in the claims of a prospector who needs money to develop his holding, most mining promotions are concerned with the sale of developed mines or the re-opening of abandoned properties because of improved market conditions or the discovery of a more suitable process for treating the ore. Owing to the element of speculation that is always involved in mining, the general public has suffered severely at the hands of unscrupulous mining promoters. Either because of ignorance or of failure to investigate, the most flashy advertisements and grossly exaggerated statements are believed, and hard-earned money is foolishly wasted. 'Blue-sky' laws in many States and the activities of the Federal postal authorities serve to curtail to some extent the operations of these fakers, but nothing short of educating prospective victims can put an end to their nefarious business. If the investor can determine the answer to the following six questions, he will have practically all the information he needs to pass intelligent judgment upon the merit of the proposition.

1. Is the promoter honest and in good standing among business men who know him?
2. Has the company a clear title to the property it is represented to own?
3. Has the property been developed so that the actual tonnage of ore and its mineral content are known, and have these figures been determined by a reputable engineer?
4. Has the proper treatment of the ore been worked out by a competent metallurgist?
5. Is the proposed capitalization ample to cover cost of property, the proposed plant, and, in addition, to supply adequate working capital?
6. Is the direction or management of the company in the hands of capable men?

An honest promoter is always willing to furnish trustworthy references. Information regarding men connected with the enterprise can be obtained from merchants, bankers, and editors of the technical press or of the mining department of newspapers. Many States maintain mining bureaus, which can supply valuable information to the investor. The technical press is often the source of useful information. Reports by reputable engineers on certain mining districts are available to those who are sincerely interested. The U. S. Geological Survey has published maps and reports on the mineral resources of many parts of the country. These reports can be obtained free of charge by addressing the Director, U. S. Geological Survey, Washington, D. C., or for a nominal sum from the Superintendent of Documents, Washington, D. C. If much money is to be invested it is advisable to employ a mining engineer to make an independent examination. Several prospective investors may club together to defray an expense of this kind. The true seeker for information will be able to learn much for, "The Lord helps them who help themselves".

Mining in the Ketchikan District

By JOSEPH ULMER

*The man who made the first mineral location in south-eastern Alaska was Charles Vincent Baranovich. He came to Alaska in the early 'sixties and married the daughter of Francois, cook for the garrison of Russian soldiers stationed at Fort Wrangell. His wife was born in the stockade, remnants of which are still visible. Baranovich engaged in trading with the natives, and in 1865 was granted a concession at Karta bay; his being one of the 21 concessions granted by the Russian government.

Baranovich established a trading-post at Karta bay, to which natives from Tolstoy, Wrangell, and even as far away at Sitka brought furs and skins. When the weather was stormy, the natives took their goods overland from Tolstoy bay to the entrance of the Salt Chuck, where they built signal-fires which brought Baranovich to meet them. On the point where so many of these signal-fires were made, the land is to this day devoid of all timber except second-growth and brush.

On one occasion, Baranovich planned to send the schooner 'Kasol' on a trading-voyage to Kodiak. Captain Kane, afterward for many years the pilot of United States revenue-cutters in Alaska, then a lad of nineteen, was the super-cargo of the 'Kasol'. The vessel was fitted out for this voyage at Victoria, B. C. While at Kodiak the crew, all Russians, mutinied and went ashore. After waiting three days in hopes that the mutineers would return, Kane went ashore to hire a new crew, and while he was gathering his recruits, the old crew went aboard the schooner at night, took possession, and sailed her to the westward, where they sold the cargo and bought five thousand seal-skins, which they sold for \$1.50 each. Baranovich heard nothing of the 'Kasol' until he made his way to Kodiak, where he found the schooner abandoned, the mutineers having stripped her of everything, even the sails. The captain of the schooner was at Kodiak in a dying condition. Baranovich repaired and fitted up the 'Kasol' at Kodiak and then sailed her back to Karta bay.

In 1867, Baranovich located the Copper Queen mining claim, which was the first mineral location to be made in south-eastern Alaska, near the present site of New Kasaan. Years later, the claim was taken up by William Bunard, who is still living at Kasaan—a pioneer of nearly four score years and ten.

In 1900, U. S. Rush and George Brown, who had gone overland from the States to the upper Stikine River country, went down the river from Telegraph creek to Wrangell, where they got a rowboat and an outfit and started out on a prospecting trip on Prince of Wales island. They followed the shores of Kasaan bay into

the Salt Chuck, where they found mineralized float, which they followed up and located the group of claims known as the Rush & Brown mine. These claims have been worked continuously since their location and have produced many thousand tons of copper ore. This mine is on two parallel shear-zones, and has chambers of magnetite carrying from 2 to 4% copper. The workings are now down to a depth of 400 ft., the ore maintaining its former width and value.

About the same year, Sam Lichenstadter, on his way

PART OF ALASKA

out from Dawson, met a Captain Crooks, who told Lichenstadter that while he was hunting in the Kasaan hills in the 'seventies he had found croppings of copper ore on the trip out from Dawson. Captain Crooks died, and Lichenstadter, who had come to Alaska as the representative of some London financiers, came to Ketchikan, where he got Ed Doolittle, F. F. Black, Harry Trimble, and Joe Johnson to go with him to Kasaan bay, where they made locations in behalf of their employer, naming the mine Mt. Andrews, in honor of Lichenstadter's backer. This was the real beginning of the mining era in the Ketchikan district. Work was started on the new discovery, and news of the resources of the district went broadcast.

*From 'The Pathfinder', of August 1920.

C. W. Fickert, who had come from Wrangell in 1899, and was hauling supplies to the Mt. Andrews in a sailing sloop called the 'Mamie', had prospected in the States, and decided to try his luck here, so he took a trip over the hills and, although he had been discouraged by the men working at the Mt. Andrews, he discovered the Mamie mine. Bob Allison, who had a half-interest in the sloop, was 'located in' as a half-owner of the Mamie, which half-interest he sold to James L. Freeburn, and Fickert sold his half-interest to Sam Silverman of New York. Chris Aus discovered the Stevenstown mine, which Silverman later acquired.

To operate the Mamie and Stevenstown the smelter at Hadley was built, and for several years Hadley was the most active mining centre in this part of Alaska.

The Mt. Andrews mine, which has produced a large tonnage of ore, was leased to R. W. Rogers, and is now held by an estate in London. The Mamie mine and Hadley smelter were purchased by the Granby Consolidated company, which shipped the ore to the smelter at Anyox, where it was used principally as a flux. Owing to the decline in the price of copper and the high cost of operation, the mine was shut down, although it produced sufficient ore to make it a profitable speculation.

The Goldstream group is a gold-producing property, located on the west arm of Tongass Narrows, Gravina island. The original claims, Goldstone, Goldstream, and Blue Bird, were discovered on December 15, 1902, and located on January 2, 1903, by Otto Miller and L. G. Phillips, and the Rose and Lilly on March 3, 1903. Charles D. Lane took the first bond on the property on October 13, 1903, and did considerable work. This property has been sold to several different parties, each working it for a time, and it is estimated by men who were in close touch with the operations that nearly \$200,000 has been taken out. The mine is easily accessible, and if economy is applied, can be put on a paying basis.

The Jumbo and Copper Mountain properties produced a large tonnage up to 1919, but owing to the untimely death of Charles A. Sulzer, who was manager for the Alaska Industrial Company, the properties were closed, awaiting the settlement of the Sulzer estate. New York parties under the management of Captain Jones are now negotiating for re-opening these mines.

The Niblack copper mine, at Moira sound, has shipped about 400,000 tons of ore. The property is owned by the Wakefield estate. A. A. Wakefield, the pioneer mining engineer of this section, is at present doing preliminary work.

The Kasaan Gold Co. has purchased the Dunton gold mines from J. H. Rodgers of St. Louis, Missouri. This property, which is known locally as the Harris Creek mine, near Hollis, Prince of Wales island, was discovered by B. F. Redmond in 1908. Mr. Redmond, who is still living at Hollis, is 73 years old. The new company, under the management and supervision of M. M. Reese and Sidney Drake, installed a ball-mill, extra sets of plates, concentrating tables, and flotation plant, increasing the capacity to 100 tons per day. It has also a newly-built

bunkhouse and messhouse. The mine connects with tide-water by a 3000-ft. surface tram. The shaft is down 410 ft., and drifts and laterals are driven along the vein to about 2000 ft. About 9000 tons of ore has been mined and milled, giving a recovery of \$106,140. Approximately 100,000 tons of ore is blocked out.

The It mine at Kasaan bay was discovered in 1906 by William E. Taylor. J. C. Barber and H. C. Strong of Ketchikan developed the mine and sold it to the Granby Consolidated in 1913, which extracted over one and a half million dollars worth of ore. It was mainly used as flux at the company's smelter at Anyox. The property was shut down about a year ago.

The Salchuck mine, formerly the Goodro mine, was discovered by Young Walter Thomas on August 29, 1906, while out prospecting with Si Goodro. The first five claims were called the Joker group. The ore occurs in gabbro, cut by diabase dikes in no defined vein system, usually along fracture-zones. The principal ores are bornite and chalcopyrite, containing gold and palladium. The property is owned by the Salchuck Mining Company. A 150-ton flotation plant, near the head of the Salchuck, on Karta bay, is connected with the mine by a surface tram and a 1200-ft. adit.

There are a great number of undeveloped prospects in the Ketchikan mining district. None of the surrounding country has been thoroughly prospected. Mention is made here of Antone Denomie who won first place as the pioneer prospector of this section. He was sent by Major Baldwin, of Minnesota, to Valdez in 1898, then came to this district and discovered ore in the Karta Lake district. From Karta bay he went to the Portland Canal in 1906 and discovered the Indian mine on the Salmon river, thereby leading to the discovery of the famous Premier mine by William (Scotty) Dillsworth.

Ketchikan was the centre of mining activity 15 years ago, and bids fair in the near future again to be the hub for south-eastern Alaska. Ketchikan, the nearest distributing point for Hyder, at the head of Portland Canal, is the gateway to the great mineral belt extending from the head of Portland Canal to the north-west along the coast range, with its connecting avenues, the Unuk and Chickamin rivers. The Territorial Road Commission, the U. S. Bureau of Public Roads, and the U. S. Forest Service are co-operating to build trails and roads for prospectors.

THE first inspection of the shot that has misfired should be to determine whether or not the cause be outside of the drill-hole. It may be that the fuse has not burned to the mouth of the drill-hole, or that the legs of the electric device (electric detonator or electric igniter), or the leading-wire is short-circuited or open-circuited outside the drill-hole, or that the blasting-machine did not provide adequate current. If the cause lies outside of the drill-hole, it may be remedied without disturbing the charge. When a misfire has occurred in a hole containing an electric device, the blasting-machine should first be promptly disconnected and removed.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

INSPIRATION SUES FOR REFUND OF TAXES.

GLOBE-MIAMI DISTRICT.—What is probably the biggest suit involving taxes ever instituted in the State of Arizona has been started by the Inspiration Con. Copper Co. and the International Smelter Co. for a refund of over one million dollars paid in excess taxes in the years 1917, 1918, and 1919. The Inspiration's suit alone calls for a refund of \$1,264,406, and the suit is filed in two different complaints calling for a refund of \$694,224 for the year 1918, and \$570,182 for the year 1919. The International Smelter Co. has petitioned in three different suits for about \$165,000. In the petitions filed by their attorneys the companies claim that the State Tax Commission, sitting as a board of equalization, raised the valuations of their properties unconstitutionally, after the rate had been fixed by the county assessor and the Gila county board of supervisors, sitting as a county board of equalization. The Gibson Consolidated Copper Co. has temporarily closed down and it is reported operations will not be resumed until a better copper market develops. The management re-timbered the shaft and workings so that the property would not suffer during the enforced idleness. A pumpman is being retained to keep the workings from being flooded. At a meeting of the employees of the Arizona Commercial at Copper Hill, who went on strike last week, because of differences between the superintendent and the mine foreman, it was decided by a vote of ten to one to return to work immediately. Joseph Lord, Federal mediator connected with the Department of Labor, met with the men and was influential in bringing about an adjustment of the affair.

SUPERIOR DISTRICT.—The Magma Copper Co. has cross-cut on the 1800-ft. level to the west and is reported to have found 11 ft. of ore averaging 13% copper. Cross-cutting is still going on. The company has purchased seven claims to the west of the property, known as Magma Extension claims.

PHOENIX.—With the excavation work completed and eight carloads of material ready on the ground, the Arizona Gypsum Co. announced that operations on the construction of its \$300,000 plant, six miles east of Phoenix, will be under way within the next few days. It is expected that the plant will be completed and operating in three months.

SUPERSTITION MOUNTAIN DISTRICT.—It is reported that a \$25,000 mill is to be erected on East Pinto on a promising gold strike which was recently opened there. The

property is reached by a wagon-road from the Goldfield side of Superstition mountains. The old Goldfield property, at the base of the Superstition mountains on the west side, is being revived. The property is controlled by George U. Young, secretary of Arizona during its last years as a Territory, and development is now under way. The property has been a large producer of gold in the past. The Silver King has been closed down on account of financial difficulties.

JEROME.—The tunnel at the Shea mine has penetrated the orebody that was opened on the 325-ft. level. The ore in the tunnel carries chalcopryite which is replacing tetrahedrite and is over 6 ft. wide, assaying 0.40 oz. gold, 20 to 30 oz. silver, and 9% copper. The shaft and raise will be connected by the next round or two. It is reported that a rich strike of chalcopryite ore has been made on the 1600-ft. level of the Jerome-Central mine. This property is one and a half miles south of Jerome.

GLOBE.—A 21-in. vein of full three-inch fibre-asbestos has been developed on the property of the Globe Asbestos Co., in the Chrysotile district. Seven tons of long-fibre asbestos has been shipped in the last few months and about 40 tons is blocked out. The mine is 64 miles from Globe, and transportation difficulties have caused serious consideration of some form of aerial transportation for the product of the three asbestos properties in the district. On September 1 the Van Dyke Copper Co. started the lateral development and exploration called for in its original program. Operations have been confined, until recently, to sinking the shaft, which has reached a depth of 1692 ft., and is the deepest in the Miami district. This great depth, compared with the shafts of the Inspiration and Miami companies, was necessitated by the fact that the eastern extension of the orebodies of the district has been faulted downward several hundred feet by the Miami fault. Shaft stations were cut at 1212 and 1550 ft. below the collar of the shaft, and the work is being carried on from these stations. Work on the 1212-ft. level is all in ore, in the orebody discovered by drilling and later penetrated by the shaft, where it was found to be 40 ft. in depth. On the 1550-ft. level a drift is being driven in the zone of mineralization.

TUCSON.—Facing the prospect of a shut-down of their enterprises, which they declare will result if the recent increase in freight-rates authorized by the Interstate Commerce Commission are put into effect, representatives of mining and smelting interests in southern Arizona and New Mexico met in conference last week with

representatives of the traffic departments of the railroads. Railroad traffic managers admitted the seriousness of the situation that confronts the mining men, but contended that the advanced cost in moving ores should not be blamed entirely upon the railroads. One railroad representative pointed out that cost of labor, material, and supplies for mines has advanced in many cases as much as 100% during a period that freight-rates have advanced only 50%. In the case of mines situated at points distant from railroads, he said, the cost of transporting the ore to the railroads has also advanced.

KINGMAN.—The shaft of the McCracken mine has now reached a depth of 600 ft. and has developed a large flow of water, which necessitates the immediate installation of pumping machinery. This water will prove of great benefit to the mine, as there has not been sufficient for milling-purposes and therefore the former operators erected their mill at Signal. J. C. Rankin announces that the shaft of the Payroll mine is to be re-timbered to the 200-ft. level, the timbering below that point being in good condition. The shaft is to be sunk to the 600-ft. level and the upper levels developed further. Most of the milling-machinery of the C. O. D. company's mill has arrived at Kingman. The shaft is now down 430 ft. and preparations are being made to mine the ore opened between the 300 and 400-ft. levels. The mill of the Kingman Consolidated Mining Co. at Stockton Hill is now operating. The machinery for the new power-plant at the tunnel-site has arrived.

NOGALES.—Two teams are steadily engaged in hauling high-grade lead-silver ore from the Tom Gardner and Lander Young lease at the Hardshell mine to Patagonia. The present rate of production is two carloads per week. It is said that there is 4 ft. of solid galena ore opened on the 325-ft. level. The Consolidated Southern Arizona Mining Co. is to unwater the old Mansfield properties, of which they are owners, with a view to the examination of the lower workings. The old shaft is down 360 ft. It is probable that the Richardson property recently optioned by the Consolidated will be developed from the old shaft of the Mansfield.

OATMAN.—The apex suit brought by the Tom Reed Gold Mines Co., involving the Big Jim vein, has been set for hearing before Judge Bollinger on October 4. The basis of the suit is the contention that the Big Jim vein apexes on the ground of the Tom Reed and that it has been faulted into United Eastern ground. The Tom Reed drift from the Aztec shaft on the 400-ft. level has been driven eastward 150 ft. toward the United American end-line. The United American has cut a station on the 170-ft. level, and cross-cutting on the 500-ft. level toward the vein has commenced. It is expected the vein will be cut about October 15.

WILLCOX.—The Central Copper Co. now has over 100 men upon its payroll and is rapidly completing the new road across the Dos Cabezas mountains from the Mascot to the Elma orebody. There remains 3000 ft. of the 18,000 ft. of road to be completed. It is expected that operations will be commenced at the mine by October.

The Grand Reef mine, situated in the Aravaipa mining district 60 miles north of Willcox, owned by R. V. Dey of New York, is reported to have been purchased by the Aravaipa Leasing Co., which is controlled by the American Lead & Zinc Company.

COLORADO

RAILROADS WILL NOT INCREASE LOCAL FREIGHT-RATES.

CRIPPLE CREEK.—A five year lease on the Pharmacist mine, Bull Hill, has been given by the Pharmacist G. M. Co. to L. F. Le Brun and associates operating the South Burns mine of the Acacia G. M. Co., adjoining. Le Brun is drifting into the Pharmacist from the 1200-ft. level, of the Burns Enite. Cresson and Portland continue to be the largest shippers of the district.

LEADVILLE.—Railroad officials have announced that freight-rates to Colorado points will not be increased and that steps will be taken to nullify the interstate increase, but that the subject must be referred to the Interstate Commerce Commission before action is taken.

WELD COUNTY.—A potash deposit has been discovered and located in Hunter's Lake, $3\frac{1}{2}$ miles west of Stoneham in this country by the Mentgen brothers of Sterling, and the Stoneham Potash Development Co. has been organized and incorporated for its development. Tests made by Louis D. Gentzler show from 50 to 68% potash in the crude material. The deposit covers more than 200 acres and the company has secured a long-time lease on 30,000 acres of land in proximity to the lake, which is known to contain coal.

CENTRAL CITY.—Gold ore assaying 13 oz. per ton has been discovered in Travellers gulch, near this city, by Peterson and Nearseter. The streak is reported to be 18 in. wide at the grass roots. Ore has been found in the Jack Rabbit tunnel in Twelve Mile. It contains \$23 in gold, 30 oz. silver per ton, and some copper.

ALMA.—Ore assaying 160 oz. silver, 25% lead, and a little gold has been found in the Red Lion. The Dolly Varden, re-opened by the Louisiana-Colorado syndicate, with A. E. Moynahan former district mine inspector as superintendent, is the scene of a rich silver discovery. The ore assays from 400 to 600 oz. silver per ton. The May Queen is driving a tunnel from Buckskin gulch into Mt. Bross. A big body of milling-ore has been opened on the Hock Hocking on the Mosquito slope of Pennsylvania mountain. It is reported that operations will be resumed shortly in the Denver-Leadville tunnel on Mt. Loveland. The Hill Top mine is producing silver-lead ore steadily.

MICHIGAN

DRAINAGE OF SWAMPS TO REDUCE PUMPING IN CALUMET MINES.

CALUMET.—Arcadian Consolidated's New Baltic shaft has a splendid showing at a depth of 600 ft. where the vein was penetrated by the cross-cut 15 ft. from the shaft. The vein is heavily mineralized, excepting one foot, from the foot to the hanging wall and its width is 18 ft. The showing is considered the best ever opened in

the property, the ore being richer than that found on the 400 and 500-ft. levels. The 600-ft. level will not be developed at present and sinking will be continued to the 700-ft. level before explorations on the vein are resumed. The objective is the 900-ft. level, from which a drift will be started to connect with the New Arcadian shaft at a corresponding depth. There is evidence that the vein is approaching the shaft and in the event this proves to be the case no cross-cutting will be necessary. There is no faulting anywhere in the shaft and no difficulties are anticipated from such a source. As the 'rock' in the New Arcadian shaft is similar to that in the Baltic, and the ground in the latter has been proved to at least 600 ft., it is believed that the Arcadian has 3500 ft. of ground containing an unusually rich vein. The discoveries at New Baltic are considered the most important since the Baltic lode was developed, because the operations are far east of any producing mine. The shaft is more than a mile north of the old Arcadian shaft. It is proposed to continue development work through the winter if general conditions improve.

To keep as much water out of the mines as possible, numerous drainage-projects are under way in the north end of the district. Practically all of the water that is found in the mines comes from the surface and that which is found in the lower levels, even far below the level of Lake Superior, is negligible. The draining of the North Tamarack reservoir and the tract of swamp land west of the Hecla shafts by the Calumet & Hecla is a part of this plan. Allouez and Wolverine are draining old ponds also. As an indication of the size of the water problem, it may be mentioned that bailers of 2000 gal. capacity are operating in No. 5 Tamarack and Red Jacket shafts, in addition to the 1,000,000 gal. pumped every day. No. 5 Tamarack is used for bailing and until the haulage-tunnel is completed far enough to permit the placing of pumps in No. 12, it is impossible to resume mining in it. Because of the flow of water at No. 5, no mining has been done below the 40th level, but once the water is no longer troublesome the ground in that territory will be developed through sub-shafts. Wolverine also has had considerable trouble with water, but at present the flow is being taken care of. Within one year the company has been forced to spend nearly \$15,000 to handle the accumulation of South Kearsarge water, for upward of 12,000,000 gal. had to be pumped to keep the lower levels dry. The flow of water is so great that operations cannot be carried on below the 38th level.

Mohawk maintains its daily tonnage of from 1700 to 2000 tons per day. The program of development now in effect will be followed until there is material improvement in conditions and there is a hope it will be broadened later to include the development of new ground.

Copper Range is carrying a slightly larger metal surplus than was reported 60 days ago and approximately 5,000,000 lb. of refined copper is on the docks and in process of refining. This compares with about 4,000,000 lb. at the end of last year. There is comparatively little change in operations at the three mines, Champion, Trimountain, and Baltic, and the underground forces have

not increased during the past month. At the same time development work continues slightly above the rate for the corresponding period of 1919, and with the yield at about the same high figures—45 lb. per ton from Champion, 35 from Baltic, and 30 from Trimountain. During the past year, Copper Range has been adding re-grinding apparatus in connection with the effort to reduce the already small losses. About 40 tables have been added to the equipment of the Baltic and Champion mills. This will increase the recovery considerably, but it is by no means the final effort. There is a possibility that Copper Range will add flotation units to its re-grinding equip-

MAP OF CENTRAL ARIZONA

ment just as soon as the cost of steel and other supplies return to somewhere near normal figures.

Seneca is cross-cutting the plat for the 5th level and by the middle of October it is expected that drifting will be started. The north drifts on the third and fourth levels are being pushed forward and the grade of the ore during the past week was satisfactory. The south drift on the fourth level is about 50 ft. from the Ahmeek boundary. Although recently the ore has been low-grade, it is not considered discouraging.

NEVADA

FLOTATION MILL AT GERLACH NEARLY COMPLETED.

AUSTIN.—The Warner, in Washington canyon, 30 miles south of here, has been developed into an important mine by the sole owner, Mrs. Rose Warner, who has furnished all of the money for development. Mrs. Warner owns 21 claims. The vein, averaging 13 ft. wide, after being opened by several tunnels to a depth of 350 ft. on the dip, was cut recently in a 95-ft. shaft 600 ft. from the outcrop. The ore contains only a small proportion of gold, is free-milling, and is found as a replacement of limestone. The mine is 25 miles from Ledlie, on the Nevada Central, the nearest shipping point. Some of the drifts from the tunnels have opened rich ore. In a drift from tunnel No. 3 from 2 to 4 ft. of ore assaying \$250 per ton is exposed. Other similar high-grade pockets have

been found, but the value of the mine is in the average-grade of the ore. Work has been started on another vein, 1500 ft. from the 95-ft., or New Hope, shaft, and ore assaying 500 oz. silver has been found near the surface. The mine has been developed for two years, the work being in charge of William M. Thacher, manager for Mrs. Warner.

GOLD PARK.—Most of the machinery for a 50-ton mill has been hauled to the Star of the West at Gold Park, in the south-western part of Lander county, and is being erected. It is expected to have the plant operating in two months. The Star of the West company, of which Robert B. Todd of Reno is president, is operating an old gold-silver-lead mine that has been re-opened. Amalgamation, concentration, and oil-flotation will be used in the mill. A new gold-find is reported 10 miles west of here, near Pilot, where an average of 84 samples taken from a 70-ft. shaft gave an average assay return of \$79.20 in gold, according to persons interested in the new district. The formation is described as "a basic andesite, with the vein making in a shear-zone 200 ft. from a rhyolite contact". The claims on which the find was made are owned by Robert Burns and others, who started work in a 16-ft. shaft several months ago and continued it to a depth of 70 ft. A drift has been driven 65 ft. from the bottom of the shaft and in it there is an 18-in. vein of gold ore assaying \$500 to \$900 in gold and 50 to 100 oz. silver.

GERLACH.—A 50-ton flotation-plant has been practically completed by the Leadville Mines 40 miles north of here and it is expected the plant will be in operation before October 15, according to A. A. Codd of Reno, president and manager of the company. The Leadville has been treating silver-lead ore in a concentrator, which the flotation-plant will replace. The new plant will contain a Blake crusher, Marcy ball-mill, Dorr classifier, Colburn flotation-machine, and an Oliver filter. The main function of the filter will be to save water. The machinery will be driven by a 100-hp. engine.

VIRGINIA CITY.—The miners have returned to work in all but the Gold Hill mines, receiving the \$1 increase to \$6 per day demanded. R. A. Hardy, manager for the United Comstock at Gold Hill, in a statement, declared that if the increase demanded were granted it would "wipe out any possibility of profit from the ore in sight and make the whole venture so precarious and unattractive that it could not be continued at the present time". He said the only solution appeared to be "some system of group contracts under which the men would receive compensation in proportion to their efforts". The 'bonanza' winze from the 2150-ft. level of the Consolidated Virginia has been sunk 40 ft. and during last week there was produced from it 88 tons of ore assaying \$86. Some of the ore from this winze has assayed more than \$1000 per ton in mine carloads lots.

NATIONAL.—A shipment of 18,634 lb. of ore from the Bell-Prour lease on the Buckskin National gave a smelter return of \$134 in gold and \$252 in silver per ton. The ore was mined from a 6-ft. vein containing the thin seams

of almost solid metal for which the district is noted. The lessees cut the vein at a depth of 350 ft. by driving an 800-ft. tunnel and a winze is being sunk in the ore.

GOLDFIELD.—The Silver Pick is raising from a depth of 110 ft. in the leased Red Top mine of the Development and indications are that shipments will be started to the Development mill within 20 days, according to Mat Murphy, superintendent for the Silver Pick. Miners that worked for the Consolidated in 1913 reported that there was ore in a stope extending to the surface when they were driven from it by caving ground and these statements were verified recently when Murphy entered the caved area by climbing down the stope from the surface. A 90-ft. drift was driven in the foot-wall of the vein near the caved ground and it broke into an old drift which is impassable near the Red Top shaft. The walls of the old drift were found to be standing well near the stope, but it was half filled with sand washed in by a storm. Tracks were laid on the sand, the roof of the drift was shot away and a raise that should enter the stope in 40 ft. has been started. When he entered the stope from the surface Murphy sampled two 5-ft. widths which gave assay returns of \$22 and \$111 respectively. He says the hanging wall of the stope is in good condition and that there will be no trouble in exploring it. George Meuli, a lessee on the Lone Star, has abandoned his plan to build a mill on Lone Star ground and has secured a site in the southern part of the town of Goldfield. He has ordered a Gibson mill which will treat 10 to 12 tons of ore daily.

NEW MEXICO

MINING COMPANIES PAY MOST OF THE TAXES IN GRANT COUNTY.

PINOS ALTOS.—Considerable development work is being done on the Bald Back mine, situated a mile from the famous Silver Cell mine in the Pinos Altos district.

SILVER CITY.—The New Mexico Mining Association was organized on September 9 and is preparing to make formal application to the American Mining Congress for a charter which will permit the temporary organization to become the New Mexico Chapter of the American Mining Congress. John M. Sully is chairman of the executive committee.

Of the \$35,476,000 assessed valuation in Grant county, 61.3%, or \$21,733,551, represents property of three only of the mining companies. The remaining 38.7% is made up of all other property in the county, including livestock, farms, city property, personal property, railroads, banks, and the smaller mines. The three companies referred to are the Chino, assessed at \$18,333,946, including real and personal property and net output; the Phelps Dodge Corporation (Burro Mountain branch), assessed at \$2,973,545; and the Empire Zinc Co., assessed at \$436,042. A similar condition is reported to exist in McKinley county. There the taxes on \$7,700,000 of the assessed valuation of \$11,000,000 are paid by 12 leading companies, including some mercantile establishments and the railroads, leaving to all the rest of the county the payment of taxes on only a little more than \$3,000,000.

UTAH

TINTIC STANDARD PASSES DIVIDEND.

FRISCO.—John Amsden and Wm. Webb have secured a contract from the Consolidated Nevada-Utah Corporation for a considerable amount of development work on the company's property near here known as the Imperial group.

AMERICAN FORK.—Geo. E. Hemphill, manager for the American Consolidated Mines Co., in American Fork canyon, reports that the company is shipping a high-grade silver-lead product, averaging from 40 to 50% lead and 15 oz. in silver. The vein from which the product is being mined is about 2 ft. wide.

ALTA.—R. O. Dobbs, general manager for the Louise Mining Co., reports that an important discovery has been made in the drift west of the second raise in the Maggie adit. The new find is a high-grade copper-silver-lead carbonate, only about 15 ft. below the contact, where a larger orebody should be developed. About 40 ft. of drifting remains before reaching one of the objectives, where development above has shown conditions indicating an orebody at the intersection of the cross-fissure with the main body. A contract has been let for hauling the ore to the railway a mile away.

BIG COTTONWOOD CANYON.—The Cardiff Mining Co. is shipping approximately 65 tons of ore per day, according to Lynn Thompson, engineer for the company. The ore is coming from the 800-ft. level. Pumps were started recently to unwater the mine below this level and it is expected that shipments will be made soon from the deeper workings. The ore averages about \$60 per ton. Thos. Prichard, in charge of operations at the Big Cottonwood Bonanza property, reports the cutting of the Bonanza fissure, one of the present objectives. The fissure was cut by a drift 275 ft. long. The vein-matter is principally manganese and iron, with large seams of spar. The foot-wall is quartzite and the hanging wall limestone. The Bonanza fissure runs northeast-southwest, and it is stated that the contact is similar to that in which the Cardiff found its main orebodies. Small seams of iron carbonate from the intersecting cross-fissure are beginning to appear, which is taken as an indication that the intersection should be reached soon.

C. R. Green, president and manager of the Victor Mining Co., states that driving west on a fissure found 1600 ft. in the Victor tunnel, has been started. Sufficient surface work has been done on the contact to demonstrate the desirability of undertaking development in depth. This is reported to be the same contact in which the Cardiff mine developed its large orebodies. From 150 to 200 ft. of work will be required to reach the objective. It is stated that the American Consolidated Copper Co., which owns the ground immediately west of the Victor, is negotiating for a right-of-way through the Victor tunnel.

PARK CITY.—Operations have been resumed at the property of the Three Kings Consolidated Mining Co. The company has recently erected a new blacksmith and carpenter shop. For several years exploration work has

been carried on at this property, and the diamond-drilling established the fact that the ore-bearing limestone so productive in the Silver King Coalition property, extends into the Three Kings formation through the Kentucky claim. The cross-cut tunnel driven on the 700-ft. level has cut seven ore-bearing fissures, traversing the formation in a northeast-southwest direction. Ore was found in fissures 1, 2, and 4. In a winze and raise in fissure No. 4 samples assayed as high as 100 oz. silver and 69% lead, while the average for the entire exposure was 28 oz. silver and 30% lead. J. R. Elliott, of Pittsburgh, who

WESTERN BORDER OF THE GREAT SALT LAKE DESERT

represents the Eastern interests in the company, is expected at the property shortly.

Five mines in this district shipped a total of 1747 tons during the week ending September 18, of which amount the Silver King Coalition shipped 618; the Judge M. & S. Co., 391; the Ontario, 392; Daly-West, 226; and the Nail-driver, 120.

James B. Allen, manager of the Glenallen property, reports that sufficient funds have been secured by the company to build a mill for treating the low-grade ores. An assessment was recently levied by the company, but as outside capital has been obtained, the assessment has been cancelled. Preparations are under way for resumption of work at the property of the New Quincy Mining Co.

Coal and supplies are being hauled to the mine, and the hoist at the Little Bell, through which the New Quincy will be developed, has been put into operation.

EUREKA.—Several months ago, L. E. Riter and associates of Salt Lake City, secured a lease on a large block of ground in the Eureka Hill mine, and then made arrangements to handle the work through the Centennial-Eureka company's 900-ft. level. A drift 181 ft. long was driven by the lessees when they found a high-grade silver-lead orebody. The drift is following the ore on its strike and at present is in ore assaying 40% lead and several hundred ounces silver per ton. Charles Baker, superintendent, reports that there is a large area of virgin ground near this new strike, and he believes future development will disclose orebodies of considerable value. For several years not much development work has been undertaken at the Eureka Hill, although at times sensationally rich ore has been struck in the property. At the North Beck property, controlled by E. J. Raddatz and associates, work is now confined to the 1600-ft. level. This is the deepest point reached from the new working-shaft, and a drift is being driven toward a break which, on the level above, carried ore and it is believed that this shoot extends to the 1600-ft. level. The North Beck people are also working the adjoining claims of the Victoria Gold Mining Co. After sinking the shaft at this property to the 600-ft. level, drifting was commenced. Bunches and streaks of good ore have been continuous for a distance of more than 150 ft. on the 1840-ft. level of the Eureka-Lilly mine, according to Grant H. Snyder, manager. This drift is being driven toward the south to open up a shoot struck on the 1640-ft. level; this shoot being over 250 ft. long on the latter level. Inasmuch as the stringers on the 1840-ft. level are appearing at a considerable distance from the objective, officials believe that the Tintic Standard ore channel will be found.

During the week ending September 18, the Chief Consolidated shipped 41 cars of ore; Tintic Standard, 28; Mammoth, 20; Dragon, 14; Eagle & Blue Bell, 8; Iron Blossom, 7; Iron King, 6; Gemini, 4; Swansea, 4; Gold Chain, 3; Grand Central, 3; Bullion-Beck, 3; Victoria, 3; Centennial-Eureka, 1; Ridge & Valley, 1; Griggs-Huish, 1, making a total of 147 carloads, as compared with 142 for the previous week.

By a unanimous vote, the board of directors of the Tintic Standard Mining Co. passed the quarterly dividend at their meeting in Salt Lake City on September 20. W. I. Snyder, vice-president of the company, issued a statement to the stockholders, stating that the principal reason for passing the dividend was the large expenditures made recently in connection with the construction of the mill and railroad; the two items aggregating \$360,000. During the first eight months of the current year, the net earnings of the company totalled \$624,062. Two dividends, aggregating \$234,040, have been paid out of current earnings, during that period. Labor during the past few months has been scarce, and the mine has been running with less than 60% of the force that could be employed to advantage. E. J. Rad-

datz, president, says that never in the history of the mine has there been a greater quantity of first-class ore in sight than at the present time, and after the crops are harvested and state-road work reduced, it is believed additional labor will be available for the mines in this district.

WISCONSIN

NEW DEVELOPMENTS NEAR CUBA CITY.

LIVINGSTON.—The Fearless Mining Co., Sam Altenberg, superintendent, has acquired the Squirrel mine formerly under the management of the B. M. & B. Mining Co. The mine has been further developed, the surface rig overhauled and put into service, and shipments of zinc ore are now being made. J. B. Piquette, president of the Fearless Mining Co., has secured the support of Chicago capitalists, and has taken over the Nightingale mine, south-east of Benton. The prospect has been thoroughly proved with drills and invites investment to make it a producer of both zinc and lead ore. A two-compartment shaft will be sunk at once but mill construction will not be begun until the extent of the orebody is determined.

CUBA CITY.—At a meeting of the stockholders of the Connecting Link Mining Co. held under special call at Cuba City, September 15, an amendment was voted to the charter increasing the capital stock from \$100,000 to \$300,000. A new mill has just been put into commission on shaft No. 1, the second of this style and type to be installed. Extensive exploration work on new leaseholds recently acquired and further development and equipment are the reasons for increasing the capital stock. The Connecting Link produces both lead ore and zinc ore.

The Zinc Hill Mining Co. is following an active program in this district. A two-compartment capacity shaft is going down on the Susan Dean farm, to tap a lode of zinc ore proved by drilling, and mill work is under way. Drills on the Wm. Mueller farm are in the 57th boring. It is proposed to carry this work of exploration up to about 100 borings. The Mueller land shows extensive deposits of lead ore in the blue rock strata a feature uncommon in this field. It is claimed by those in charge of the work that one of the best lead mines known in the field will be developed as a consequence of these discoveries. Shipment of zinc ore is being made by the Zinc Hill Mining Co., from the Big Dick mine, at the rate of 3 to 5 cars per week. Lead ore is mined in quantity and new ground for lead-ore production is being opened up on the range north-west of the Big Dick mill.

BRITISH COLUMBIA

INCREASED FREIGHT-RATES INJURING CANADIAN MINING INDUSTRY.

VANCOUVER.—The Canadian Railway Commission has granted an increase of 35% in the railway freight-rates in British Columbia, and the change already has gone into effect. This will work great hardship to a number of mining properties, and in many instances will mean

that the ores must be concentrated before shipping to the smelter or the properties will have to close. It is not so harmful to the mines situated on the coast, because they probably will ship to the Tacoma smelter, and, having the advantage of water transportation for the whole distance, will not be affected seriously. The Granby Consolidated M. S. & P. Co., which has heretofore shipped its blister-copper by the Canadian Northern, has made arrangements with the Canadian Dollar Shipping Co. to ship its blister by the Panama Canal.

Accounts concerning the Mayo district, the new silver camp near Dawson, are being received from miners and prospectors who are coming south for the winter. They say that Mayo City, 150 miles south-east of Dawson, on the Stewart river, bids fair to become a 'city of tents' because of the rush to that point of miners intent on

gang of men has been working recently on the property of the Fish Creek Mining Co., situated on the Alaska side of the boundary; a 4-ft. vein of galena has been uncovered. Work on the Silver Tip, Salmon River, has been closed down for the winter. The owners have had a considerable force engaged in stripping and preliminary surface operations; stringers of high-grade silver ore have been uncovered and it is planned to continue development next year.

James McKay and Charles Bibean have extended the option on their Lakeview property, at Glacier creek. Pat Welsh and associates, the optionees, have done a considerable amount of surface-stripping during the summer, and they felt that, although the result did not warrant them in taking up the option, it did warrant further exploration. Fitzgerald brothers have made arrange-

LAS DOS ESTRELLAS, EL ORO, MEXICO

making locations. The Guggenheim interests have taken in large quantities of supplies and are engaged in operations on Keno hill. They plan to take out 3000 tons of ore this winter. On Lookout mountain the Yukon Silver-Lead Co. is down 450 ft. on the vein with a large body of concentrating-ore in sight.

STEWART.—That the Salmon River section of the Portland Canal mining division in northern British Columbia has gone through its boom stage and there is now in progress much development that promises good results is the opinion credited to S. J. Schofield, who has returned after spending a summer at the head of a geological survey party in that region. The results of Dr. Schofield's researches will be published by the Canadian Department of Mines in the course of a few months. The Premier mine was the only property being worked at the time of Dr. Schofield's departure and on it a mill was being constructed to handle the low-grade ore. Shipments will be made during the winter; about 150 men are employed. The New Alaska property will be developed this winter. The group is situated in the Portland Canal district and the showing is good. A small

ments for the exploration of their property on the Alaskan side of the boundary with a diamond-drill.

TRAIL.—While drilling to what he believed would be a deposit of salt, J. A. Allen, of the University of Alberta, recently discovered a stratum of gypsum at a depth of 510 ft. The layer appeared to be of sufficient value to make commercial use practical.

PRINCE RUPERT.—While passing through this place a few days ago, H. S. Munroe, general manager for the Granby Consolidated Mining & Smelting Co., made the statement that the company is shipping 15 cars of copper per week. The output of Anyox will be increased, it was asserted, as soon as the price of the metal is high enough to make it profitable. The present low price has resulted in a policy of producing just sufficient to keep the plant in operation, the production being about 2,500,000 lb. per month. With better market conditions this could be increased without difficulty to 3,500,000 lb. per month. Referring to the Granby company's property, the Midas near Valdez Peninsula, Alaska, Mr. Munroe said that production would be commenced as soon as there was a stronger demand for the metal. The ore is

high-grade but will be concentrated before being shipped to the Tacoma smelter. He was reticent regarding the company's mining policy in the Boundary district, leaving the impression that not much could be expected while the copper market remained weak.

KASLO.—Working on No. 1 level of the Washington mine, near the Rambler-Cariboo, lessees recently shipped a carload of galena ore that they had taken out in three weeks. It averaged more than 150 oz. of silver per ton and 65% lead. At the same time lessees on the No. 3 level of the Rambler-Cariboo are said to be working in rich ore. A part of the Whitewater mine also is being worked under lease and it is authentically reported that the operators have shipped two carloads of ore from a newly uncovered orebody which has brought large returns. This work is near the Wellington mine, where No. 2 tunnel-level is being re-opened by the Standard Silver-Lead Mining Co. Labor conditions are improving in this district. The Payne mine, one of the first locations in the Slocan, is under bond and lease to a Seattle mining syndicate. A long lower cross-tunnel opens the property to a depth of 1500 ft., but little exploration of the vein at that level has been attempted. Above the fifth level the mine has been largely worked out, but below there is a large area that is expected to contain ore.

HOPE.—The re-opening of the Emancipation mine, near Hope, is assured. Equipment to the value of \$20,000 has been installed and it is expected that the first shipment of ore will be made next month. E. T. Hodge, the manager, states that the ore is high-grade, running as high as \$303 per ton. The vein is from 5 to 25 ft. wide and proved over the length of two claims.

ONTARIO

NEW DISCOVERIES AT THE PORCUPINE CROWN.

COBALT.—One of the most interesting pieces of exploration work ever undertaken in the Cobalt district, is now under way at the Crown Reserve mine. A diamond-drill hole is being put down 2000 ft. for the purpose of learning whether there is another diabase sill at that depth. One large diabase sill which passes through and over the Cobalt mines is believed by geologists to have been the source of the silver-bearing solutions which passed into the crevices and fractures of the adjoining conglomerates and Keewatin formation, creating the veins of silver ore. The veins have usually been found to extend not more than 1000 ft. from the diabase sill, and for that reason the deposits of silver ore are confined within definite limits. While excavating for the foundation of a rock-crusher at the old dump on the Kerr Lake mine, a narrow vein has been found, measuring less than one inch wide and consisting of calcite containing smaltite and silver. The vein is believed to be the one which was previously cut on the 90-ft. level, but which contained no silver at that depth. It lies beneath eight feet of sand overburden and will be opened from the surface. A silver discovery has been made in the Gillies Limit on the Cobalt-53 property, at a depth of 60 ft. In the narrow part of the vein there is high-grade silver ore and the prospects are

encouraging. Mining operations have been suspended on the White Reserve mine at Maple Mountain in the Elk Lake district, but exploration work will be done by diamond-drilling. A deal is being negotiated with English interests. A small steam-driven mining-plant has been erected on the Silver Bullion property at Leroy Lake, and sinking will be continued in an inclined shaft formerly put down 60 feet.

The Kerr Lake Mines, Ltd., has declared a dividend of 12½c. per share, payable October 15 to shareholders of record October 1. The disbursement will amount to \$90,000 and is the first to be made since the company made a capital reduction of \$1 per share on September 13 last year. Total dividends paid by this company now amount to \$9,780,000 since October 4, 1905.

PORCUPINE.—Labor conditions are beginning to show some improvement with the advance of the season. The men who went west as harvesters are gradually returning, and dullness of trade in some of the manufacturing centres of the United States has resulted in an influx of laborers from that quarter. There is still a shortage of about 2000 and production is thereby limited. The main shaft of the Hollinger Consolidated is being put down to the 2000-ft. level, and has now reached a depth of between 1600 and 1700 ft. The annual report of the McIntyre for the year ended June 30 shows a net profit of \$818,020, as compared with \$683,350 for the previous year. Operating-cost increased from \$825,998 to \$900,495. The quantity of ore treated was 188,835 tons of an average value of \$11.52 per ton, showing a considerable improvement over last year when the average value per ton was \$9.76. The total recovery of bullion was 99,461 oz. of gold and 21,140 oz. silver, valued at \$2,080,178, or \$11.02 per ton treated. The ore-reserves were estimated at 502,682 tons valued at \$5,595,500, as against 433,057 tons valued at \$4,777,324 last year. The exploration program of the North Crown on its Porcupine Crown property has resulted in a discovery which may be important to the entire Porcupine field. The diamond-drill has reached a depth of 2300 ft. and three other 1000-ft. holes will be put down. It is found that the greenstone formation tends to increase in extent, and indications point to the probability that much of the porphyry area found on the surface is underlaid with greenstone. The existence of this formation in proximity to the porphyry is specially favorable for gold deposits. Cross-cutting from the workings of the Porcupine Crown toward the Thompson-Krist property is actively progressing.

KIRKLAND LAKE.—The Orr, formerly the Kirkland Porphyry, has cut, on the 400-ft. level, what is thought to be the continuation of the Lake Shore No. 1 vein. It is 5 ft. wide and well mineralized. David Elliott has begun an action against the Orr Gold Mines, Ltd., and Hamilton B. Wills to set aside the issue of 800,000 shares of the company stock to Mr. Wills as a consideration for the transfer of certain mining shares, and to restrain Wills from dealing in the stock. The Lake Shore has begun sinking its shaft from 400 ft. to the 800-ft. level and will probably complete it by the end of the year.

THE INCREASE IN FREIGHT RATES

Salt Lake City.—More than a score of metal-mine operators from Nevada, Idaho, and California met with representatives of western railways in this city on September 22 and 23 to discuss freight rates. A. S. Edmunds, freight traffic-manager of the Salt Lake Route, presided at the meetings. The consensus of opinion among the mining men present was that unless some relief was granted from present high operating-costs, many low-grade properties in the West will be compelled to suspend operations. Utah mine operators were not active at the conference, as the State public utilities commission refused to permit the railways operating in Utah to increase freight charges on coal and ore shipments. A number of the mine operators present at the meeting submitted figures showing the effect of the increase of 25% in freight rates on their operating costs. Development of mines in Plumas county, California, will be greatly curtailed unless relief is granted was the assertion of representatives of various mines in that district. E. E. Paxton, of the Engels Copper Co., stated that his property is in the development stage and that \$2,500,000 had been expended to date on the mine. He furnished figures to the conference, showing the increases on mine supplies, such as steel, powder, flotation-oil, etc., which have resulted since the freight rate increase on August 26. Mr. Paxton further stated that the crude ore at the Engels property averages from 2.25 to 2.50% copper, with some silver; that a ten years' supply of ore is blocked out in the mine, with a much larger prospective supply. The Engels property is connected with the Western Pacific Railway by a railway 28 miles long, four-fifths of which is owned by the mining company and the remainder by the Western Pacific company. Mr. Paxton concluded his arguments with the statement that since the freight-rate increases on supplies and concentrates, operation of the property was a losing venture. A representative of the Franklin Mining Co., in the same district, stated that more than 20 mines in the development stage would be compelled to close unless relief is granted that will lower their operating costs. Officials of the Ward Leasing Co., near Ely, Nevada, stated that they have 200,000 tons of low-grade ore developed, averaging about 7% lead, 2 to 3 oz. silver, with an excess of iron; that a favorable smelting contract had been offered them, but that they would be unable to continue operations under present freight rates. Morton Webber, representing the Empire copper mine at Mackay, Idaho, stated that his company had a deficit since the first of the year of over \$40,000; that more than \$20,000 per year is paid by the company in freight charges, and that if the recent raise had been effective since January 1, the deficit would have been more than \$8000 additional.

Carson, Nevada.—The Nevada public service commission has denied the application of the railroads for a blanket increase in freight and passenger rates, a decision that is gratifying to the mining interests of the State. The decision declares the present rates to be 'discriminatory' and arraigns the railroads for the use of too-heavy equipment and consequent "failure to take advantage of economic methods of operation". The commission considered that "except as to coal, oil, and ore shipment, the reasonable, economical, all-the-year-round needs of traffic are best served by the use

of cars not in excess of 30 tons capacity". The mining interests were represented at the hearing by John G. Kirchen, S. Herbert Williams, and George R. Ryan.

Pioche, Nevada.—The San Pedro, Los Angeles & Salt Lake railroad will not advance the rate on ore valued at less than \$7.50 per ton and will haul ore of this grade from Pioche to Salt Lake City at the old rate of \$2.25 per ton. From 12,000 to 15,000 tons of ore is shipped monthly from the Pioche mines and the average profit is about 50c. per ton, which would have been wiped out had the railroad increased the rate.

CALIFORNIA

Amador County.—Webb Smith who has been superintendent of the Kennedy mine for 17 years is leaving. He will be succeeded by James Spear.

Engelmine.—The Engels Copper Mining Co. has commenced work for an impounding-basin on the land formerly known as the Stark ranch. A flume more than three miles long will be built to deliver the tailing to the basin.

Grass Valley.—The Idaho-Maryland is adding an electrically driven pump to its equipment in the Canyon shaft. It is portable and has a capacity of 350 gal. per minute. The Delhi Mining Co. is erecting a plant to use the available water-power. The bulk of the power generated will be sold to the P. G. & E. Co. George W. Root was elected president of the Alcalde Gold Mines Co.

Porterville.—The Porterville Magnesite Co. has announced that it will resume operations at full capacity.

San Francisco.—J. H. Massen is arranging to begin shipping fluorspar by motor-truck from his claims at Afton.

Sierra County.—Coarse gold with pieces worth a dollar or more is being recovered at the Table Rock mine. Twenty men are employed. The gold is in a layer of pipe-clay and its recovery is difficult. Sinking the 200-ft. shaft at the Kate Hardy is being continued in spite of the shortage of power although the mill is hung up on that account. The tailing at the Young America mine has been sold by J. Bonnali. Richard Phelan has bonded the Buttes Saddle and Sacred Mount quartz mines on the Sierra Buttes.

IDAHO

A flat increase of 60 to 75c. per ton in smelting charges on all ore received at the Bunker Hill smelter was announced by F. M. Smith, director of the Spokane office of the company. The increase will take effect at once. The action was taken following a general raise all over the country. "The increase in the cost of coke, coal, and all general supplies, because of the increase in freight-rates, is the reason for the raise," said Mr. Smith. "The exact amount which we will be compelled to assess the miners has not been determined, but it has been decided to make it a blanket increase on all ores. As near as I can state from observations the increase will be from 60 to 75c. per ton." Operations at the North Bunker Hill property in Wardner are progressing in a very satisfactory manner, according to reports. A cross-cut is now under way from the 500-ft. level of the main shaft, which is to be extended westward some 200 ft. to cut the vein exposed on the 500-ft. level. Good progress is being made with the work.

TEXAS

O'Donnell.—Although practically all the briny lakes and basins of this part of Texas have been under lease for potash development for more than a year nothing has been done yet toward actual production of potash. It is asserted that one reason for the delay in constructing potash-extracting plants is the fear that importation of the German product may be resumed and it would then be unprofitable to work the domestic deposits.

According to the reports of chemists who have tested the water and earth material of the different deposits of the south plains region of Texas they contain potash in great abundance and the average content is more than 12%.

The tentative plans of the lessee call for the construction of large plants at O'Donnell, Meadow, and Brownfield. It is said to be feasible to pipe the potash-laden water from the lakes to these railroad points.

MEXICO

Under date of September 13, a presidential decree was issued at Mexico City, extending to November 1, 1920, the time in which back taxes might be paid on mining claims which had fallen in arrears. This carries with it the proviso that taxes levied on the properties for the year 1920 shall be paid also on or before that date. What is said to be one of the most important mining deals in recent months was concluded in El Paso last week, when a local syndicate, composed of George A. Croff, Frank M. Kukli, R. H. Manning, and associates, took over the Bernice mine at Comidor, Chihuahua, having leased and bonded the property for a term of 25 years. The mine is in the Ventana mountains, an offshoot of the Pilaes, just across the Rio Grande from Presidio, Texas, and some 30 miles south of Valentine. The ore is in veins and deposits in limestone and carries lead and silver. One vein over 4 ft. wide outcrops boldly for over 900 metres along the top of the mountain. The ore is said to run 75% lead and carries a few ounces of silver, and according to assays will net, after paying hauling and freight expenses, between \$95 and \$100 per ton. The lessees are planning to begin operations at once and will drive a cross-cut 100-ft. adit from the eastern side of the hill that will cut the vein at a depth of 100 ft. The ore will be hauled to Valentine or to Chispa, on the G. H. & S. A. railroad for shipment to the El Paso smelter. Another important mining deal is reported to be under way farther down the Rio Grande on the Boca del Carmen property, a big lead-silver property on the Mexican side of the Rio Grande, 90 miles south of Marathon, Texas. In the Las Minas mountains east of the station of Ojo Caliente, a mine of silver-lead is being developed by a company of El Pasoans. The ore is said to be high-grade silver and lead. Conditions in Chihuahua are considered as good or better than at any time since the death of Madero.

Because of the clearer political atmosphere Greene-Cananea resumed dividends last month, paying 50c. per share. The mine strike at Cananea, Sonora, has been called off, according to a report made to Gov. Flavio A. Borquez at Nogales, Sonora, by a commission appointed by President de la Huerta to investigate threatened labor troubles in the Cananea district. The commissioners reported to Governor Borquez that the miners demanded more pay for less work. Their recommendation to President de la Huerta will be a compromise. The Moctezuma Copper Co. is making great improvements in its plants at Nacozari and Pilaes, Sonora. It has recently completed an addition to its power-house at Nacozari that will house four new Diesel engines. The concentrating-mill is being remodeled so as to get improved costs and increased efficiency. The capacity of the mill will be increased from 2000 tons to 3000 tons. At Pilaes, new blacksmith, tool-sharpening, and machine shops are being erected, as well as foundations and a building for new air-compressors.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. B. Lakenan is in San Francisco.

Morton Webber is at Salt Lake City.

Arthur DeW. Foote, of Grass Valley, is here.

J. W. Paul, of the U. S. Bureau of Mines, is in Utah.

Henry Krumb has returned to Salt Lake City from New York.

L. S. Cates has returned to Salt Lake City from Arizona and New Mexico.

W. O. Pray has moved from Des Moines, Iowa, to De Beque, Colorado.

H. B. Tooker, traffic manager for the Jackling companies, is at Salt Lake City.

Simon R. Guggenheim was at Pocatello, and is visiting several mines in Idaho.

A. J. Beaudette, of Seattle, is visiting San Francisco, on his way to South America.

Norman Carmichael, general manager for the Arizona Copper Co., is in New York.

Rudolf Gahl, of New York, is now with the Cerro de Pasco Copper Corporation, in Peru.

H. C. Carlisle, of the Nevada Wonder Co., at Tonopah, was in San Francisco last week.

D. M. Pattison, of Los Angeles, formerly manager of the Denn mine, is at Bisbee, Arizona.

A. W. Hahn, metallurgical engineer for the Metals Disintegrating Co. of New York, is in Utah.

T. M. Daulton, general manager for the Placer Gold Mines Co., of Atlin, British Columbia, is at Seattle.

W. A. Green has left Palo Alto to go to La Paz, Bolivia, where he will be with the Guggenheim Brothers.

Horace V. Winchell, on his return from Alaska, passed through San Francisco on his way to Oatman, Arizona.

Kirby Thomas, of New York, will be in Colorado several weeks engaged on examination work in the San Juan district.

Alliene Case has resigned as general superintendent of the Tonopah Extension mine, and is now living at Oakland, California.

Robert R. Pollok was in San Francisco on his way from Webb, Arizona, where he has been making an examination of vanadium deposits.

Charles R. Fettke, mining geologist with the Carnegie Institute of Technology, has been visiting mining and metallurgical centres in Utah.

E. M. Sawyer, manager of the Burro Mountain branch of the Phelps Dodge Corporation, at Tyrone, New Mexico, is spending a few weeks in California.

B. B. Nieding, formerly manager for the Carbon Hill Coal Co., at Carbonado, Washington, is now with the Kennecott Copper Corporation at Kennecott, Alaska.

Rienzi W. Macfarlane, assistant superintendent of the Longfellow division of the Arizona Copper Co. at Morenci, has been spending the past month near Parial, Mexico.

Lester E. Grant has been promoted to the managership of the Braden Copper Company, in succession to S. S. Sorensen, who goes to the New York office in a consulting capacity.

C. V. Jenkins, formerly business manager for the Nevada Con. Copper Co. at McGill, Nevada, and now connected with the New York office of the Jackling companies, is at Salt Lake City.

William R. Appleby, dean of the Minnesota State School of Mines, and **Edward W. Davis**, superintendent of the Mines Experiment Station at Minneapolis, are making a tour of Western mining districts.

Zinc-dust, cents per pound.....	12.50—13.00

EASTERN METAL MARKET

(By wire from New York)

September 27.—Copper is inactive and easy. Lead is quiet and lower. Zinc is dull and weak.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE WORLD'S STOCK OF GOLD

From its London information service the Bankers Trust Co. has just received the following interesting study of the world's gold situation:

The table shows the gold holdings of the world's State banks and Treasuries at the end of 1913, 1918, and 1919, and also at the end of June last, and therefore gives a measure of the movement of gold money during the War. It is necessary to include, at any rate, one doubtful item—that of the Imperial Bank of Russia, for which no figures later than that of October 1917 (\$129,500,000, or, at par, \$629,370,000) is available, and the totals shown since that date are approximations much open to question. The last two amounts of \$315,900,000 are based on the statement that the gold-reserve transferred to Omek amounted on August 1, 1919, to 651,532,118 rubles. If the figures set down for Russia are too high, they affect the calculations in this statement accordingly.

The table is not exhaustive, since Greece, Rumania, Brazil, Uruguay, Peru, the Straits Settlements, and the banks of issue of Scotland, Ireland, Victoria, and New Zealand are not included; but if these were added they would probably account for 270,000,000 (at par, \$340,200,000) at the end of 1913, rising to \$85,000,000 at the end of 1915, and thereafter probably falling somewhat.

The addition of these further banks, however, would not materially affect the total of the table. The figures include gold held abroad:

	Demand	3.51 1/4
Francs, cents:	Cable	6.76
	Demand	6.77
Lire, cents:	Cable	4.27
	Demand	1.75
Marks, cents:	Cable	1.75
	Demand	1.75

Eastern Metal Market

New York, September 22.

There is very little change in any of the markets, most of them being inactive. Prices have receded slightly in some cases.

The copper situation does not improve but values are unchanged.

The tin market continues quiet and easy.

Lead has declined further in the East, due to the import situation.

There has been very little alteration in the zinc market.

Antimony is unchanged.

IRON AND STEEL

Developments both inside and outside of the steel industry have encouraged buyers in their waiting attitude, says 'The Iron Age'. The tendency toward an easier market is more apparent. Output of pig-iron and of steel products is increasing and October promises to figure again as a month of records. Both in the Pittsburgh and Chicago districts the Steel Corporation has added to the number of its active blast-furnaces. At Chicago its steel-ingot output is 85% of capacity. The railroad situation shows continued improvement and stocks at mills have been cut down—those of the American Sheet & Tin Plate Co. by 50%.

Price changes are not well defined. While the general tendency is for the higher prices on finished products to approach those of the Steel Corporation, one or two changes in the other direction are reported.

An exception to the general run of cancellations from automobile makers appears in several calls from such companies in the past week for the shipment of strip steel they had held up. However, the week has brought further reports of reduced melt by foundries dependent on the automobile industry, also of the cancellation of machine tools ordered for motor-car work.

COPPER

The fact that the copper market does not improve, as was expected, is a cause of speculation by many. In fact the moderate revival of inquiry which appeared recently has not augmented but has fallen off. There is very little domestic buying and the exchange situation is such that foreign business, which has been fairly good, has received a check. The volume of the latter is put at around 20,000 tons per month for the next three months, as based on recent sales. In the absence of sustained demand of any proportions prices depend largely on the seller. Some of the leading producers of both Lake and electrolytic copper still maintain their quotation at 19c., New York, while others take some business at 18.75c. Small producers and dealers are doing a little business at 18.25 to 18.50c., delivered. The tone of the market is not as confident as recently; some producers are pessimistic and are expecting curtailment in output, while others are still predicting a buying movement soon. The London market was easier early this week.

TIN

While there was a moderate business done last week, on the whole the market continues dull and featureless. The transactions referred to were mostly with dealers and involved September-October shipment, or metal for arrival this year, at around 45.50c. The week on the New York Metal Exchange has been a quiet one, total sales, including yesterday, amounting to only about 75 tons. The feature of this was the continued sales of 25-ton lots under the hammer. Business of this character has been heavy in recent weeks. Most of this metal in the last three days went at 44.37½ to 44.50c. There is reported a better demand for 99% tin.

The weakness of the market on this side is explained as due to an abundance of spot Straits, which yesterday was quoted at 44c., New York, caused by heavy arrivals. Thus far this month the tin arrivals have been 3680 tons, of which only 285 tons is credited to Pacific ports. The quantity afloat is 4260 tons. The London market yesterday was down, with spot standard at £272 15c., future standard at £278, and spot Straits at £274 15s. There is also an ample supply of Straits tin in England and speculation is largely absent.

LEAD

The New York market is dull and there is little to say. General conditions have not changed and the situation is dominated by import metal, the arrivals being heavy. On Monday last week two steamers brought in 3500 tons. Demand is light but consumption continues very heavy. The imported metal has sold at 8c., New York, duty paid, which establishes the outside-market quotation, that of the Trust still standing at 8.50c., New York. No material change is expected soon and the weakness in exchange, which fell to \$3.47 yesterday, does not help the situation. The Western market is quiet and stable at the level of the leading interest, or 8.25c., St. Louis.

ZINC

The market is marking time and there has been very little change in values. The London and import market situations are dominating factors. So mixed is the situation in the East that it is difficult to quote values. A fair appraisal seems to be 7.80c., New York, for imported metal, with some domestic, possible re-sale, offered at 8.15c., New York. The St. Louis market is 7.75 to 7.85c., with demand now fallen to the hand-to-mouth order. The betterment in galvanizers' needs has fallen off again and was evidently only for temporary replenishment of stocks.

ANTIMONY

The market is inactive, with wholesale lots for early delivery quoted at 7.12½, New York, duty paid.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, are available at 34.90c. f.o.b. producer's plant, with foreign metal offered at 31 to 32c., New York.

ORES

Tungsten: The week has been a quiet one, though there has been some ore offered which did not result in buying. Quotations are practically unchanged and nominal at \$5 per unit up.

Ferro-tungsten is in quiet demand at 80c. to \$1.05 per pound of contained tungsten.

Molybdenum: Conditions are unchanged in a very dull market with quotations nominal around 70c. per pound of MoS₂ in regular concentrates.

Manganese: There is no demand. High-grade foreign ore is offered at around 65c. per unit, seaboard, but consumers appear unwilling to pay more than 55c. per unit and are probably amply supplied.

Manganese-Iron Alloys: There is very little demand for either ferro-manganese or spiegeleisen and prices are unchanged. Both British and American ferro-manganese are available on a basis of \$170, seaboard. There has been a sale of 500 tons at \$170, seaboard, for early delivery, and one of 300 tons of spiegeleisen at \$82.50, furnace. Aside from these, sales are confined to a few small lots and inquiry is very light.

Ferro-silicon: The market for 50% alloy is quiet at \$75 to \$85 per ton, delivered, while the electric 14 to 16% alloy is in fair demand at \$65 per ton.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

STEP INDUCTION REGULATOR FOR ELECTRIC FURNACE VOLTAGE CONTROL

For controlling the energy in-put for carborundum, graphite, aluminum, zinc, and similar types of electric furnaces, the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., is manufacturing a step-induction regulator which gives a uniform voltage over a wide range. The regulator consists of a furnace-transformer, an induction-regulator, switches, and push-button control. This apparatus utilizes the principle of varying the high-voltage tap on the transformer for controlling the energy-input to the furnace. The function of the induction-regulator is to vary

Step-Induction Regulator Complete with Transformer and Control-Panel

the voltage between taps. After the voltage of the adjacent tap is reached the selector and transfer-switches automatically transfer the induction-regulator so that it will function between the next two taps. One of the main features of this apparatus is that the entire voltage-range is controlled by two push-buttons, one for boosting and one for bucking the voltage.

The construction of the apparatus is as follows: On the shaft of the regulator is geared a selector-switch, the joints on this switch being connected directly to taps on the high-voltage winding of the furnace-transformer. The selector-switch arm moves from one contact to the next, automatically, as the induction regulator moves. The function of the feeder-voltage regulator is to add to or subtract from the normal voltage of a transformer-tap and is designed so that at the position of maximum boost it will add exactly one-half of the voltage between adjacent transformer-taps, while at position of maximum buck it will subtract exactly one-half the voltage between adjacent transformer-taps. Considering, then, a single position of the selector-switch arm, a single rotation of the moving coil of the induction-regulator will vary the voltage impressed on the high-tension winding from a position one-half step below to a position one-half step above the voltage point actually repre-

sented by the transformer-tap. The selector-switch arm is moved from one tap to the next just as the voltage one-half way between adjacent taps is reached, so that continued rotation of the regulator coil produces a continuous

Motor-Operated Regulator

variation, raising or lowering the voltage depending only on the direction in which the regulator coil is being turned.

While the above is the fundamental operation of the apparatus, in actual practice there are slight modifications. The moving coil of the regulator makes but one-half revolu-

Diagram of Connections

tion to go from the position of maximum buck to the position of maximum boost, at which latter point the selector-switch moves to the next higher voltage-tap, and the regulator must be brought at this point to maximum buck before it can, by continued operation, raise the voltage over another step. That is, at this point, the direction of current

through the regulator coil must be reversed. Actually, the result is obtained by a second coil of opposite polarity which is cut in at the proper time by a transfer switch and the regulator changes directly from maximum boost to maximum buck, so that continued rotation still acts to raise the voltage. The two-coil arrangement also makes desirable two-selector switches geared together for continuous variation of the voltage. With high incoming line-voltage a series-transformer is interposed between the high-tension line and the induction-regulator. This allows the use of a less bulky low-voltage induction-regulator, and ensures against trouble with insulating moving parts for high potentials. In this case, two coils are incorporated with the series-transformer instead of in the regulator itself, and accomplish the same current-reversing purposes. The operation of this regulator may be seen by references to the schematic diagram.

THE MERCO NORDSTROM PLUG VALVE

The taper plug-valve, when properly constructed, is undoubtedly the most efficient form of valve for universal use when it works. When, on the other hand, it sticks and binds in its seat, it becomes one of the most 'onery' pieces of mechanism that it is possible to imagine, and has probably spoiled the tempers of more good mechanics than any other one cause.

S. J. Nordstrom, a mechanical engineer engaged at Mexico City in the design, construction, and operation of cyanide

Phantom View of the Merco Nordstrom Valve

plants, was impressed with the obvious defects and shortcomings of valves in handling cyanide solutions and slime in the concentrating plants and mills of Mexican mining centres. Mr. Nordstrom saw that the difficulty with all forms of patent lubricated plug-valves was that, given a perfect fit between the valve and its seat, there was no possibility of forcing grease into a space which did not exist, namely, that there was no clearance between the valve and its seat. He saw then that it was necessary to design a valve in such a way that the lubricant itself could be used to lift the valve from its seat so as to allow clearance and a consequent spreading of the film of lubricant over the surface of the valve-seat. Having arrived at this conclusion, the present design of this valve soon worked itself out as a closed plug-cock with chamber at the bottom of the valve-seat, a receptacle for grease in the shank of the plug connected by drilled ducts with channels in the taper sides of the plug, which channels continued to the bottom of plug, thereby connecting with the chamber when the plug was seated in the valve.

References to the illustration will show clearly the working principles of this valve. The phantom-view showing the

plug exposed indicates the action of the grease. Considering that the grease-chamber at the bottom, the grease-channels, the grease-duct, and the cylindrical space underneath the end of the lubrication-screw are entirely filled with lubricant, and considering also a perfect fit between the plug and its seat, it is evident that a slight turn of the lubrication-screw will exert a tremendous hydraulic pressure upward on the bottom of the valve-plug. It will be noted that the cap which is held down by bolts at either side (not shown in the illustration) forms a tight joint through an elastic packing washer. The valve-plug is so machined that when seated in the valve its faced shoulder is slightly lower than the facing on the edge of the valve-cage. When, therefore, the cap is clamped down tightly, it makes first a tight joint on the edge of the valve cage and the elastic packing is lightly pressed against the anti-friction washer on top of the plug facing, leaving sufficient elasticity in the packing so that the hydraulic pressure mentioned above raises the plug by an infinitesimal (but sufficient) amount to allow clearance for a film of grease between the plug and the seat. It is in this hydraulic lifting action that this valve is differentiated from all other lubricating plug-valves, and it is right here that its success lies.

Iron valves of this type have been tried out in a sal-ammoniac solution, closed for two months so that they were practically rusted solid, and one turn of the lubrication screw was sufficient to allow very easy turning of the plug. A ninety degree stop is arranged between the shank of the plug and the valve cap, and this stop has an extension above the valve cap so that the operator can see at a glance just how the valve should be turned and when it is open and shut. This stop is so positioned that the grease channels on the sides of the plug can never be open to the action of the liquid which is being handled. The Merrill Co., which is distributing this device, expects that it will be found especially useful in handling cyanide-solutions and in marine work.

COMMERCIAL PARAGRAPHS

The Main Belting Co., manufacturers of 'Leviathan' and 'Anaconda' belting, are issuing 'Conveyor Problems and their Solution', which they describe as "a practical consideration of accepted conveying-practice as developed by engineers of authority, illustrated by notable examples of scientific belt-conveying". The illustrations are good and the examples of typical arrangement are plentiful. The booklet should be both interesting and useful to those who have conveyor problems requiring solution.

Ruggles-Coles Engineering Co., of 50 Church street, New York, announces the temporary discontinuance of its Chicago office, formerly at 332 South Michigan avenue. All inquiries, orders, and other communications previously directed to that branch will be attended to by the New York office. It also announces the opening of new sales offices in the Newhouse building, Salt Lake City, Utah, and in the Old National Bank building, Spokane, Washington, where inquiries and requests for information will be given prompt attention.

Oliver Continuous Filter Co., manufacturer of the Oliver continuous filter, dry vacuum pumps, air-compressors, etc., has appointed J. F. Mitchell-Roberts as its special representative to better serve its constantly increasing clientele in England and Europe. Offices have been established at No. 2 Broad Street Place, London, E. C., 2, England. In connection with its offices at 33 West 42nd street, New York, and 503 Market street, San Francisco, California, this company maintains laboratories for investigation of filtration problems, and similar arrangements will be made at its new London office.

Like Mahomet and the Mountain

IT was lots easier to bring Prest-O-Lite and the oxy-acetylene flame to this mammoth wheel than to haul the wheel five miles from a mountain mine to a repair shop.

That's one of the advantages of Prest-O-Lite. Its ready portability makes oxy-acetylene welding possible and remarkably economical *anywhere* and *everywhere*.

And a chain of forty plants and warehouses assure a constant supply of Prest-O-Lite, the Universal Gas with the Universal Service.

All of which means a Nation-Wide Service which you will be interested in knowing all about.

THE PREST-O-LITE COMPANY, Inc.

General Offices, Carbide & Carbon Bldg., 30 E. 42nd St., New York City

KOHL BUILDING, SAN FRANCISCO

TORONTO

T. A. RICKARD, . . . Editor

NINE HUNDRED miners, it is reported, are coming to the United States from Spain. They represent the orderly element among the men on strike at Rio Tinto, as described in these columns on September 4. Incidentally, we note that the Rio Tinto company has passed its dividend.

CLAIMS aggregating \$5,826,655 have been decided by the War Minerals Relief Commission; on these 31.64%, or \$1,843,887, has been allowed. As 994 claims have been decided and 769 have been rejected, there can not be more than 200 remaining for consideration by the Commission. We have heard of only one claim, from Alaska, that has been paid in full.

THE 23rd annual convention of the American Mining Congress, at Denver, during the week beginning November 15, will be signalized by a conference on the standardization of mining machinery, equipment, and labor-saving devices. Other subjects to be discussed will be taxation, the McFadden Bill, War Minerals Relief Commission, the petroleum industry, and the commercial and legal phases of the flotation process.

QUESTIONS concerning assessment work are becoming frequent as the end of the year approaches. Miners want to know whether they still can take advantage of the abatements allowed during the War. The answer is in the negative. All the joint resolutions relieving the owners of mining locations from doing assessment work as heretofore required by law are now ineffective. There is only one possible exception and that is the joint resolution approved by the President on July 17, 1917, whereby officers and enlisted men in the service were relieved of the obligation to do assessment work on their claims for a period of six months after being mustered out of the Army or Navy.

APROPOS of the interesting article in this issue by Mr. A. B. Parsons, it may be mentioned that at some mines concrete is believed to be the only kind of support capable of holding heavy ground. For example, a portion of the Snake Creek tunnel, in the Park City district, which will ultimately connect with the shaft of the Judge mine at a point 5000 feet from the portal, is lined with concrete. The cross-section is egg-shaped and the reinforcement is carefully designed to assume the tensional strains, while the compression is provided for by the con-

crete. The arch of the adit is only one-third as wide as the Butte & Superior station, but, of course, the character of the ground in the two localities is different.

REFERENCE to new methods of flotation, more particularly patented discoveries that do not involve the use of oil, are frequent in the daily and semi-technical press. Such announcements, not unnaturally, are accompanied by the pious hope that the non-use of oil will permit the owners of mines to escape the impositions and exactions of the Minerals Separation people. This is too optimistic. Besides patent No. 835,120, which covers the use of less than 1% of oil, the Minerals Separation company owns patent No. 962,678, covering the use of a soluble frothing-agent, which is one of the points involved in the Miami lawsuit. It may be possible to find a frothing-agent that is not soluble, but it is difficult to conceive of any way of modifying the surface-tension of water by means of an insoluble substance. Of course, everything in nature under special conditions is more or less soluble in water; that exemplifies one of the iniquities of the patent system, under which claims of a perfectly absurd comprehensiveness are granted without any appreciation of their meaning.

RICH ORE has been found at Ely under exceptionally interesting conditions. A reference to the discovery was made last August in the 'Boston News Bureau', which quoted Mr. Louis Ross, a mining engineer of distinction. The Boston paper exaggerated the dimensions of the orebody and thereby threw doubt upon the accuracy of the news. A local paper, the 'Ely Times', published a brief article on the subject, and we made mention of it in our news columns two weeks ago. As a matter of fact, we learn the discovery is both important and significant. During the latter part of July, while the 700-foot level in the Ruth mine, of the Nevada Consolidated, was being driven from the Star Pointer shaft, a high-grade mass of sulphide ore was cut. The first assay showed 8% copper, but after about 70 feet of advancement the assays improved to 13%. This ore is in the lime-shale, near the contact with the monzonite-porphry; it is at a horizon below the zone of secondary enrichment marked by the disseminated chalcocite; it appears to be an enrichment of the primary chalcopyrite. It is ore rich enough to be smelted without previous concentration in a mill. No estimates of tonnage are available, but we are

informed that the work so far done has exposed a large body of rich ore. The event is encouraging to the so-called porphyry copper group, for it points at the possibility of bonanzas being found even in mines characterized by enormous tonnages of a uniformly low-grade ore.

AT the recent congress of the European Socialists belonging to the so-called Second International, at Geneva, a revision was made of the definition of the term 'Labor'. It was declared by the Congress that it included not only the manual working wage-earners, but also intellectual workers, independent handicraftsmen and peasants, and "all those who personally co-operate in the production of utilities of any sort". Therefore the term excludes, it is declared, "among healthy adults, only those who idly live by owning". The French call them '*rentiers*'; we call them the 'idle rich', who toil not neither do they spin. The British Labor party, two years ago, adopted the phrase "workers by hand or by brain", and we prefer it to the Genevan definition. In any event, we are glad to be included in the category of the workers. It is about time that the manual laborer understood that the work of the world is done by many kinds of men, and that the best work is that which is most intelligent.

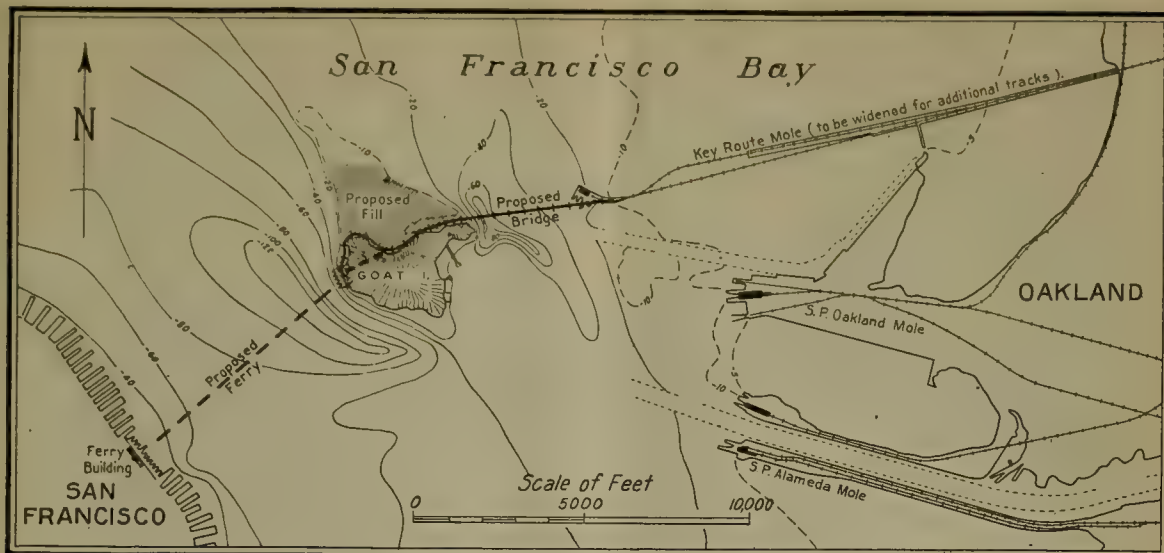

SHORTAGE of the right kind of men, presumably, has led the Canadian Geological Survey to engage women. Two lady geologists are reported to be in the field. They ought to be able to collect all the information necessary for a useful report; indeed, they are said to carry a gun and a revolver as part of their outfit, so that if anybody is slow in coming forward with the necessary data they will be in a position to exercise persuasive powers of more than usual feminine effectiveness. We shall expect sundry distinctive touches in the writings of these ladies, and the introduction of new descriptive terms. For instance, they are likely to find pleats in the shale, rucking in the rhyolite, and tucks in the trachyte. Stranger things have happened. The 'selvage' of a vein is akin to the 'self-edge' of a piece of cloth. 'Seams' came into mining by grace of the seamstress. Joking apart, geologizing by women is no new thing. The oldest Geological Society, namely the one in England founded by Lyell and Murchison, includes a considerable number of the gentler sex. Many of them have contributed valuable articles to the proceedings. Geology used to be considered a polite study, it was one that was untainted by commercialism, it appealed to gentlemen and ladies, that is, to amateurs. And that is why the geology of the Victorian period in England contributed so little to the aid of mining. The geologists of both sexes looked askance at any phase of their subject that touched on money-making. They delved in fossils, they delighted in glacial drift, they enthused over stratigraphic difficulties. All that is changed, and the ladies too. Undoubtedly the new recruits to the Canadian Survey will have an eye to the economics of their subject; they will be in sympathy with the miner, and they will collect the data helpful to him in his search for metals. We welcome them with the grave courtesy suitable to the occasion. There is plenty of work for

men to do; many of them are doing the work that women can do; it is well that there should be a proper distribution of talent and energy into suitable channels.

THE average American who thinks he is fairly familiar with the geography of his own country may find that some of his ideas regarding locality are gained from impression rather than from precise observation. For instance, a good many may be surprised to realize that the Island of Cuba if transposed directly north would extend from New York City to central Indiana; and that the town of Nome in Alaska is farther west than Honolulu. Some will even be mildly astonished to learn that part of Minnesota is more than 100 miles farther north than the uppermost end of Maine, and that San Diego is farther east than Spokane, in eastern Washington. The explanation is that the meridians and parallels of latitude on most of our maps are curved lines, whereas we unconsciously imagine a set of rectilinear co-ordinates. The Geological Survey recently has compiled numerous data regarding the extent and area of the United States. The extreme north and south dimension is 1598 miles, which is the distance from the southernmost part of Texas due north to the Canadian border; the maximum breadth is 2807 miles, from West Quoddy Head near Eastport, Maine, to the Pacific. The shortest distance from the Atlantic to the Pacific is between points near Charleston and San Diego, a distance of 2152 miles. The length of the Atlantic coastline is more than twice that of the Pacific, but this is, of course, due to the configuration of our eastern shores. This does not, however, include the Gulf of Mexico, which itself borders the United States for 3640 miles as compared with 2730 miles touching the Pacific and 5560 the Atlantic. The gross area of the United States is 3,026,789 square miles, of which 2,973,744 is land and 53,015 is occupied by rivers and lakes, exclusive of the portion of the Great Lakes that is included in our territory.

Crossing the Bay

During the past week the old problem of improving transportation across the Bay of San Francisco has been brought again into public notice by sundry suggestions proffered by Rear-Admiral Joseph L. Jayne, who has just retired as commandant of the Twelfth Naval District, which includes the station at Mare Island, near San Francisco. The subject is one of more than local interest; San Francisco is the chief port of entry on the Pacific coast of North America; it is a gateway on the main line of travel to the Orient; it is one of the most interesting cities in the world and is situated on a bay famous for its beauty. Every mining engineer has been here or hopes to come here some day. We need not apologize for discussing an engineering project the purpose of which is to facilitate passenger traffic between the mainland and the peninsula at the northern end of which San Francisco stands, "the warder of two continents". The metropolis of California has a population of 508,000; on the opposite shore are the towns of Alameda, Oakland,

SKETCH SHOWING ADMIRAL JAYNE'S PROPOSAL

and Berkeley with a total population of 300,000. The trans-bay cities, as they are called, are the bedrooms of San Francisco; most of their inhabitants come to San Francisco to do their business. About 50,000 persons cross the bay daily. These include others besides 'commuters', for the transcontinental railways have their termini in Oakland. The chief problem is the handling of the purely local traffic, more particularly in the morning and evening. At the present time the crossing is effected by means of three ferry systems, linking the suburban electric-railway terminals with the wharves that extend beside the Ferry building at the foot of Market street, which is the main artery of San Francisco. The distance across the water is three miles and it is crossed in 17 to 20 minutes. During the rush hours the ferryboats are crowded; at other times there is an unnecessary duplication of service; moreover, automobiles are transported only by one slow, expensive, and indirect ferry system, by way of the Oakland estuary, so that motor traffic is subject to many unpleasant delays and exactions.

Admiral Jayne's proposal, briefly, is this: To erect a steel trestle from the end of the Key Route pier to Goat island, the real name of which is Yerba Buena. This trestle is to be high enough to allow the passage of small vessels. The island is to be pierced by a tunnel through which trains will pass to a site to be graded on the western side, where a union station will be placed. This terminal will have facilities ample for the transcontinental railroads as well as the suburban cars. Docks will be built here, and from them the ferries will ply to the San Francisco landing, only a mile and a quarter distant, as against the present ferriage of three miles. The island is the property of the Federal government; as early as 1869 the Southern Pacific Railway company tried to obtain the use of it for a terminus, but the railroad company at that time was so associated with predatory politics that strong opposition was offered to the proposal. To allow

the island to be used by a number of traction companies, and for the general benefit of the community, is quite another matter. We give a sketch showing the local topography, including soundings, which are important. It will be noted that a shoal extends as far as the present Key Route terminus, which is separated from the island by a narrow stretch of deep water. On the western side the water is also fairly deep, shoaling in the approach to San Francisco, the eastern part of which, as far as Montgomery street, is built upon a fill. How this system of transportation will be completed is another question. A tunnel of the tube type would be impracticable on account of the contour of the bottom. Various plans for a bridge have been proposed. In 1914 Mr. Charles E. Fowler suggested a cantilever structure from Goat island to Telegraph hill in three main spans of 2000 feet each, with a clearance of 150 feet at high tide. He estimated the cost at \$75,000,000. He proposed a cantilever bridge on the eastern side of the island, as Admiral Jayne does, connecting with a causeway. Six years ago it was estimated that 60,000,000 passengers would cross the Bay in 1925 at a cost of 5 cents; today 43,000,000 passengers are crossing annually at a cost of 9 cents apiece per trip, this being half the total cost of the journey from the suburban cities to San Francisco. Commuters pay \$4.80 per month. The toll has undergone a series of increases from the 5 cents levied, for ferriage only, before the War, when commuters paid \$3 per month. In 1916 a bridge 30,200 feet long, from Oakland to San Francisco, was proposed by Mr. Wilbur J. Watson, at a cost of \$25,000,000. A double-tube tunnel from the Oakland mole of the Southern Pacific to the Ferry building in San Francisco was estimated by Mr. Taggart Aston to cost \$15,000,000. The top of this tunnel was to be 45 feet below low water; it was to be 15,480 feet long, to which was added 11,370 feet for the approaches. It would take, it was estimated, only 20

months to construct, and would be less subject to damage by earthquakes than a bridge; but it includes no provision for motor traffic. This is becoming an increasingly important factor. It might be solved by carrying the cars on electric 'mules', or trucks, through the tunnel; but this would be much less pleasant than a bridge-crossing. No project can be undertaken without the concurrence of the Federal government, through the War Department, which exercises control over harbors. The interference with the tidal currents must be considered; also the effect of seismic disturbance. The Admiral's scheme is estimated to entail an expenditure of about \$15,000,000. It should include an enlargement of the causeway to the island, so as to provide for motor traffic. The tunnel through the island proposed by the Admiral is unnecessary, the shoal at the northern end of the island affording obvious opportunity for a fill ample for the purpose of a terminal station and docks. Any increase in the number of ferry-boats on such a short run as the mile separating the island from the City would augment the danger of collision, and for that reason among others it would be desirable to use large boats rather than the small ones, especially on the Key Route service, now running. In that event three or four vessels might suffice, if they made the journey in ten minutes, as seems likely. Thus ten minutes would be saved, besides the present duplication of service, creating an expense that is being passed, naturally, to the passengers. Whatever plan be adopted, the automobile traffic must be considered. At present the toll on automobiles is \$1.22 per crossing, or \$2.44 for the round trip, to which the passenger rate of 8 cents per person must be added. This is excessive, but the worst feature is the loss of time; the crossing from Oakland takes 45 minutes and the inadequacy of the space on the boats causes long waits, especially on holidays. In all schemes of inter-urban traffic nowadays it is necessary to make provision for automobiles. In California there is an average of one motor-car per seven persons. The suggestions made by Admiral Jayne have been received most favorably by the various municipal authorities and it is to be hoped that they will co-operate for the purpose of a consummation.

Industrial Relations

In a recent issue we discussed the book on 'The Great Steel Strike', written by William Z. Foster, who was largely responsible for that industrial conflict. We have received a reprint of an article by Mr. Charles Piez on the same subject. Mr. Piez was Director General of the Emergency Fleet Corporation during the War and proved himself a man of high character and remarkable ability; he is now president of the Link-Belt Company. He criticizes the report of the commission appointed by the Interchurch World Movement and says, quite fairly, that the members of that commission made a fundamental mistake in assuming or concluding that the strike "was waged wholly in the cause of hours, wages, and control of jobs, and over the manner in which all these matters were determined". On the contrary, he insists, and we

agree with him, that "the steel strike was but one of a series of broad industrial disturbances that were deliberately designed to wrest the control of industry from its owners, and place it in the hands of the radical element of organized labor". The statements made by Foster in his book prove this inference unmistakably; to him "the wage system is the most brazen and gigantic robbery ever perpetrated since the world began". Mr. Piez refers to the strike of the shipyard workers in January 1919 and describes the conditions under which it was started; how the men broke their agreement with the Emergency Fleet Corporation, which was a war-time Government agency; no question of hours or of working conditions was involved; the aim of the leaders, mostly aliens, was to secure the control of industry in the Puget Sound district, just as Foster and Fitzpatrick started the steel strike in order to attack the 'open shop', and to aggrandize themselves personally. We have to part company with Mr. Piez when he compliments Judge Gary. He says: "We have had many examples in the past two years of the effects of unlimited power in the hands of arbitrary, unwise, and selfish leadership". This, it seems to us, describes Mr. Gary as well as Mr. Foster. If labor and capital are to be reasonable in their demands, if they are to show a just appreciation of each other's rights and privileges, it will hardly be under the leadership of such opposing chieftains. We come back to the side of Mr. Piez when he animadverts upon the breaking of agreements made by the unions and the too frequent exhibition of a bolshevik contempt upon their part for the sanctity of contractual relations. If collective bargaining is to be honored in observance, it must be by a scrupulous recognition of the obligations incurred on both sides. An employer places his property in jeopardy when he dishonors his written word; it is not fair that the employee collectively should be able to ignore his own obligation with impunity. Indeed, the failure 'to play the game', to give a square deal, is at the bottom of most of our industrial troubles. When a man accepts a job at a given wage he tacitly engages to perform the day's work, and the honest workman does it; but the union, or the agitator who tries to control the union, discourages the idea of carrying out the implied agreement, encouraging the slacker, with the idea of decreasing the amount of work done for the wage, thereby thinking to leave more work to be done by others. This is as dishonest as getting ten hours work from a man for eight hours pay. In these matters fairness and honesty go hand in hand. Arbitrary action on either side is out of date. The public will support no side that deals unfairly, but unfortunately the public is rarely well informed, and therefore is unable to react until too late. The problem that faces the thoughtful student of economics, as Mr. Piez says, is "to appreciate the relative value of the three factors in industry, namely, capital, labor, and management, and to find a way of determining the compensation due to each". Obviously the community ought to compensate generously, in money and in honor, the men by whose humane and intelligent management the proponents of capital and labor can be brought into friendly harmony and joint efficiency.

THE BUTTE & SUPERIOR MINE, AT BUTTE, MONTANA

Mining Methods at the Butte & Superior

By A. B. PARSONS

This article will describe the methods of mining wide veins of rich zinc-lead-silver ore in heavy swelling ground, and sundry other features of the underground operations of the Butte & Superior Mining Co. in its mines at Butte. The Black Rock, as it is known locally because of the weathered outcrops of quartz-monzonite, is the most northerly of the productive mines in the district; in fact, it is situated beyond the line that was thought less than fifteen years ago to mark the limit of possible ore deposition; a belief on which certain well-known geologists were prepared to stake their professional reputations. However, in spite of the theory then prevailing, Capt. A. B. Wolvin in 1906 persisted in sinking on a rather hungry-looking lode with the hope of developing a copper mine. In this he was disappointed; but he did open a good vein of zinc ore. Like most mines that have become big producers, the Black Rock had its ups and downs until Capt. Wolvin sold the property and the present corporation was organized to work it in 1910. After a series of tests in an old mill at Basin, 20 miles south, on the Great Northern railroad, a concentrating plant at the mine was completed and production on a reasonably large scale was commenced in the summer of 1912. The market for zinc at that time was dull and not until toward the end of 1914 did prices advance sufficiently to stimulate output. During 1915-'16-'17-'18 operations were fully extended. So urgent was the demand

for production that some of the mining was hardly in accord with the best practice, although it was entirely justified by the condition of the zinc market. The miners and foremen, as a matter of course, followed closely the local practice that had been developed during 25 years of mining the copper ore in the district, and while it was recognized that the procedure was not always best adapted to the conditions it was also understood that any departure therefrom would be attended by disruption of the plan of operations. However, beginning with 1919 much attention has been devoted to establishing a more efficient system of mining and methods conducive to greater economy.

The Rainbow lode, which is the source of the bulk of the ore, varies in width and grade; in places it is divided into distinct branches by numerous faults, so that individual stopes vary in breadth from a single set to as much as 15 sets, that is, from 6 to 110 ft. While there is a general dip to the south, the irregularities are such that the ore-shoots are virtually perpendicular in so far as mining operations are concerned. The dip has changed materially in depth and shoots that were in No. 1 shaft at 1300 ft. are found near No. 2 on the 2200-ft. level. See Fig. 1.

There are now three vertical shafts. No. 1, the oldest, bottoms in a sump just below the 2050-ft. level; it has four compartments, two for hoisting ore and handling

the regular work, one for the cage of the 'chippy', or auxiliary hoist, and a fourth that serves as a manway and contains pipes, electric-cables, and ladders. Work on this shaft progressed steadily after 1907; it reached 1920 ft. in 1915, being in ore from the 1300 to the bottom level. It was through this shaft that all the ore was hoisted during the active years, 1915 and 1916, the largest output for a single month, 55,000 tons, having been recorded before either of the other shafts came into use. In the latter part of 1915 two new shafts were started at points indicated on the accompanying map of the 1600-ft. level, Fig. 1, about 60 ft. apart and some 500 ft. from No. 1 shaft. They were sunk vertically on what may be considered the hanging-wall side of the Rainbow lode, and in ground that was expected to be strong. Proximity to the new coarse-crushing plant of the mill was one consideration in selecting the site for the new shafts; facility in the distribution of supplies was another.

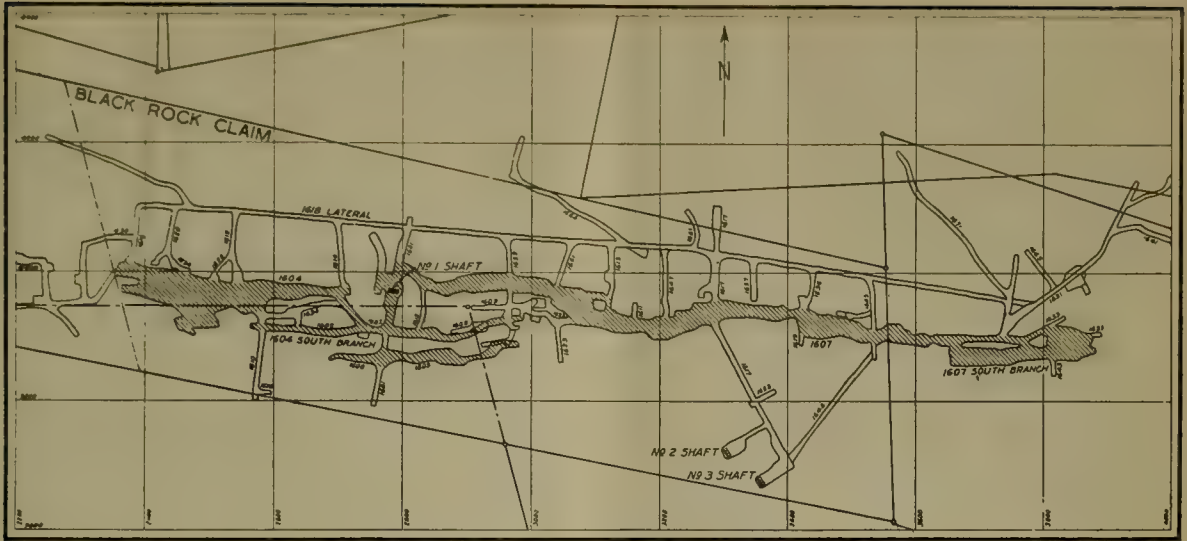

Both shafts have three compartments, including two for hoisting, and a manway. No. 2 is the largest, the main compartment measuring 17 ft. 1 in. by 7 ft. over all, as compared with 15 ft. 1 in. by 7 ft. for No. 3. No. 1 shaft has three hoisting compartments each 4 by 5 ft. Much of the work, in both of the new shafts, was done by raising from levels already established. At the present time No. 2 shaft has been driven to the 2300-ft. level; which is 300 ft. below the present sump of No. 3, to which a connection will be made by cross-cutting and raising. This procedure will reduce to the minimum any delay in current operation through No. 3, which is now the main working-shaft. No. 2 shaft has no skip-chutes and accordingly is not used for hoisting ore, all of this work having been done through No. 3 since 1917. Men and timbers are carried through No. 2; waste is transferred between levels; the main electric cables, air-lines, fresh-water lines, and the pump-column from the principal underground pumping-station occupy the third compartment. This shaft is up-cast and is equipped with a carefully designed system of fire-protection, including automatic sprinkler-heads.

Unfortunately, the ground penetrated by No. 2 shaft was not so good as had been hoped and a great deal of repair work has been necessary to maintain it in operating condition. Even at a distance of 50 or 60 ft. from the vein the ground, which is composed of soft granite, is blocky and slakes readily on exposure to the air. It is continually subject to movement. To facilitate the work of maintenance the worst places in the shaft have been protected with jacket or easing sets, following out the plan adopted in No. 1, where several hundred feet have been timbered in this way. The purpose is to enable necessary alterations to accommodate the changing ground, without disturbing the inner timbers. The method is not a new one, but the need for it emphasizes the exceptionally difficult ground that characterizes all the Butte & Superior workings.

The standard shaft-timbering prior to 1917 had always been regular rectangular sets, with wall and end-plates of 12 by 12-in. timbers, and dividers of 8 by 12-in. material. These were spaced at four or five-foot centres, and lagged

with two-inch and three-inch plank. In an effort to decrease the excessive cost for repairs and maintenance, considerable study was given to the question of developing a better method of shaft-timbering. The plan used in the last 450 ft. of No. 2 shaft has proved so satisfactory that the same method will be employed in the further extension of both the new shafts. It is similar to the cribbed timbering used in the old Comstock mines. This cribbing is of 12 by 12-in. timbers with a half-joint at the corners; the timbers are laid skin-to-skin, but are not drifted together. The result is a solid casing of 12-in. material with the necessary dividers between compartments. The comparative first cost is slightly in favor of the old method as against the cribbed sets; the regular timbering requires less material than the skin-to-skin methods but more work in the framing-shop; the hangers are expensive, whereas the item of labor for doing the actual timbering underground is approximately the same either way. When each layer has been thoroughly blocked against the walls there is practically no chance for local movement in the rock, and the collective strength of the entire structure is sufficient to withstand unusual pressure even on considerable lengths of shaft. By filling behind the timbers, the bad effects of slaking ground are largely obviated. Continual repairs due to broken lagging are avoided, and cracked end-plates or wall-plates are improbable, since any strain is distributed over a considerable number of large timbers. A shaft of this kind has most of the good features of one lined with concrete, and in exceptionally bad ground there is the added advantage of affording an extra degree of elasticity.

This last point has been illustrated in the timbering of stations as well as in the constructing of fire-doors and bulkheads at various points throughout the mine. The accompanying drawing, Fig. 2, shows two methods used for timber support at the regular shaft-stations. The usual excavation is 18 ft. wide by 14 ft. high in the centre; it runs back from the shaft for six or seven sets, spaced with 5-ft. centres, if the timbering is done as shown in the right-hand sketch. This trussed-set construction is the old standard station-set used largely in the Butte mines. The principal members are all of 12 by 12-in. material with 5-in. lagging on top of double caps, and 5-in. flooring as shown. This type of station did not prove satisfactory in the Black Rock mine. Not only were the double caps unable to withstand the excessive weight, but swelling of the ground frequently caused the floor to buckle to such an extent that expensive repairs became necessary, particularly where there was no skip-chute beneath the floor. The left-hand sketch shows part of a station timbered according to a design developed upon the same theory as that applying to the cribbed shaft-timbering. A number of such stations have been constructed, with excellent results, where there is no reason to believe that the conditions are less severe. Apparently, the skin-to-skin arch-type has proved its superiority over the other in bad ground. There was one particularly doubtful station on the 1200-ft. level at No. 2 shaft, where, as an experiment, a circular arch of solid concrete was built surmounting concrete walls. Forms were con-

structed and concrete to a thickness, in places, of 5 ft. was 'shot' into position with a large-sized cement-gun. The walls and arch practically formed a well reinforced monolith, tight against the rock of the excavation. Only a few months later a large crack developed running the full length of the station near the top of the arch. Later other cracks started and a large section was about to fall in when measures were taken to support the concrete with timber. Whether the six-member timber-arch construction would have given better service at this particular place is, of course, uncertain, but the chances are in its favor. This illustrates the point that the extreme rigidity of concrete may easily prove disadvantageous when subjected to underground conditions. It is interesting to note that most of the companies in the Lake Superior copper region are abandoning the use of concrete for supporting the workings after spending hundreds of thousands of dollars in an effort to use it successfully. The

experience there has been that the shifting ground causes the concrete to crack and crumble, thereby becoming not only useless but dangerous. The valuable feature that concrete is fireproof is largely offset by the use of gunite applied with the smaller cement-gun, which will be described later.

As stated before, there are skip-chutes at each of the stations at No. 1 shaft, and at those below the 1200-ft. level of No. 3. These vary in size from an actual working capacity of less than 100 tons up to 150 tons. The regular chute has no unusual features. The front is one set behind the timbers of the shaft and is lined with 4-in. plank faced with steel plates half an inch thick. The sloping bottom is of similar construction, whereas the timbered sides are 'bricked' with 12 by 12-in. square blocks, cut two feet long and placed so that the ends rather than the sides get the wear. The station-floor rests on 12 by 12-in. timbers spanning the chute, and the gates

FIG. 2. PRESENT (A) AND FORMER (B) TYPES OF TIMBERING

are operated by compressed air. The labor charged to the construction of one such chute, including miners, timber-men, mechanics, and miscellaneous, amounted to 900 shifts. The chute at No. 3 station on the 1900-ft. level is of special construction. On account of the blocky ground it was built of solid reinforced concrete, the stresses here being somewhat different from those required in supporting ground. Active development work was in progress on the 1900-ft. level at this time (early in 1919) and it was essential that the chute be constructed so as to interfere as little as possible with these operations. Accordingly, a false floor was put in at the station and the rock was broken from below until the bottom of the chute in the middle had been reached. This excavation was timbered to afford a new support for the station-floor, while space was cut at the sides for the walls of the chute. Old rail, pipe, and cables were used for reinforcement and the concrete for these walls was poured and allowed to set, after which they again assumed the burden of the false floor, while concrete for the floor of the chute and the bridge at the front was being poured. This bridge, six feet behind the shaft-timbers, extended from a point eight feet below the station-level to within two feet of the bottom of the chute, the lower part of the front being of 6-in. plank. Forms for the concrete floor of the station, which is also the top of the chute, were then built, the bottom and front being lined with steel plate. This job was completed without any appreciable delay in the regular mine work.

In opening a new level the procedure follows the regular methods of square-set stoping. A cross-cut is driven to the ore, drifts are started each way to expose the lode. Cross-cuts at irregular intervals determine the width of the orebody or the presence of branches on either side of the main vein. It may be remarked that under systematized development these cross-cuts are being placed so as to correspond with those on the level above, due reference being made to the size of the block to be mined. A raise in waste-rock is usually started off the second or third floor of a stope to provide, aside from ventilation, a passage for waste-filling. As soon as the drift has reached a point 300 or 400 ft. from the shaft a raise is started to make connection with the level above, and thus establish the circulation of air.

The first step in mining an ore-shoot is to remove the sill-floor, thus defining the probable limits of the shoot as it goes upward. Sill-set posts are placed at 6-ft. centres both girt-wise and cap-wise; these are 8 ft. 10 in. long; posts for the regular floors are 7 ft. 10 in. long. Round timbers are used exclusively, the diameter varying from 10 to 36 in., although the usual size is 12 to 14. No sills are laid, the posts resting directly on the rock. Recently it has been customary to drive the sill-floor only one set wide, opening the vein on the second floor, instead. This makes easier the work of keeping the sill open for tramming ore, waste, and timbers.

The next step is to build a chute-mouth and to start a two-compartment ore-chute and manway, which is raised as the stope advances upward. Two adjoining square-sets, properly situated with reference to haulage on the

sill, are selected. The chute is 'bricked' in a fashion similar to the skip-chute mentioned previously. Blocks, 20 in. long, of round timber, are substituted for 12 by 12-in. square pieces, and layers of blocks are alternated with round timbers, 6 to 8 in. diameter, spiked between the posts. The wear is confined largely to the end of the bricking-blocks, and a chute so constructed requires the minimum of repair. The manway is lagged with plank. As stated, this chute is advanced floor by floor as the stope rises. A stope averaging four or five sets in width will generally require chutes at intervals of 50 ft., while a narrower one will not need as many in proportion to its length. Normally, after the third floor is reached, operations will require two sets of miners and timber-men, one at each end of the stope on the top floor, while shovelers will be working on the floor beneath. At the same time they will be filling the next lower floor with waste supplied from the level above through the chute-compartment of the original raise. Ordinarily temporary track is laid and a regular mine-car is used for distributing this waste. The character of the ground makes it imperative that the filling be not neglected; waste cross-cuts on stope-floors must sometimes be driven to obtain filling material. Especially on the lower levels, where the walls are not so good and the orebodies are fractured and faulted to a greater degree than above, particular attention is paid to keeping the filling advanced as far as possible. If, as sometimes happens, the pressure of a block of ground becomes too great and caving ensues, the recovery of the ore is a slow and costly operation. Skilled miners catch up the ground and subsequently remove the ore by under-hand mining.

In spite of every precaution, there is continual difficulty in handling large stopes, 200 to 300 ft. long, and 20 to 40 ft. wide, when the entire shoot is mined as a single unit. The large horizontal area of open space frequently gives too much chance for shifting ground, so that trouble is averted with difficulty—if at all. Even though no cave results there is extra expense in angle-bracing and doubling-up timbers, and in building waste and timber bulkheads. In order to avoid this, the ore on the sill is blocked out by means of drifts and cross-cuts, after which successive sections of 50 or 60 ft. along the strike of the lode are mined. Each block includes the full width of the vein and is mined exactly as a separate stope according to the plan just outlined, except that the sets next ground yet to be stoped are lagged, before filling, so that no trouble is experienced with the subsequent removal of the adjacent block. This can be started as soon as the first stope has reached a height of six or seven sets. The great advantage is that a stope of this size can be run through from level to level rapidly, so that the overlying ground has little time to settle, and the amount of open ground on a horizontal plane is minimized. This procedure is in accord with the plan for the more orderly and deliberate mining that followed the rush of war-time activity, and it is working out with notable success. Down to 1900 ft. the levels are 100 ft. apart, but the next is at 2050 and hereafter the interval is to be 150 ft. This will effect economy by reducing by one-third the amount of drifting,

cross-cutting, and silling either on the first or second floors. However, it will increase the period required to mine a block of ore, and may prove disadvantageous on that account. In addition there is the possibility of overlooking small masses of ore between levels that might be found by more frequent cross-cutting. Detailed geological maps are kept up to date, however, so that this should be a minor drawback.

As can be seen from the map of the 1600-ft. level, a lateral—here in the foot, but on other levels in the hanging wall—is generally driven as a permanent haulage-way to and from the stopes distant from the shaft. It is more economical to carry the laterals in waste rock and drive connecting cross-cuts at intervals, than to maintain the sill-drifts through the ore. The expense involved in replacing and repairing timbers, and otherwise keeping open the necessary workings, is indicated by the record of workmen daily engaged in this work, which regularly averages 80 men. This, at the present wage-rate, adds approximately 60c. per ton to the cost of mining, and, in fact, it is an unusually expensive item as compared with the cost of repairs in other districts or even other mines at Butte. It is due solely to the exceptionally heavy character of the ground.

The standard raise is a regular six-post two-compartment combination of chute and manway. It may be advanced vertically, or by an angle-offset, which may be in the direction either of the long or of the short dimension, in which case the chute must necessarily be beneath the ladder compartment. The sets are the same size as the ordinary square-set, so that there is no difficulty, in any case, in making the proper connection between the raise and stope timbers. A special cribbed raise, either vertical or on an incline, has certain advantages in that it is slightly cheaper, and requires less work to maintain in good condition. The timbers used are 5 by 10 in., laid skin-to-skin on the flat side. This type of timbering is desirable when the raise is to be used only for ventilation, as a passage for men, or for the transfer of supplies or waste. As a working raise for a stope it has the drawback of being difficult to tap to draw waste for the successive floors, and, especially if inclined, it renders difficult the task of standing the adjacent stope-timbers.

A phase of underground operations that is rapidly becoming of more importance is the work of the cement-gun, commonly termed 'guniting'. Briefly, the process is this: A dry mixture of portland cement and clean sand in the proportion of 1:3 is fed into the hopper of a machine, from which it is forced by pneumatic pressure through a large hose to the gun-nozzle where it is mixed with a regulated stream of water. The resulting plaster is 'shot' in a rapid stream against the wall or roof, where it adheres and soon 'sets' on the surface that is to be coated. The nozzle is manipulated by hand after the fashion of a fire-hose and any desired thickness from $\frac{1}{4}$ to $\frac{3}{4}$ inch can be applied in a single or in several successive coats. The surface may be a rough rocky wall from which any loose lags have been removed, or timbers or planks that have been covered with some sort of metal-lathing. Ordinary fine-meshed wire poultry-netting serves well, although the

regular metal lath is better. One of the particular advantages of 'guniting' is the protection to timbers against fire; it also preserves timber by excluding air. When applied to the rock itself, a coat of gunite prevents slaking and crumbling, and in so doing forestalls the loosening and slabbing-off of large pieces of rock. As an experiment, a cross-cut in waste, approximately 600 ft. long, was gunited without timbering; the cost was 35% greater than the cost of timbering would have been, but the expectation is that the walls and back will require virtually no attention whatever and that the extra cost will be much more than offset by saving in maintenance. In the Black Rock mine all the stations at the No. 2 and No. 3 shafts are gunited, as well as the connections between the two stations on each level. All fire-doors, of which there are several on each level, some of the motor-barns, underground pump-stations, water reservoirs, and other miscellaneous places are protected in similar fashion. The sand and cement are put through a concrete-mixer on the surface, and the dry material sacked for distribution underground. The work of running the machine is not agreeable and the operators are paid 50 cents per day above the regular rate. A willing man, after some experience, generally becomes quite expert at the work and the cost of a given job depends to a considerable extent on the number of new men who have tried their hands at the nozzle.

Haulage is done by electric locomotives of the storage-battery type; this style of motor was originally selected in preference to the trolley system. It is significant that in several of the neighboring mines of the Anaconda company where trolley locomotives have been in use, they are being replaced by the other kind. Aside from avoiding a constant source of danger the battery-motor system is more simple, more flexible, and more economical. Two batteries are provided for each motor and one is charging in the motor-barn while the other is in service. On the busy levels a re-charged battery is required each shift. The motor can handle a train of 10 to 12 loaded mine-cars on a fairly steep grade and with the assistance of a little sand on the track performs very well under conditions of severe service.

THE placer camps throughout the Yukon valley, it is estimated, will yield \$4,485,000 for the season of 1920. The dry season caused a decrease in the output of almost every camp. Hydraulic operations, consequently, have been much curtailed. Yields of the interior of Alaska and the Yukon for the season drawing to a close are estimated by competent authorities as follows: Dawson, \$1,500,000; Fairbanks, \$750,000; Tolovana, \$750,000; Iditarod, \$500,000; Tacotna and Ophir, \$500,000; Hot Springs, \$100,000; Ruby, \$100,000; Koyukuk, \$75,000; Circle, \$70,000; Marshall, \$50,000; Forty Mile, \$50,000; Rampart, \$20,000; Chandler, \$20,000; total, \$4,485,000. In commenting on this situation the Dawson 'Daily News' observes that, if the decrease in gold production continues, it will be necessary to restore the purchasing power of gold by bonus or otherwise as low-grade alluvial gravel cannot be worked under present conditions.

THE SALMON RIVER

THE PREMIER MINE

Notes on the Salmon River Mining District

By CHARLES E. PRIOR

The Salmon River mining district is in the Portland Canal mining division of north-western British Columbia. It is about 700 miles north of Vancouver and on the southern edge of Alaska. The district is three to six miles wide and 12 miles long, embracing an area of 60 square miles. The centre of the district is 16 miles from the dock at the town of Hyder, Alaska, situated at the head of the Portland Canal. The Stewart, or Bear River, district is immediately south.

The first mining activity in this region dates from 1898, with the arrival of Burgess and his party of 60 adventurers, at the head of the Portland Canal, in May of that year.¹ The purpose of this expedition was to locate gold-placer claims on the upper Nass river. These men, of whom only a few were bona-fide prospectors, lost heart after a fruitless search of a few months and gradually drifted back to civilization. However, some of the party, in wandering through the Bear and Salmon valleys, observed outcrops of quartz, containing metallic minerals. The news of these discoveries spread and attracted the attention of prospectors to this region, particularly to the Bear River district.

In 1904 the Big Missouri claim was staked, but not until 1910 was any real interest taken in the Salmon River district. At that time derelicts from the mining boom in the neighboring Bear River district wandered over the dividing ridge and were attracted by outcrops showing promising quantities of low-grade sulphide ore with occasional streaks and bunches of high-grade silver ore. A great part of the country was staked at this time, including the groups of the Hercules, Cascade Falls (now in the Premier group), the Indian, and the Bush.

From 1910 to 1917 considerable development work was done on these prospects, mainly in an effort to develop enough of the low-grade complex sulphide ore to merit exploitation on a larger scale. In 1917 R. K. Neill of Spokane, and associates, optioned the group of claims belonging to the Salmon Bear River Mining Co., which had been optioned and explored previously by several other parties. Under the direction of Mr. Neill, the upper or No. 1 adit-level on this property was advanced and in eight feet entered high-grade silver-gold ore. This was in September 1917. The subsequent shipment by Neill of 514 tons of ore, averaging \$330 per ton, to the Tacoma smelter attracted the immediate attention of the outside mining world. In the fall of 1919 a working interest in this property, now the Premier Gold Mining Co., was acquired by the A. S. & R. Co. and associated interests. Since then shipment of ore, development of the mine, and the erection of a 100-ton flotation-cyanide mill have proceeded under the management of Dale L. Pitt.

The finding of a persistent shoot of high-grade ore in the Premier mine quickened interest in the various prospects of the district. Development work was started on the Big Missouri group by Sir Donald Mann and associates; on the Northern Light and Spider groups by the Algonquin Development Co., a Belgian Corporation; on the Forty-Nine group by the Forty-Nine Mining Co., Ltd. of Vancouver; on the Unicorn group by J. R. McDonald; on the Indian group by the Indian Mining Co. of Prince Rupert, B. C.,—in fact, practically every showing in the district was explored. This exploration work was done by short adits, open-cuts, and, in depth, by the diamond-drill.

The boom expected in the summer of 1920 did not ma-

¹'Portland Canal News', July 4, 1920.

terialize, principally because wide publicity was given, and wisely so, to the fact that it was not a 'poor man's country' and that practically all the ground had been located. To the time of this writing, August 1920, the Premier is the only mine that has shipped any ore.

The climate of this coastal region of British Columbia is characterized by exceedingly heavy precipitation of both rain and snow, long but not severely cold winters, and short mild summers. Precipitation in the Salmon River district, 1919-'20, at an elevation of 2600 ft., averaged as follows: snowfall, 55 ft., rainfall, 30 in., or a combined precipitation for the year of approximately 100 inches of water.

The deep U-shaped valleys and the rounded mountain tops suggest at once erosion by glaciation. The lower valleys and slopes are densely timbered with spruce and hemlock. The upper valleys are occupied by glaciers. Elevations range from a few feet to 7000 ft. above sea-level.

Owing to the thick growth of timber and underbrush, the comparatively few exposures of rock, and the shortness of the summer season, prospecting is arduous and slow. Excessive transportation costs, adverse weather conditions, and uncertain migratory labor, are some of the hard conditions under which a pioneer operator in this district must endeavor to accomplish results. However, costs should be reasonable at a going mine and mill because an ample supply of water, plentiful and easily accessible timber, and the facilities for working mines by adit-levels are favorable to low costs.

Geologically, the Salmon River district is at the contact of the great batholith of grano-diorite, which forms the coast-range of British Columbia, and the volcanic and sedimentary rocks of the interior. It is an interesting fact that most of the important ore deposits of British Columbia are closely associated with this batholith of grano-diorite. The copper deposits of the Granby mine and the Britannia mine, the silver deposit of the Dolly Varden, and, in the interior, the gold deposit of the Hedley (Nickel Plate) mine and the copper deposit of the Canada Copper Corporation, are all in proximity to this grano-diorite intrusive.

R. G. McConnell's diagram² shows three principal formations in the Salmon River area: first, granite, grano-diorite, and quartz-porphyry; second, the Bear River formation, consisting of porphyry, tuffs, breccias, and agglomerates; and third, the Nass River formation, consisting of argillite and tuffaceous sandstone. J. J. O'Neill³ believes that the oldest rock series, tuffs and tuffaceous conglomerates, are overlain by the Nass series of gray shale and sandstone in the north-western and north-eastern parts, and have been intruded first, by the grano-diorite of the coast batholith, and second, by numerous dikes ranging from quartz-porphyry to augite-porphyry. The tuffs and breccias are found in a variety of colors—reds, grays, greens, and lavenders. This series pre-

dominates in the district. The Nass series of shale and sandstone occupies only a very small part of the district and evidently has played no part in the distribution of the ore. The porphyry and grano-porphyry dikes are the principal dikes of the district and vary from those of very fine-grained texture, which are with difficulty differentiated from some of the tuffs series, to the types containing large feldspar crystals and hornblende.

The quartz-porphyry is the principal ore-rock of the district. It is locally termed 'greenstone', by reason of its distinct green color. Orebodies are found in mineralized shear-zones in the porphyry; generally they lie close to the tuff. Regional shearing has developed these numerous shear-zones, the making of which was accompanied by silicification and pyritization of the greenstone itself. In many places the porphyry has been altered to gray and green schist. This schist greatly resembles that of the Britannia copper mine, although here usually the alteration has not been so complete as there.

The orebodies are in the form of lenses within the mineralized shear-zones. They are irregular in shape, having no well-defined walls or sharp limits between ore and waste. The ores of these deposits can be divided roughly into two classes: the high-grade quartz ore and the low-grade sulphide ore. There are no important oxidized ores in the district.

The sulphide ores are the more abundant. The metallic minerals in these ores are usually sphalerite, pyrite, galena, and small amounts of chalcopyrite, argentite, and native silver. The zinc-blende is usually the most abundant of the sulphides. Galena, in this district, carries little silver. A good example of these low-grade complex sulphide ores is found in the orebodies of the Big Missouri. The showing at this mine consists of huge surficial lenses of sulphide ore in altered greenstone. According to J. J. O'Neill,³ the ore averages from \$6 to \$10 per ton. Three-fifths of this value is due to the zinc content, one-fifth to the lead, and one-fifth to the precious metals.

An analysis of typical high-grade ores of the district is as follows: silver 148.6 oz., gold 6.18 oz., copper 0.5%, lead 1.7%, zinc 3.3%, iron 7.6%, insoluble 75.1%, lime 1.3%, alumina 6.5%, and sulphur 8.6%. The metallic minerals usually present are argentite, pyrite, stephanite, pyrrargyrite, native silver, tetrahedrite, sphalerite, and galena. Argentite is the chief silver mineral. The gangue is quartz and silicified greenstone.

E. E. Campbell⁴ believes that the high-grade ores of this district are entirely of secondary origin and that the oxidized portions of the outcropping orebodies have been removed by glaciation. Mr. O'Neill believes that the ores are of secondary origin and that the enrichment was produced by secondary mineralizing solutions entering re-opened fissures in the primary ore-zones. Victor Dolmage⁵ recently made a comprehensive study of microphotographs of specimens from the district. He con-

⁴Mining and Engineering Record', Vol. XXV.

⁵Journal Canadian Mining Institute', June 1920.

THE LANDING AT HYDER

cludes that "the processes of secondary enrichment may have played only a very subordinate rôle, if any, in the formation of these rich silver deposits". Dr. Dolmage here means secondary enrichment by descending solutions. The principal high-grade ores of the district were unquestionably produced by enrichment of the primary ores by secondary mineralizing solutions, but not by descending solutions containing metal dissolved from overlying ores. A description of the Premier ores and their occurrence will explain this.

Quartz-porphyry dikes and bands of tuff are roughly parallel in the Premier mine and vicinity and have a general strike of S. 30° E. The individual porphyry dikes are as much as 1000 ft. wide, the individual bands of tuff up to 300 ft. in width. The tuffs are intruded by dikes of fine-grained hornblende-porphyry, which is probably the youngest rock in the district. Regional shearing has cut across both the porphyry dikes and the tuffs and has produced in the porphyry a mineralized shear-zone. This mineralized shear-zone bears N. 80° E., dips from 70° to 85° north, and is from 40 to 100 ft. wide.

The orebodies are found as irregular and ill-defined shoots within this highly silicified shear-zone in the greenstone. Pronounced cross-fissuring at an angle of 45° to the main line of shearing has taken place. Masses of high-grade silver-gold ore have been formed at the intersections of these cross-fractures with the main shear-zone. This high-grade ore follows the hanging-wall side. The high-grade ore-shoots do not outcrop. Ore-shoots of milling-grade are in the foot-wall side of this shear-zone. In places, the ore follows the cross-fractures from the ore on the foot to the ore on the hanging wall. No displacement by faulting has been found.

The principal silver-bearing mineral is argentite, which is found both crystalline and amorphous. Ruby silver, native silver, and gray copper are the other silver-bearing minerals. The chief gold-bearing mineral is pyrite, of the yellow fine-grained closely-knitted variety; the white

large-cubed variety is generally barren. The gangue is quartz and silicified quartz-porphyry. When the price of silver is one dollar per ounce the ratio of the value of the gold varies from 1:1 to 1:6; the average for the shipping-ores is probably 1:2.5; the average for the milling-ore will show a proportion more nearly equal. The high-grade silver ore of the Premier mine was formed by the cross-fissuring re-opening the primary ore, and the subsequent entry of enriching solutions through these fissures and the precipitation of secondary minerals from these solutions in the primary ore. The milling-ore is probably primary ore that has been enriched to a small extent by the solutions that formed the high-grade ore.

S. J. Schofield, of the Canadian Geological Survey, is, at the time of writing, working out the structural geology of this district. The report of his results will probably be available within a year and will be of great assistance to operators in this district.

GOLD-BEARING BLACK SAND, such as that found on the beaches of Alaska, can be satisfactorily treated by amalgamation in a revolving barrel. Caustic soda should be used as an aid in this amalgamation. The use of cyanide during amalgamation or before amalgamation will result in a loss of 5 to 10% of the gold through its solvent action. If the quantity of sand is too great to amalgamate the entire amount, it may be concentrated by employing a classifier, whereby the bulk is reduced to approximately 40% of its original weight with very little loss of gold. The coarser portions of the sand, which is free from gold, should be removed from the classifier-feed. The water-supply should be constant, so that the upward stream in the sorting-column of the classifier does not vary from 35 ft. per minute. If much of the gold is very fine the classifier-overflow or tailing should be passed over a screen to separate the finer portion which may then be amalgamated in the revolving barrel.—U. S. Bureau of Mines. Reports of Investigations.

The Ore Deposits of Mexico—VI

Ore Deposits in Surficial Flows of Igneous Rock

By S. J. LEWIS

We now pass to the second class of deposits in igneous rocks, namely, those found in the thick and extensive flows that have covered immense areas of southern Mexico. These ore deposits are correspondingly larger and more important commercially than those we have studied in the Zacualpan area. On account of the nature of the rock-masses and their chemical effect on ore deposition, it will be convenient to subdivide them into orebodies found in silicious rocks such as rhyolite; those found in rocks of an intermediate type, as andesite; and finally, those at the basic end of the series, as in basalt or andesite closely approximating basalt.

1. Igneous deposits in rhyolite: Mezquital del Oro. These gold mines in southern Zacatecas, close to the Jalisco border, are good examples of Tertiary gold deposits, presenting many of the typical features. The veins occur in an extensive flow of rhyolite, at least 500 m. thick. Later shale, similar to the Pleistocene shale of the not distant Ameca valley, overlies the flanks of the rhyolite sheet east of the deposits. Oxidation of the iron minerals in the rock has dyed the whole surface a bright red, which in the fresh rock is reduced to pale shades of pink. The Mezquital river has cut a tortuous and picturesque course through the flow, with canyon-walls as much as 300 m. high, and drains into the Lerma, or Santiago, river at the little village of San Cristobal, about 30 km. south of the mines. The river cuts squarely across the gold-bearing veins. The latter have been worked since before Spanish times in a crude way. As a whole, the deposits are low-grade and have not been profitable for many years.

The veins have been pretty well explored over a length of 1000 m. on the strike and to a depth in the principal shaft of 300 m. They are narrow quartz veins, parallel and close together, forming a gold-quartz lode that is typical of its class; it is irregular as to strike, dip, and distribution of mineral. The valuable metal is gold; the typical ore carries from 5 to 50 gm. gold per metric ton, with from 8 to 50 gm. in silver, which, of course, is negligible. Lead occurs rarely, principally in upper levels as fine silver-bearing galena, with a little copper as oxide and carbonate. All the bullion ever made at the mines, although of exceptional purity, shows a trace of copper. Manganese occurs sparingly as black oxide in dendritic crystals within minute fractures. The gold itself is invariably either in the form of minute scales scattered through the rhyolite, or in extremely beautiful leaves and fern-shaped crystals, deposited on quartz surfaces in the vein, in minute cracks or openings. Some of the specimens taken out of the quartz veins have been

strikingly fine, with the fresh fern-like gold crystals powdering the surface of the quartz. The vein-filling is clean sugary quartz, frequently showing banding and comb-structure and sometimes quite high-grade; however, the principal mineralization occurs in the rhyolite wall-rock, due to an exceptionally thorough impregnation of the latter by hot solutions working outward from the channels, through the brecciated wall-rock and quartz stringers between the veins, and into the rhyolite. The quartz veins are from 30 cm. to a metre in width, but the enrichment of the wall-rock has frequently been so thorough as to make orebodies 8 to 12 m. wide and reaching from the lowest level to the surface.

Three well-defined stages are distinguishable in the

PART OF MEXICO

deposits; first, the general fracturing of the rhyolite sheet, due wholly to tension on cooling, and the formation thereby of the lode of quartz stringers, connected by innumerable small fractures running from one vein to another; second, the entrance of alkaline gold-bearing solutions into all the openings during a brief but intense recurrence of volcanic action, which solutions came from the heated depths of the mass and precipitated their gold when they reached the higher and consequently cooler portions of the fracture-zone. Lastly, the veins were heavily faulted by later movements across the axis of the lode, which faults have exercised an important influence on oxidation and enrichment.

In the first stage, there seem to have been two slightly-separated periods of tension, in the first of which the cooling fractures occurred in the shape of three closely asso-

ciated and nearly parallel cracks, that is, as a typical lode-fracture. A fourth crack followed approximately the same line of weakness, but soon diverged from the others, making a system in which the fourth fracture, dipping south, intersects the other three, dipping north. (Fig. 20.) This condition is visible over a length of about 500 m. The intense cracking and shattering of the rhyolite, with the mutually intersecting channels of all sizes, made a stockwork, peculiarly favorable for the formation of orebodies. The more important fractures form the sticks of a fan, opening out as the veins go toward the surface. The gold-bearing solutions rising to this zone filled the myriad cracks and channels, so that the rhyolite in the shattered zone adjoining the fractures was saturated with the hot solutions like a sponge. When change in chemical condition caused precipitation, the gold crystallized in place in all the shattered area. At certain points where conditions were especially favorable, pockets of rich ore were formed, so that the deposits are a succession of such pockets connected by the narrow quartz veins. There is no impoverishment on passing out of the lenses into the veins. The latter are frequently even richer; the difference is merely in the thickness of the ore. That the gold-bearing solutions were hot and not silicious is shown by the much-softened wall-rock, which has been highly altered, especially as regards the feldspars. Under the microscope it shows abundant flow-lines arranged in zones, with much intergrowth of quartz and feldspar. The larger orthoclase crystals are much decomposed. All the minute fractures and seams in the section are filled with scales of hematite. The two stages of alteration are therefore both indicated: the alteration of the feldspars by hot alkaline solutions, and the oxidation of the original iron sulphides that were doubtless associated with the gold in the primary solutions.

In the third, or enrichment, stage, strong fault-fractures cut across the lode at high angles, with a displacement of several metres where known, and with high enrichment on both sides of the faulting. There are three principal sets of displacements, in all of which the upper face of the movement seems to have received more enrichment than the lower. The great east fault at one end of the mines and the San Carlos fault at the other end have practically cut off development at their respective places; the one between, near the middle of the mine, was successfully passed, and systematic exploration would probably pick up the veins beyond the other two. That oxidation along the fault-planes has enriched the deposits seems certain, especially in pockets near the surface. The greatest pockets in the mine, however, seem to have been found at about 100 m. below surface, whence they went down on ore to the bottom, about 300 m. Below this level, the fractures, reduced to two fissures, go down with spotty mineralization, in which there is a tendency for the silver to increase in ratio to the gold.

The marked affinity of gold for silica could hardly be better illustrated than in this deposit. Rhyolite is the most acidic or silicious of the rocks; and although the magmatic solutions that saturated the ground doubtless

carried other metallic minerals, only the gold, to all intents and purposes, came down from solution.

Even more interesting is the dissemination of the gold all through the shattered rock; we have here a fine illustration of reactions in a solid medium. The thorough shattering made the rhyolite an immense container holding vast quantities of the primary silicious mineral solutions; the later alkaline gold-bearing solutions diffused into the rock as they would into blotting-paper, reacting with the existing silicious solutions and depositing the gold in lenses or ore-shoots at irregular intervals in the structure, but grouped along the lode and separated by barren spaces. In a very definite way and on a great scale it is an example of the making of gold orebodies by the reactions discussed in the introduction to this part of our study.

2. Igneous ore deposits in intermediate andesites. The Hostotipaquillo district in north-western Jalisco (Fig. 21). Up to the present, the greatest silver producers of Mexico, and therefore of the world, have been in the Pachuca deposits of this type. They differ from those discussed principally in the extreme thickness of the igneous formation, and consequently in the depth to which fracturing and mineralization go down. The lodes of Pachuca are well known and have been profusely described. The veins of the 'Hosto' district, as, for brevity, it is usually called, have become of great importance as silver producers in the last ten years, and illustrate the same conditions very well without being so highly developed or so well known as those of Pachuca.

The silver lodes of the Hostotipaquillo district are in Tertiary lavas of intermediate chemical composition, being a series of andesite and rhyolite flows, bedded conformably on top of one another to a thickness of over a thousand metres. The important deposits are in the andesites. Considerable microscopic work has been done to show that the andesite assumes a dacitic phase now and then, but my own observations in the district have convinced me that such differences or variations in the rock have had little or no influence on the deposition of ore.

The cooling of these great masses, and the settling on their beds, have induced great fracture-systems, which, after mineralization have been extensively faulted. Such cross-faulting, both in plan and in strike, is an important feature of these deposits (Fig. 21). The effect of the faulting has varied with the conditions: there are many cases where the faulting has caused leaching of the silver mineral, especially in connection with brecciation; while there are others where the effect has been to make heavy enrichment.

Many of the mines were worked by the Spaniards, and, of course, were not sold in modern times to the present American owners until the orebodies were thought to be exhausted. Exploration in depth and beyond faulted areas has been fruitful; probably the most conspicuous example is Cinco Minas, the principal mine of the district.

Throughout this district the fractures are fairly regular in strike but show variation in dip, with a change of mineralization sometimes accompanying the variation.

The fractures are simpler than the Mezquital example, generally consisting of a principal channel and one or two smaller veins in one or the other wall, usually well mineralized. The fractures, however, are of immense size, the orebodies varying from a metre in width on the wall-stringers, to 8 or 10 m. wide on the principal channels. The veins consist entirely of silicious replacements of the brecciated andesite, cemented by massive quartz. The gangue-minerals are quartz, calcite, and rhodochrosite, the last being of considerable importance as an associate of the silver minerals, which are almost wholly finely divided argentite, with considerable native silver and

The distinguishing feature of the district is the occurrence of large areas of enrichment, usually as lenses, in veins of otherwise barren quartz. There are, besides, many large and well-marked veins in which no orebodies have ever been found. The highly complex faulting to which the veins were subjected after mineralization has brecciated great areas, and it is possible that silver leached from these areas has found its way to effect enrichment elsewhere. In Cinco Minas, a drift on the principal tunnel-level showed over 300 m. of shattered and leached quartz, with practically no silver, intervening between the greatest of the old orebodies and its San Juan neighbor.

At San Carlos Shaft

FIG. 20

occasional, rather rare antimonial combinations. The gold contents in general are not important, being about a gramme to the 'kilo' of silver. Lead, iron, copper, and zinc are present as sulphides, but not to a significant degree. That these base minerals were not precipitated at the same period as the noble metals is shown by the occurrence on the 200-ft. level of the Cinco Minas, in beginning the modern exploration in 1909, of lead ores that looked like rich silver-bearing lead ores found near the surface, but proved to be almost barren of silver. This condition was general for a zone intermediate between the bottom of the old orebodies and the beginning in depth of the new ones.

The manganese, frequently abundant as black oxide in a form that does not interfere with cyaniding, is yet in some of the mines a cause of metallurgical trouble, so that a few of the large orebodies of the district have up to date been unprofitable.

The orebodies at this and the other mines are chimneys of comparatively short length that go down as lenses succeeding each other to a great depth. Up to the present, profitable mineralization has been proved to 1600 ft. below the outcrop, I am informed.

The three stages of fracturing, mineralizing, and oxidizing, in these deposits, are strictly comparable to the same stages in the Mezquital deposits, with local differences of special interest, suggesting a comparison with the El Oro deposits. It seems likely that in the 'Hosto' deposits mineralization came in two separate periods: the first of primary nature, in which metallic base sulphides were deposited, with some silver, the gangue being predominantly calcite, though with some quartz, pyrolusite, and rhodochrosite; the second period came from wholly silicious solutions and probably added materially to the precious metal content of the ores. At a number of scattered mines in the district I have found excellent pseudo-

morphs of quartz after calcite, generally in connection with highly enriched ore. Perhaps a more interesting point of difference is the fact, already alluded to, that faulting in the district has destroyed ore deposits rather than enriched them. At Cinco Minas, step-faulting of a most interesting and complex character has in many places caused displacements in the enriched vein, of from three to six metres, shattered the quartz, and leached it. Similar occurrences of a similar kind are visible in the old San Domingo and Rayas veins on the Santiago river; in fact, it is a feature of the district. The effect in all cases has been to make long stretches of shattered and unprofitable vein-matter, separating important chimneys of practically pure silica enriched with silver sulphides. Surface agencies working on these chimneys under the fiercely oxidizing conditions of the climate, where the surface is alternately baked and chilled, or saturated and then dried to dust, in the manner characteristic of arid regions, have made oxidation an important factor in the formation of rich orebodies at the surface; in many cases these bonanzas have been followed down to intermediate depths with great profit. The limit of the very rich ore seems to be about 200 m. below the outcrop. Below that point the ore shows little secondary influence and is therefore lower in grade, although still profitable.

A curious feature of the extensive faulting and crushing of the veins here, has been the formation, in at least two cases that I have seen, of silver placer deposits from the débris. The destroyed vein, instead of being leached in place, as in other cases, has been rolled down into suitable hollows of the old surface, and pressed into vein-like masses by the weight of the accumulated washings from above. Such deposits, of course, have their value strictly limited by the ore measurable.

The formation of silver-bearing lenses in the quartz veins, in vertical or inclined zones having local constrictions and widenings, is strictly comparable with the formation of the gold chimneys in the Mezquital rhyolite. The fact that in the one case we have andesites of intermediate composition giving rise to silver precipitations, and in the other case we have acidic rocks giving rise to gold aggregates, certainly supports the view that the whole process is a chemical one, in which special conditions of precipitation result from the chemical effects of the wall-rock and the circulating solutions. The notable feature is the selective action of pure quartz or silica for gold, which will be seen to vary through the silver orebodies of the intermediate rocks down to the deposition of the baser metals in the rocks of the basaltic or basic extreme.

3. Igneous deposits in basic andesites or basaltic rocks. The Amparo mine,* two hours ride from Etzatlan, in the State of Jalisco, is an excellent example of ore deposits in the least silicious eruptives. The rock is an augite-andesite, occurring in a mass of great thickness and Recent age. Strictly speaking, there is little difference in kind between this formation and those just discussed,

as the Amparo rock-mass, while not a thin surface flow seems to be made up of a series of outpourings or thick extrusions, which made their way through the older formations and constitute the present surface. Flow-lines and abundant glass in the ground-mass are easily seen in thin sections of the rock, especially in the comparatively undecomposed rock of the Mesa Colorada, just above the mine and well away from the fracturing. This shows important differences from the wall-rock in the mine, and it thus seems possible that the mass was built up by successive flows of the same or similar material. In the mine-workings there is no evidence of stratification or separation of flows from the surface down to 1300 ft. in depth.

From Etzatlan, where the rock is of more intermediate character and where numerous occurrences of black obsidian are found, over to the Ameca district on the other side of the Amparo mine, is about 20 kilometres (Fig. 22). Here the same rock occurs as on the Mesa Colorada and it extends considerably to the west, its highest point being the mountain peak about 10 km. from the mine. The thickness of the mass is certainly not less than 1000 m. Its flanks are covered with recent rhyolite tuffs, deposited after the topography had been carved nearly into its present relations. There are no sediments nearer than the Pleistocene shales of the Ameca and Ahualulco valleys, 20 km. west.

The andesite is the ore-bearing rock of the district. It is generally greenish-gray where moderately oxidized; the rock of the near-by mesa is much darker, sometimes nearly black, and quite fresh in fracture. Where oxidation has been more thorough, the mine-rock is stained a purplish-red with iron oxides; epidote has developed sparingly.

Microscopic study of a series of Amparo rock specimens collected at more or less regular intervals of depth and at varying distances from the veins, has brought out some interesting facts bearing on the origin of mineralization. The dominant feldspar in most of the specimens is plagioclase, generally in well-shaped crystals, which show roughening and decay only where the ground has been much disturbed. With increase of depth, the prevailing feldspar gradually becomes orthoclase, as is shown in a series of sections beginning at the surface and going down to the 1300-ft. level. Some of the intermediate slides show the orthoclase crystals in process of zonary alteration to plagioclase.

The ferro-magnesian constituent of the rock is nearly always augite in a wide range of alteration from augite in bright clean crystals, sometimes beautifully twinned, through skeleton crystal boundaries with alteration to chlorite almost complete, down to masses and stains of chlorite with no trace of crystal forms. This is seen in slides made from specimens taken from parts of the ground where heavy movement and crushing have taken place during the period of vein-formation. In such ground, the iron is thoroughly oxidized to a red hematite, staining all the fine cracks in the rock; where there has been less movement, there is notably less hematite.

The typical augite andesite assumes a trachytic phase

*By permission of the Amparo Mining Company, and with acknowledgments to James H. Howard, general manager, Etzatlan, Jalisco.

locally at depth, at a point well removed from fracturing, but it returns in a short distance to the type rock, the local change having apparently had no important effect on the mineralization. At about the 700-ft. level the

original unaltered rock seems to have been an augite-andesite with abundant large crystals of orthoclase and rod-like crystals of plagioclase in the ground-mass. Oxidation processes, whether working from the surface down-

FIG. 21

orthoclase begins to appear in some quantity, increasing unmistakably with depth both in crushed and uncrushed rocks. The trachytic phase shows hornblende instead of augite. In all there is much secondary magnetite in small

ward into the mass or working outward from a fracture into the walls, have caused extensive alteration of the large orthoclases to plagioclase at the same time that the augite has altered to chlorite. The tension to which the

FIG. 22

rounded grains; secondary calcite and chalcedony are also plentiful in the minute seams.

The most significant alterations are noted in specimens taken from the near neighborhood of fractures. The

rock has been subjected near the veins has crushed the large feldspars so that the rock from such points looks like tuff, with broken roughly-rounded grains of plagioclase and glass; a few metres away, in undisturbed

ground, it shows the crystals quite whole, though sometimes strained, and is easily recognizable as the typical andesite. Such crushing is especially common in specimens taken from levels which have been highly productive; that is, where movement of the ground has been most violent, crushing of the rock most severe. Where the vein suffers a local pinch and impoverishment, as on the 600-ft. level, the brecciation is not noticeable in thin section to any marked extent, and in general the rock looks fairly fresh. The evidence indicates that mineralization of the fractures and subsequent enrichment have been directly dependent on the ease with which circulation could take place; where fracturing has been heavy and thorough, we have enrichment; where the fracturing has been light and the channel is narrower and tighter, we have lack of enrichment.

There are few more interestingly complicated fracture-systems in the mines of Mexico than that of the Amparo mine; and it is this very complexity that is responsible for the enrichment, making effective the favorable chemical condition due to the interchange between the mineral solutions. One of the striking features is the presence of abundant manganese oxide in the form that does not interfere with cyanidation, from the surface down to the very lowest levels. It is quite well disseminated through the veins, and appears to have had considerable influence in carrying the gold down to the deep workings.

Three important stages of fracturing are distinguished in the mine:

A. The earliest movement is the San Juan lode, a strong fracture which in some places shows three well-defined parallel members. It cracked the ground in a general north and south direction, the result being a largely calcitic mineralization, introducing lead, zinc, iron, copper, etc., in small amounts, and abundant manganese. The dip of this lode is about 70° west (Fig. 22).

B. The next movement in point of time was the Dulces Nombres vein with its outlier, the Veta Verde, which latter has never been of commercial importance. The former cut through the San Juan cleanly in a northwest-southeast direction, displacing the separated sections by about 90 m. This stretch of nearly 300 ft. along the Dulces Nombres vein, joining the two pieces of the San Juan, became much enriched as a result of the dragging of the ground and the re-opening of the channels. The brecciated wall-rock and the gangue-minerals already existing in the fractures of the San Juan, became favorable points for deposition, and the Dulces Nombres lens became a short but deep chimney of well-mineralized ground. A marked difference is noted in the character of the second mineralization: whereas the first was markedly calcitic, the second is markedly silicious. This can be observed in the Veta Verde, which on account of its position on the extreme edge of the disturbed ground, did not participate in the re-opening of the channels to an equal extent with the other veins. Its mineralization is notably strong in calcite, generally in fine crystals formed in open cavities and based on the vein walls;

silica is not nearly so abundant as in the other veins, and the vein has not been profitable except in a few scattered spots. In the San Juan veins, pseudomorphs of quartz after calcite have been found down to the deep levels; the calcite persists also, so that on the deepest level the calcite and quartz are about equally represented. The freshly circulating silicious solutions doubtless exercised an enriching influence on the primary calcite deposition as regards gaining in silver and gold; in which respect the mine is another example of the enrichment by later silicious solutions, as at El Oro.

The dip of the Dulces Nombres fracture is about 70° east, that is, directly opposite to that of the San Juan.

C. The great fault-movement that cut the San Juan vein in the south was the latest and from an economic standpoint was the most important of the whole series of movements. The result apparently of settling of the whole upper portion of the mountain, it cuts across the southern half of the San Juan lode at a high angle, and dips about 60° north, displacing the veins about 10 m. to the east. The repeated up-and-down movement incident to such an important fracture ground up the rock-breccia into the finest particles of impalpable clay, and the gouge thus formed in the fault zone, from 30 cm. to a metre thick, acted as a check to circulation across the San Juan channels. The precipitation thus induced caused heavy ore deposition on both sides of the fault. The exploitation of the southern part of the mine has therefore taken the form of mining two separate, extensive, well-mineralized bodies; the first-known and lesser, on the upper side of the fault, terminating against the face of the displacement; the later-discovered and much larger body on the lower side of the fault, beginning practically at the surface of the displacement and going down practically without reduction of width or values about 1000 ft. Both bodies owe their commercial importance in large part, if not wholly, to the accidental interruption of the circulation and the resulting precipitation against the dam.

The ore is a silver-gold mixture, with the value of the minerals about evenly divided, the mill ore running about 8 gm. of gold with 300 gm. of silver.²⁰ The latter occurs principally as argentite with oxidation products. The gold is seldom or never visible either to the eye or the hand-glass. A good deal of brecciated and altered wall-rock occurs in various stages of replacement. Manganese has been already mentioned as very abundant from top to bottom of the mine, both as the black oxide and as the pink carbonate, rhodochrosite. The latter is probably more in evidence at the deep levels than the oxide. In depth the gold contents show no such sudden decrease as would occur in a Tertiary deposit lacking the manganese. They persist with great uniformity down to the deep levels, suggesting that the reactions necessary to carry gold down in iron solutions were undoubtedly greatly assisted by the presence of the manganese.²¹

²⁰With silver at 1912 prices. Of course, the ratio is changed now.

²¹W. F. Emmons, 'The Influence of Manganese in the Deposition of Gold Ores', Trans. A. I. M. E., Vol. LVIII, p. 232.

In studying this important ore deposit, one is struck at once by the great part that has been played in it by intensity of fracturing: when, however, the nature of the resulting mineralizations is compared with that of the other deposits in eruptive formations that we have been discussing, like the Mezquital rhyolite and the Hostotipaquillo andesite, the most striking feature of the comparison becomes the difference in mineralization as related to the difference in acidity of the wall-rocks. Mezquital, a mine showing thorough fracturing in a highly silicious mass, is a gold mine pure and simple, with hardly a trace of any other metal. Cinco Minas, in andesite of practically neutral composition but with a vein-system showing almost as complex fracturing as the other examples, is distinctly a silver mine, with practically nothing of other metals. Both classes of deposits show quartz vein-fillings with but little replacement of the wall-rock and with very small quantities of sulphides of the base metals. At Amparo, on the other hand, we have mines in andesite of the least silicious kind, carrying the most feldspar and iron minerals. Here, the result of mineralization is predominantly a deposit of sulphides of the base metals, lead, iron, and manganese in abundance, zinc and copper more sparingly, but the whole being emphatically a base-metal mine, with the silver and gold as mere traces, quantitatively speaking, although, of course, they are what give value to the mine. Putting it in another way, the deposits in rhyolite and neutral andesite present no metallurgical problem, except, of course, in the case of manganese silver ore. They are combinations of silver or gold with a quartz and calcite gangue, and the separation is not difficult; whereas in the Amparo the combination has been not only with the gangue-minerals, but with sulphides of all the base metals, requiring a high order of metallurgical skill for the separation.

The alkalinity of the wall-rocks clearly is a factor of great importance in determining what minerals shall be precipitated out of the circulating solutions. This is supported by our review of deposits in sedimentary rocks, which shows that mines in alkaline masses, like the limestones, are predominantly base-metal mines; whereas mines in the less alkaline rocks, like the eruptives, are pre-eminently deposits of the noble metals. If we review all our examples, we find that where the rock formation is highly silicious, but the mineral solutions were unmistakably alkaline, we get gold deposits with hardly a trace of other metals. Where the rock formation is intermediate or neutral and the mineralizing solutions at the most important stages were silicious, we get silver deposits, with the base metals still insignificant, though of more importance than in the former class; and finally, where the rock formation is least silicious or fairly alkaline, the general final result is the deposition of base metals, with such gold and silver as may have been brought in during periods of varying alkalinity in the circulating solutions. This is true from the operating point of view also, despite the fact that the few hundred grammes of silver accompanying lead deposits in limestones may mean a considerable profit, or the fact that

many of the great silver mines carry very appreciable quantities of lead and zinc.

Further proof of this relation is afforded by a brief glance at a typical copper camp in eruptives, like the Ameca district not far from Amparo. The condition there is complicated, however, by the presence of later eruptives intruding the formation.

The predominating rock in the Ameca copper district is a dark heavy basic andesite, even more alkaline than the Amparo rock, and sometimes closely approaching the basalts. Under the microscope it shows a dense ground-mass of plagioclase feldspars, in brilliant clean-cut rod-like crystals. The ferro-magnesian constituent is hornblende or hypersthene, and there is a great deal of pri-

FIG. 23. PHOTOGRAPH OF ESPERANZA VEIN, AT EL ORO*

mary pyrite in the rock, frequently visible to the naked eye. There are two classes of copper deposits in the district, owing their origin to the two kinds of rock intruding the andesites; first, the contact bodies, irregular in shape and tenor, occurring on the contact of a monzonite-granite intrusive with the andesite; and second, true vein deposits, occurring near porphyritic dikes of small thickness and nearly vertical in dip. The first class is exemplified in the Almoloya deposit, a little higher up the range than the similar Las Moras deposit. In both, the

*By courtesy of Charles Hoyle, manager for the Esperanza Mining Co., El Oro, and of T. A. Rickard. See also U. S. Geol. Sur. Professional Paper No. 68, plate 3, for a fine example of ribbon structure.

monzonite underlies the andesite and outcrops as a stock near the former mine. The granite shows the characteristic deep striations of the plagioclase crystals, visible without a glass. The west slope of the stock is covered by the andesite, and the contact has mineralized to an interesting extent with copper sulphides, practically to the exclusion of the other metals. It will be remembered that similar monzonite intrusions into limestone in the Coaleman country have already been cited as producing copper and iron.

The second class is best exemplified in the Magistral, the most important mine of the district. Here the best orebody occurred at the coming together of the two principal fractures, near the porphyry dikes. In all the known veins, the orebodies are of short length and go down in chimneys to the depth so far explored, about 200 m. below the outcrop. In the contact deposits, the usual secondary-silicate minerals are found abundantly, with a great deal of replacement of the brecciated rock. Three-cornered pieces of rock, completely altered to chalcopryite, are found in calcite gangue. The copper veins are similar, especially as regards replacement, which is really the distinguishing feature of the district. In all cases, copper is the sole recoverable mineral, the silver being almost negligible and the gold wholly so. There is the usual surface oxidation of the copper sulphides to carbonates and oxides. The gangue is hard and silicious, involving much sliming of the mineral.

The Santa Maria antimony deposits described in Part II of these articles, in which a base metal has been precipitated on a contact of two quite basic rocks, without a trace of the noble metals, will be recalled as another example of the influence of the wall-rock in determining the nature of ore deposition.

CONCLUSION. The practical object of the study of orebodies, is to enable us to find ore; and while chance certainly plays its part in the finding of precipitations that were determined more or less by chance, a knowledge of the habits of orebodies in a given district or in many districts is the best possible equipment for the miner.

In all that part of Mexico which from Spanish times has been known to possess silver-bearing veins, prospecting has been so thorough that in the vast majority of cases, the good mines of a district are well known, and the proportion of good strikes in prospecting for new mines is very small. This is not true of the lead districts of northern Mexico, simply because the Spaniards had not much use for the lead; however, there are comparatively few even of these lead mines that were not worked in ancient times.

The idea has been advanced in the foregoing pages that ore deposition is simply a record of a chemical interchange or series of interchanges, which has taken place in huge containers formed by fracturing of the earth's rocky crust. In searching for new orebodies, we search for a place where chemical conditions were favorable for precipitation; the surest way to find such a place, at least in Mexico, is to search in a locality where such precipitation has already been known to take place. That is, there is considerably more chance of finding ore in new bodies

in an old mine, than there is of developing profitable ore in a new prospect.

It should go without saying, that this statement is limited by the geological structure in which a given ore deposit occurs; there are many Mexican *antiguas* where only brief study is required to show that enrichment is not likely to continue to any reasonable depth, and exploration on old orebodies would therefore not be justified; in such a case, the winning of a profit would be dependent on the finding of new shallow orebodies near the surface. In the majority of cases, however, where the veins occur in thick rock-masses under the conditions of climate that we have in Mexico, exploration in depth, or beyond fault-planes, in old mines, may be expected to yield a high rate of success. In all cases, success depends on a cultivated faculty of observation, in which no detail is too insignificant, and which patiently and surely gathers a multitude of facts for correlation and study. With such a faculty, and with the intellectual honesty that causes the observer to accept a fact the moment it is observed, no matter how disturbing it may be to theories already formed, the finding of new orebodies in Mexican mines is accompanied by much less uncertainty than is prospecting for new deposits.

From the minute local peculiarities with which the miner has to deal and which mean for him either success or failure, it is a far cry to the cosmic viewpoint of the geologist who reviews the whole process of ore deposition from its beginning to the present day; yet it may be of interest to point out two facts that are often lost sight of: the limits of time and place in ore deposition. First, we note that nearly all the workable ore deposits of the country were begun and brought to their present state in a period that geologically is of the shortest; for the few hundred thousand years that make up Tertiary time is as nothing compared to the millions of years of which the globe shows a record. The whole process of deposition of metallic minerals and their re-working into pay-ore has been accomplished in a few geologic moments.*

Secondly, all the profitable ore deposits of Mexico are found in a thin skin of surface material approximately 2000 ft. in depth; less than half a mile or roughly one-twenty-thousandth part of the earth's diameter. Geologically speaking, therefore, ore deposition in Mexico is most emphatically a surficial operation; and from a broad point of view, the whole series of operations, primary deposition, recurrent movement of the walls, re-deposition and enrichment, is made up of chemical processes, chiefly oxidizing, which take place wholly in the extreme outer skin of the earth, practically in permanent contact with oxidation influences.

If we conceive of a ball 20,000 ft. in diameter; that is, nearly as high as the highest mountain on earth; then the thickness of one foot on the surface of this ball represents closely the relation of the thickness of the ore-horizon to the whole mass of the globe.

*This point has been emphasized by T. A. Rickard, 'Persistence of Ore in Depth'. Trans. Inst. M. & M., London. Vol. XXIV, p. 36.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

FREIGHT ON BULLION SHIPMENTS REDUCED.

Bullion rates on shipments from Arizona smelters have dropped \$2 per ton, it was announced last week by the traffic departments of the Southern Pacific and Arizona Eastern railroads. The rates apply only to shipments on Morgan line ships to New York and Eastern ports, via Galveston. The all-railroad rate is \$22.10. By Morgan Line Southern Pacific steamship the rate is \$20 per ton.

TUCSON.—The main orebody of the old Yuma mine, 14 miles north-west of Tucson, that had been lost on the 200-ft. level, has been re-discovered on the 300-ft. level in a cross-cut into the foot-wall from the shaft. This cross-cut is being continued; the ore is exposed to a width of 5 ft., an average sample assaying in lead, copper, gold, and silver, \$82.50 per ton. The main lode is from 12 to 20 ft. in width, and developed by open-cuts and shaft for a distance of 4500 ft. The Yuma is a famous old mine, located in 1872. Equipment consists of a 200-ton concentrating-mill, mining-machinery, electric-light system, store, and dwelling-houses.

MIAMI.—Seven thousand five hundred pounds of 20% T.N.T. was exploded on September 29 on the new Superior highway, to dislodge about 8000 yd. of rock that tumbled from the side of the mountain down into the canyon. The old Cowboy property, known as the McGraw gold mine, has been sold to a syndicate of Michigan men for \$60,000 and one-half of the ore now on the dump.

PEARCE.—The 150-ton mill on the Middlemarch property, near Pearce, has been temporarily shut down on account of shortage of water. Work is now under way to develop more water. After exhaustive tests, a method has been perfected for separating zinc from copper concentrates by flotation.

GLOBE.—A suit for damages, amounting to \$35,000, has been filed in the superior court at Globe by Mrs. Clyde M. Ney, widow of Clyde M. Ney, former employee of the Old Dominion Copper Co. At the time of his death, Mr. Ney was an engineer in the service of this company, and while working on the 1800-ft. level was killed as the result of a blast in a working place which he had entered. At a coroner's inquest the following day, no responsibility for the death was fixed.

BISBEE-WARREN DISTRICT.—Thirty thousand dollars in gold coin was paid out on September 21 by the Bank of Bisbee to miners of the Copper Queen Co., this being the first pay-day in three years that the miners received their

pay in the yellow metal instead of by a piece of paper. A serious shortage of fuel threatens the Warren district and has resulted in the shutting down of the Boras and Nighthawk leasing companies, the Higgins Mining Co., and the Denn mill. All these companies are dependent for power on the Bisbee Improvement Co. which has been forced to cut their power to conserve fuel for the city lights and gas plant. Relief of the shortage depends on transportation. The bigger mining companies are not worried by the shortage. Fuel-oil used in the Warren district, at present, is being shipped by boat from Mexico to Galveston, and it is feared the Gulf storms may further delay shipments. All records for speed were broken in sinking the new ventilation shaft in the Briggs division of the Calumet & Arizona property. The total depth of the shaft, to be known as the Oakland, is 827 ft. The best advance was made during August when the shaft was sunk 281.5 ft. The object of this new shaft is to remove all smoke and gases from the large sulphide area in the Briggs division. During the latter part of March of this year, a fire broke out in the stoping area, between the 1300 and 1400-ft. levels. This was temporarily extinguished, but a month later broke out again, and the management decided to sink the new ventilating shaft, to avoid a repetition of these outbreaks. Operations of the Western Ore Purchasing Co. of Utah and Nevada, purchasers and samplers of ores direct from the prospectors, will, it is said, be extended to Arizona within sixty days by the erection of two plants of 4000 tons per month capacity, one of which will be at Tucson and the other at Douglas.

PATAGONIA.—The Blue Nose has just completed the delivery of a carload of carbonate ore. The Flux mine is working at the 260-ft. level in a vein of milling-ore 25 ft. wide.

JEROME DISTRICT.—Recently an ore-chute between the 1350 and 1200-ft. levels at the United Verde mine caught fire from the blast of an explosion. The fire was not of great extent, but for a short time the smoke was oppressive and threatened to overcome the men who rushed down from the change-room and extinguished the flames before any considerable damage was done. The Western Chemical Co. has commenced operations at the sodium sulphide deposit. It is reported that dynamite has been found unsatisfactory as an agency for loosening the sulphate and therefore all blasting will be done with black powder. Haulage will probably be done by contract and approximately ten 5-ton machines will be needed.

COLORADO

RICH ORE IN THE MAYBELLE.

CRIPPLE CREEK.—Drilling has been resumed at the formation test in the north end of the district, the bit having been recovered by reaming. The test is now below the 2000-ft. point and important developments are expected in the next few days. The core showed nothing but Pike's Peak granite to a depth of 1084 ft., at which point the drill passed into heavily mineralized rock showing pyrite and fluorite. This continued for 16 ft. At 1100 ft. granite was again found but pyrite was present. At 1196 ft. the drill dropped 5 ft. into an open crevice. Water used for drilling disappeared. The hole was cemented back for 20 ft. and when drilling was resumed the bit fitchered and this caused the long delay. The Gold Bond property, on the south-eastern slope of Gold hill, has been leased. An air-line has been connected to the compressor at the Dig Gold company's shaft on the Alpha & Omega nearby and development is progressing. Tetrahedrite containing a large amount of silver is reported by lessees at the Blue Flag mine, Bull hill, owned by the Buckeye Mining Co.

SILVERTON.—Rich ore has been found at the Maybelle mine in Poughkeepsie gulch, idle 20 years. The property, owned by Mrs. Charles Carlstrom of Silverton, is under lease to Fred Jacobs of Red Mountain, who last week shipped a car of gold-silver ore estimated at better than \$500 per ton. Mines are working short handed on account of claim owners, having unpatented properties, leaving to perform assessment work.

LEADVILLE.—A compressor and other equipment is being installed at the Bard, Wall Street, and Gnome properties for Fred Johnson and associate lessees. Both Wall Street and Gnome already produce oxide ores, lead sulphates, and gold ore.

CAMP BIRD.—From quarterly reports of the Camp Bird, Ltd., to June 30 it appears that the eastern workings have not so far revealed other than short stretches of commercial ore. Work in this direction has, therefore, been suspended and all activities transferred to the west end, working from the tunnel-level. The vein carries all the characteristics except that to date it has been very lean.

MICHIGAN

POWDERED-COAL FIRING IS BEING ADOPTED AT CALUMET.

CALUMET.—The Stanton mines, Wolverine and Mohawk, are sold well ahead and a market could be found readily for a greater output if the men were available. In fact, were it possible to obtain miners and trammers in sufficient numbers, the mines would be operated to capacity. In this connection, the arrival of Italian immigrants at Mohawk is encouraging. More are expected. The coal situation no longer appears to be troubling these properties. Notwithstanding the oft predicted end of Wolverine, the mine goes along producing copper and while the yield and output become smaller each year the actual end of the property is far distant, even if opera-

tions are conducted on no other than the Kearsarge amygdaloid. A number of the workings in the upper levels will yield considerable quantities of metal before the shaft pillars are removed for there are long stretches of ground that have only been touched, so far as stoping is concerned. On the 14th level there is a block of ground 700 ft. long, between No. 3 and No. 1 shafts, that has been opened little more than by a drift. On other upper levels there are similar stretches in reserve. Operations at present are confined to lower levels, and a long time will elapse before it will be necessary to begin removing the ground in the upper openings. By that time it is expected that conditions will have improved sufficiently to warrant the exploration of ground east and west of the amygdaloid formation.

Mining men here attach considerable importance to the mechanical tramping-devices and scrapers in Calumet & Hecla conglomerate-shafts and there is a hope that the greater part of the difficulties that have arisen in past years from the shortage of trammers will be eliminated. Only three of the shovels are in use but there is a likelihood that they will be installed throughout the mine. It is stated unofficially that the device has measured up to the most sanguine expectations and that a complete equipment of them would enable the company to make a material increase in production with the present force of miners. Three men operating a shovel can do as much work as eight men by hand shoveling.

Steel is expected to arrive for Calumet & Hecla's new flotation-unit within two weeks, but uncertainties in delivery may prevent the completion of the work before spring. At the Tamarack reclamation plant, preliminary work is under way. The old structures have been dismantled and the machinery removed. The concrete foundations for the new buildings and machinery will be put in this fall so it will be possible to erect the tanks, tables, and grinding-machines by spring if the manufacturers can make delivery. This plant will be more than half as large as that of the Calumet & Hecla.

The Michigan smelter has started driving piles for the foundation of a new building. The new structure is to house a coal-grinding plant and is being built to supply the coal-dust burners at the smelter furnaces. The coal-dust firing system is new to the Michigan copper country although it has been used in Western smelters with much success. The machinery for the plant has been ordered but it is not likely that the new system, which will work a considerable saving, can be completed and in working order before spring. The 13th level drift at Gratiot, 826 ft. from the shaft, is rapidly approaching the Mohawk No. 1 shaft boundary. The ground is described as satisfactory and stretches of it have revealed even higher value than was opened in the Seneca. The showing bears out predictions of mining men that have been in touch with Mohawk, that the best ground would be opened near the northern boundary of Mohawk. The fifth level plat at Seneca is practically complete and preparations are being made to proceed with the concreting of the shaft and the laying of the skip rails. When these pre-

liminaries are finished drifting will be begun. The best showing in the shaft at present is in the third level north, which has reached a length of 710 ft. from the shaft. The ore on the fourth level, 630 ft. from the shaft, is fair. In the fourth level south about 10 ft. from the Ahmeek boundary, the quality is poor. This drift is 376 ft. from the shaft.

Hancock is building a concrete reservoir on the 53rd level to prevent the water from overflowing into the new openings. If the price of coal continues high it may be decided to suspend pumping and the concrete dam will take care of the water until operations are resumed. In some quarters it is rumored that Hancock will dispose of its holdings to Quincy, but there is no confirmation of the report.

Superior reports a slight increase in tonnage for September, with a total of 1700 tons to date. This ore is com-

VIRGINIA CITY.—During last week 166 tons of ore assaying \$17.80 was mined in the winze being sunk from the 2150-ft. level of the Consolidated Virginia. The ore has raked out of the winze, but a drift from the bottom has entered the shoot. During the week 400 tons of \$22.50 ore was produced from all parts of the mine. The Gold Hill miners are still on strike.

TULE CANYON.—A drift being driven west on the 200-ft. level of the Silver Hills is expected to enter the ore-shoot within 10 ft. The company has again changed superintendents and Edward Orr, formerly with the Goldfield Consolidated, is now in charge. This change followed rumors of unnecessarily high operating-cost. The Silver Hills and a company driving a tunnel several miles north of the Ingalls are doing the only work in the canyon.

CACTUS.—A carload of ore assaying \$75 to \$100 has

SIMON SILVER-LEAD MINE, NEVADA

ing from exploratory openings in No. 1 shaft, chiefly from the elevation of the 31st level. The best ground in this shaft was opened 700 ft. south on the 31st level, nearly a half mile from the shaft.

Ahmeek's tonnage shows a steady improvement with daily shipments of nearly 3000 tons. This is the best that has been reported for nearly a year and if more miners were available it would be possible to make further increases. Kearsarge reports a slightly smaller daily average, 1500 tons, while Osceola's daily tonnage has dropped to 250.

NEVADA

A SELECTIVE-FLOTATION MILL WILL BE BUILT AT THE SIMON SILVER-LEAD MINE.

DIVIDE.—It is reported that the vein cut recently on the 700-ft. level of the Gold Zone assays \$40 for a width of 25 ft. and that 10 ft. of this width assays \$150 in gold, according to mine-car samples. The station on the 1000-ft. level of the Tonopah Divide has been timbered and the sump is nearly completed. The Kernick shaft has passed the 900-ft. point.

been shipped by the Cactus Nevada to the Development mill at Goldfield. The force of miners has been reduced due to difficulty the company is having in raising money.

RAND.—The Gold Pen company, which several months ago started milling ore in a 20-ton plant, after statements published in Nevada newspapers had announced important high-grade orebodies in the mine, is now being sued by machinery and mercantile companies. The district boomed early in this year on the strength of reports from the Gold Pen, Nevada Rand, and Mimms. The first was said at that time to contain, among other orebodies, one in which there was 400 tons of \$500 ore.

TONOPAH.—The Tonopah Mining Co. has stopped work in the Blue River placer field in Colorado and the project has been abandoned. A five-sixths interest was acquired eight years ago for \$375,000, but the venture has proved unprofitable since 1915.

COMO.—A clean-up is being made at the 100-ton mill of the Como and when this has been completed the mine and mill will be closed for the winter. The Como is a silver-gold mine that has been producing at a rate of \$200,000 yearly and the reason given by Gurney Gordon,

manager, for the closing is the high cost of supplies and a scarcity of miners. The mill has been treating \$12 ore with a recovery of 98% of the gold and 90% of the silver.

EUREKA.—The stockholders of the Eureka Croesus, at the annual meeting held in Eureka, voted to increase the capitalization from \$1,500,000 to \$3,000,000. The annual report is to be issued in a few days.

ARROWHEAD.—The Arrowhead continues to ship to Tonopah at a rate of 75 tons per month. The ore assays \$100 to \$125 per ton. The company is planning to increase the output to 100 tons monthly by using another truck and improving the road to Tonopah.

GOLDFIELD.—The Grandma has levied assessment No. 7, at the rate of 1c. per share, delinquent November 1. The shaft, which is being sunk from 830 ft., is now 870 ft. deep and it is expected that at 1000 ft. a cross-cut will be driven to the east-dipping shaft, although the depth at which the cross-cut will be driven will depend on the depth at which favorable conditions are found in the shaft. The company has arranged to secure a lease on a part of the Kewanas, adjoining the Grandma on the west, so that prospecting for the shale-latite contact may be continued into the Kewanas if it is not found in the Grandma claim. The winze sunk on the west-dipping shale at 815 ft. exposed ore assaying as high as \$17.50 and from a raise near the winze assays of \$40 were secured. The winze was sunk 75 ft. and at this depth the company drifted 125 ft. west. All of this work showed the latite and shale to be highly metamorphosed and the ore was found erratic in width and value. The west-dipping shale also will be explored at greater depth. The winze from the 910-ft. level of the Spearhead has been sunk 250 ft. The vein, 8 ft. wide at this depth, is low-grade. The vein walls have been alaskite since sinking was started and the winze may be continued to 750 or 1000 ft. The Development mill will be closed for the winter and preparations are being made for the final clean-up. The last shipment was made to the mill on September 29. John P. Sweeney has secured in the district court a judgment against the Conqueror Consolidated Mining Co. for \$5411.50, alleged to be due for salary as manager and for money expended. The Conqueror, owning ground in the northern part of the district, has been inactive for years.

MINA.—Mill construction will begin shortly at the Simon Silver-Lead mine, 22 miles east of this town. The mill-site selected lies on the west slope of a steep ridge, across a deep gulch from the present 565-ft. incline shaft and south of the site of the main three-compartment shaft. Ore will be delivered by gravity from both shafts to the mill storage-bins. The ore contains silver, lead, and zinc; the process to be employed is selective flotation; by regulating the oil-feed in the cells, separate lead-silver and zinc-silver concentrates will be produced. After crushing, the oversize from a trommel passes through rolls to a Hardinge ball-mill and then to a Dorr classifier, the coarse going to a small ball-mill and then returning to the classifier. The pulp then passes to a series of 26 flotation-cells of the Minerals Separation

type. Here, by the use of cleaner-cells and re-floating the product from certain cells, the separation of lead and zinc is effected and the lead-silver and zinc-silver concentrates pass to separate units of the filter plant. Semi-Diesel engines, generating 250 hp., will supply power for the mill. It is said that this process ensures a zinc recovery worth \$3.50 per ton and that it will convert the usual penalty on this metal into an important revenue. Development in the mine has progressed to the seventh level, at a vertical depth of 565 ft. Carbonate ore, some of exceedingly high grade, was found on upper levels and sulphide ore appeared at 200 ft., but the sulphide level is placed at 230 ft., for purposes of estimating reserves. Before ore had been found beyond the east and west faults, the company's engineers estimated 400,000 tons between 230 and 400 ft. depth, that would net \$7 per ton.

PIOCHE.—The Nevada Horn Silver property, 23 miles north-west from here, will shortly be equipped with a 30-ton cyanide plant. The property has recently been taken over by a new company. John L. Whipple is president. A. E. Place, secretary-treasurer, is connected with the Zinc Chemical Co., Inc., a company now erecting a plant at Los Angeles for the manufacture of zinc oxide. The company owns six patented claims and an ample water-supply. The ore is hard and contains no slime-forming elements, such as clay, which facilitates the treatment proposed in the preliminary 30-ton plant. It is stated that about 150,000 tons of ore available for treatment has been developed. During the week ending September 23, the Prince Consolidated shipped 1330 tons of ore; the Virginia Louise, 780; the Combined Metals, 210; the Black Metals, 100; the Bristol Silver Mines, 95; and the Magnolia mine, 40; making a total of 2555 tons. The Belle Helen silver mine 50 miles east of Tonopah has been sold by its owner, T. T. Cornforth, to Los Angeles and Goldfield parties. A large cash payment was made.

NEW MEXICO

MEETING OF STATE CHAPTER OF THE AMERICAN MINING CONGRESS.

SILVER CITY.—Mining men of New Mexico met in Silver City, Monday, October 4, for the purpose of completing the organization of a State chapter of the American Mining Congress. Assistance will be rendered the meeting by Herbert Wilson Smith, Chief of the War Minerals Division of the A. M. C. of Washington, D. C., and John T. Burns, assistant secretary of the same organization.

PINOS ALTOS.—At the Silver Reef group, situated about two miles east of the Silver Cell, the 65-ft. shaft is being unwatered and deepened. The mine was worked more than 30 years ago by a Mr. Bennett and it is said that from this 65-ft. shaft 10 tons of ore were shipped that averaged \$508 per ton. The vein is narrow but the ore is of high value and shows no lead or zinc.

GRANT COUNTY.—It is reported that through the efforts of C. W. Mitchell, manager for the Montclair Mining Co., owning the Cora Miller mine on the Mangas, a group of New York capitalists has become interested in the mining possibilities of Grant county. One of the

properties being examined is the Long Hope, situated in the Fleming district, less than five miles north-west of Silver City. The ore contains silver chloride and silver sulphide and is reported to assay from 25 to 100 oz. per ton.

SIERRA COUNTY.—Plans are under way for the installation of a chloride roasting and leaching-plant at the mines of the Moffitt Mines Co., on North Percha, Kingston district.

UTAH

UTAH SULPHUR CORPORATION'S LEACHING-PLANT NEARLY COMPLETED.

SALT LAKE CITY.—During the week ending September 25, the Utah Ore Sampling Co. released from its Murray sampling-mill 87 cars of ore from Utah mines, 13 from Nevada, 3 from California, 3 from Montana, and 1 from Idaho. At its Tintic mill the company released 35 cars from Utah mines.

ALTA. During September shipments from the South Hecla mine totaled about 25 cars, according to George H. Watson, the manager. Development and production has been retarded in recent months by a serious shortage of labor. The Albion Consolidated drain and transportation tunnel, which is being driven to open in depth rich ore-shoots mined in the upper levels, is going ahead at the rate of 125 ft. per month.

The Columbus-Rexall property was never in better shape than at present, according to M. R. Evans, president of the company. From September 1 to 24 the company shipped 8 carloads of ore averaging more than \$50 per ton. If men were available the output could be doubled. The company has laid in sufficient stores to continue operations throughout the winter. The first snow of the season fell on September 24, but weather conditions were probably such that shipments can be made for several weeks yet.

SANTAQUIN.—At the present time the Union Chief Mining Co. is prospecting a mineralized limestone that is cut by a number of ore-bearing fissures, according to the general manager, G. L. Bemis. From this development work five cars of good shipping lead-silver ore have been taken and are now awaiting transportation. On account of the large amount of road construction and work in the Tintic district, men and teams are so scarce that the company is unable to secure teams for hauling ore.

EUREKA.—During the week ending September 25, the Chief Consolidated shipped 32 cars of ore; Tintic Standard, 28; Mammoth, 31; Dragon, 13; Eagle & Blue Bell, 11; Iron King, 5; Iron Blossom, 4; Grand Central, 4; Swinsea, 3; Centennial-Eureka, 3; Bullion Beck, 3; Colorado, 1; Victoria, 1; Gemini, 1; Griggs-Huish, 1; Yankee, 1; a total of 143 cars. Fearing that the railroad companies are preparing to appeal from the decision of the State Public Utilities Commission prohibiting an advance in freight-rates on intra-state shipments of ore and coal, local mining men are not only preparing to oppose such an act, but are advocating a movement to secure reductions in existing rates, which they contend are crippling

the mining industry. The mine owners are preparing to meet the railroads in any fight which may be brought about for the purpose of increasing freight-rates on ore. It is a question of life or death for some of the mining companies, and it does not seem reasonable to suppose that the Interstate Commerce Commission will interfere. It is claimed that the rates on ore from Utah mines are now higher than those existing outside the State, and the same may be said of the rates on coal.

Directors of the Lehi-Tintic property have decided to sink a shaft, according to Charles Zabriskie, president of the company. Orders have been placed for the necessary hoisting and other equipment. The shaft will be sunk from the lower level to a depth of 500 ft. No deep work has been done; the prospecting consists of adits.

Work has been resumed at the property of the Scran-

HOSTOTIPAQUILLO DISTRICT

ton Mining Co. after a shut-down of more than a month. When the increased freight-rates went into effect on August 26, shipments were suspended. The ore is a zinc-lead product and is being shipped now to Colorado, the burden of the increased freight-rate being borne by the purchasers. For some time past this property has been worked by James Wade and associates of Salt Lake City, who, in turn, have sub-let parts of the mine to other lessees. About two carloads per week are now being shipped from the property.

BEAVER COUNTY.—M. P. Morrissey, president of the Utah Sulphur Corporation, says that the company's new leaching-plant, which will have a capacity of 250 tons per day, will be completed and put in commission by November 1. In order that the work might be rushed on this plant, the company stopped taking orders about mid-summer, operating the retorts and sub-limer only to such an extent as would care for orders already on the books. With the leaching-plant in commission, the company expects its output of sulphur to be not less than 350 tons per day. Mr. Morrissey states that the leaching-plant

will enable the company to produce sulphur at a smaller cost than the present methods. The sub-limer is used for making 'flowers of sulphur'. While in Chicago recently Mr. Morrissey made arrangements for entering an entirely new line, that of making a fertilizer by combining sulphur and phosphate rock. The Utah Sulphur Corporation will erect a plant in Chicago with a capacity of 150 tons of fertilizer per day, and it is believed that it will be in operation by midwinter.

PARK CITY.—At the Keystone property, two levels are being extended and three raises are being made. In the face of the K-K-3 level, exceptionally good ore is being mined; assays showing from 35 to 40% lead and about 15 oz. silver. At the present time the property is shipping only the ore taken out in development. Forty men are now employed, and ample stores are being put in to permit work throughout the winter. The company has secured the old Kearns-Keith mill, which is being put into shape for handling the low-grade ore.

At the Ontario Silver Mining Co.'s property, which is under the same management as the Keystone, it is stated that some of the richest silver ore ever discovered has been found on the 2000-ft. level, the deepest in the mine. A break in the machinery prevented the handling of water that came in at about the time the ore was found and the company immediately ordered a new pump, which has arrived at the property and is now being installed.

A rich showing has been developed north-east of the O'Brien stope in the Silver King Coalition mine, according to the manager, M. J. Dailey. The strike is on the 1100-ft. level and is important because it was discovered in virgin territory. The strike made some weeks ago between the 1200 and 1250-ft. levels continues to show improvement. These two developments are the most important made in the Coalition property in recent years.

BRITISH COLUMBIA

A POSSIBILITY THAT GOVERNMENT FUEL-CONTROL WILL BE RESTORED.

TRAIL.—The ore receipts at the smelter for the week ended September 21 amounted to 8810 tons, the Consolidated M. & S. Co. mines contributing 7846 tons toward the total. The other shippers were: Bluebell, Riondel, 175 tons; Josie, Rossland, 223; Mandy, Le Pas, 65; Monarch, Field, 45; North Star, Kimberley, 224; Ruth, Cedar Creek, 108; Silver Bear, Zpicky, 28; Skyline, Cedar Creek, 37; Velvet, Rossland, 31; and Texas Yankee Girl, Ymir, 29.

Rube and Carl Laib, owners of the Spokane group in the Bayonne district near Nelson, are seeking government aid in the construction of a 150-mile pack-trail down Canyon creek to Kootenay lake. Rube Laib states that such a trail would provide means for shipping ore from the mines economically and would put the properties on a working basis. Ore from the Spokane property to Trail has been carried up a steep pass to the headwaters of Sheep creek and out by way of Salmo. The cost

of transportation from the mine to Salmo has been \$45 per ton.

EDGEWOOD, ARROW LAKES.—Considerable activity is reported in the Lightning Peak district, and undoubtedly this district would attract a good deal more attention but for the bad state of transportation. E. H. McDonald has been examining a number of properties recently in the interest of Billings, Montana, people. A one-foot vein, said to carry gold and silver in paying quantities, has been cut by the main tunnel on the Rampallo group at a distance of 40 ft. from the portal. The tunnel is being driven to cut a body of ore which down to a depth of 20 ft. gave average returns of \$10 in gold and 250 oz. of silver per ton. The tunnel should cut this orebody at a depth of 150 ft. after it has been driven for another 260 ft. Rendels & Co. is sacking high-grade at its Waterloo claim, and expects to have 800 sacks filled for transportation over the winter snow. W. J. Banting has struck a foot stringer of solid galena in a six-foot vein of milling-ore at the Killarney group.

VANCOUVER.—The Geological Survey men are returning from their summer's field work. R. W. Brock, of the University of British Columbia, reports promising indications of silver-lead ores and some copper ores in the inner flank of the Coast range, west of Burns lake. He describes the country as exceedingly rugged and states that little prospecting has been done. Victor Dolmage, who has been on the west coast of Vancouver island during the summer, reports the occurrence of mercury ores at Sechart, Barclay sound, but doubts whether either grade or quantity is commercial. He reports important deposits of copper ores and magnetites at Nootka sound, where considerable work is being done on them. Officials of the Granby Consolidated M. S. & P. Co. state that by sending the company's blister-copper through the Panama Canal, instead of by rail, not only is the cost reduced by nearly half, but the time of transportation from Anyox to Long Island, New York, will be reduced from 60 days to 45 days.

NELSON.—A galena property has been located at Nakusp on the Arrow lakes. The claim is known as the Lucky Rose and is especially interesting for the reason that this section has not hitherto been considered as possessing mineral possibilities. Already a lode has been uncovered for 300 ft. and assays of 49 oz. silver and \$1.80 in gold are reported.

KASLO.—John Keen, speaker for the Provincial legislature, has just returned from a trip through the Lardeau district. He visited the Lardo, Trout Lake, Ferguson, and other points. Mining, he says, is rather quiet. The Triune, True Fissure, and other claims look well, while the lessees on the Silver Cup and Nettie L. have made good progress and have ore ready to ship. The Gold Cure is promising. He said that the labor situation was showing marked improvement, men were going back to the camps seeking employment and the indications are that in a short time the trouble which has been experienced during the past few months will be settled.

GREENWOOD.—The Lightning Peak mining section is

being opened by the construction of a trail, under the terms of the Mineral Survey and Development Act. The Provincial government has been busy on this for a large part of the past season, and the work now is reported to be practically completed. Lightning Peak has an elevation of about 7500 ft. In that locality are situated

Zone where it crosses the Jordan river into the Gabbro group. The open-cuts referred to have established a width of 5 to 25 ft. of mineralized material having a length of between 300 and 400 ft. There is a considerable body averaging 3% copper or better, which is the best surface showing yet found in the Jordan River sec-

a number of mining properties, among which is the Waterloo, that give promise of developing into important mines. On the completion of the trail it will be possible to make the trip with pack-horses from Greenwood to the peak in four days.

VICTORIA.—A small force of men has been employed since last March on the Gabbro Copper Mines, Ltd., situated at Jordan River, Vancouver island. Several large open-cuts have been made to ascertain the grade and size of the orebodies. Some good ore has been taken from a tunnel driven on Sinn Fein creek, but the most promising showings were found on the Sunlock Cave

tion. The orebodies on the Gabbro group are in basalts of Eocene age, which have been intruded by a stock of gabbro. There has been much shearing of the basalts, due probably in part to the shrinkage of the gabbro mass when cooling, and also to regional stresses. There has also been some shearing and ore deposition in the gabbro. Continuity of the ore at depth in these shear-zones is shown by the tunnels on the adjoining Sunlock property, which indicate a vertical depth of over 500 ft. The Sunlock is one of the very few mines in this Province that has had no serious set-back since the beginning of mining operations on it in 1917.

It appears from Ottawa dispatches that there is a probability that the fuel-control system in force during the War will be re-introduced shortly. Under this system each Province had its own commission, whose duty it was to see that there was a fair distribution of the available supply of coal. The Railway Board, under whose jurisdiction the fuel control is placed, has not definitely decided to restore the regulation as yet, but promises that definite announcement will be made in a few days. Whether this proposal will affect British Columbia is a question.

ONTARIO

OIL-FLOTATION OF TAILING IN COBALT LAKE IS A SUCCESS.

PORCUPINE.—While hitherto most of the development on the Hollinger Consolidated has been done above the 425-ft. level, preparations are now being made for opening up the lower levels on an extensive scale. A winze was sunk to a depth of 1250 ft. some years ago to prove the downward continuation of the ore, and this having been done work was stopped. The lower workings are now being dewatered and a raise will be made from the 1250-ft. level to the central shaft. The company has declared another one per cent dividend, being the third consecutive four-weekly payment. The Dome Mines is treating about 1000 tons of ore per day, working under the disadvantage of a shortage of labor. The ore taken from the stopes is considerably richer than was estimated. It is stated that large quantities, the gold content of which was placed at about \$4 per ton, are actually yielding upward of \$6. The Vipond-North Thompson is being re-opened, operations being in charge of W. S. Gowans, formerly of the Dome Mines staff. J. B. McArthur, a prominent British mining engineer, and Major J. McIntosh Bell are acting in an advisory capacity.

KIRKLAND LAKE.—Conrad E. Weltlaufer, president of the Orr Gold Mines, has issued a statement to the shareholders announcing that funds have been procured and the debt of the company paid. J. C. Houston has been engaged as engineer. A vein supposed to be No. 1 vein of the Lake Shore, has been cut and is found to be 5 ft. wide and well mineralized. Reference is made to the proposed consolidation of the Orr with "two operating companies" which will come up for consideration at the annual meeting on September 30.

SKEAD TOWNSHIP.—There is considerable activity in this district and many new properties are being developed. At the Fidelity, an 8-ft. vein showing free gold was uncovered in stripping a schisted porphyry dike. The shaft on the originally discovered vein is being sunk to the 100-ft. level. The Crawford-Skead is putting down a shaft by hand-steel on a vein carrying gold over a width of 8 ft. Several other veins have been found by stripping and trenching. The Skead Gold Mining Co. has a group of claims on the east shore of St. Anthony lake, which it is preparing to develop having constructed four miles of road to provide transportation. On the Meany claims in north-east Skead, where an important find was made this summer, camps are being erected. The Manley claims,

which attracted attention to this field a year ago on account of a spectacular discovery, are again being worked by Walter Manley and associates.

COBALT.—The mines in the Cobalt district are operating with a shortage of about 10% of the labor required. Great difficulty is being experienced in procuring shovellers, and skilled men are being employed on this work. The cost of producing silver is likely to increase during the closing quarter of the year owing to the shortage of labor as well as to an increase in freight-rates. Dispatches which carry the information that the price of cotton, leather, and machinery has commenced to decrease convey the hope that these favorable factors may offset the adverse influences.

On October 30 the Coniagas Mines will finish a favorable fiscal year. An average of 500 tons of ore is being treated daily, 100 tons of which is treated by cyanidation in the Buffalo mill of the Mining corporation. The mill heading averages from 8 to 10 oz. per ton, as compared with 13.07 oz. during the preceding year. Arrangements are being made to increase the amount treated to 600 tons daily, and it is believed that output can be well maintained during the coming year.

Net earnings at the McKinley-Darragh are slightly under dividend requirements at the rate of 3% quarterly. The company has a surplus of about \$365,000 and it is understood the deficit in net earnings below dividend requirements of \$67,000 every three months may be drawn from the surplus, and the current rate of disbursement maintained for a considerable period. At a depth of 350 ft. on the Keeley Silver Mines, in South Lorrain, vein No. 9 has been cut, and shows a width of 14 in. containing from 200 to 400 oz. silver per ton. The cross-cut is being driven toward the Beaver Lake vein, which is believed to lie 35 ft. farther north. The 20-stamp mill is expected to be ready for operation by the end of November. Twelve sacks of ore containing 2000 oz. of silver per ton has been cobbled from the dumps on the Silver Bullion property at Leroy Lake in the Gowganda district. The installation of a small mining plant has been completed and tenders are being called for several hundred feet of underground work.

The La Rose is working its different properties steadily. On the University the ore-shoot has been followed up for 175 ft. and the drift is still in ore. It is for the most part good milling-ore with patches of high-grade. The Princess property is the most important producer. Considerable ore is being taken out along the McKinley-Darragh boundary. The original La Rose claim continues to yield good milling-ore. A meeting of the shareholders of the Temiskaming has been called for October 7 to consider the proposal to purchase a half interest in the Blue Diamond Coal Mines and the Canadian Coalfields, Ltd., in Alberta, lately secured by the McIntyre of Porcupine.

ELK LAKE.—The Reeves-Dobie has gone into the hands of a receiver and 213 bags of concentrate in transit have been seized to satisfy a judgment against the company for wages. Silver has been found on the Regent property recently opened in James township.

CALIFORNIA

Amador County.—At the old Eureka mine (Hetty Green's old property) development work under way on the 3500-ft. level has uncovered rock of better character than any found thus far on other levels since the re-opening of the property. An ore strike of great importance to the Plymouth Consolidated Mining Co. has been made. A 12-ft. vein of rock assaying from \$10 to \$15 per ton has been struck on the 2050-ft. level, and development work so far done on it indicates its likelihood to yield well for some time to come. The find is particularly encouraging at this time, when the mine's ore-reserves have become limited.

Calaveras County.—Ray Lantson and A. S. Kingsberry, employees of the California Mining Co., lost their lives in a mine fire. The fire broke out in the main shaft September 30 and destroyed the surface equipment. Lantson volunteered to go into the mine by another shaft and turn on the pumps. He did not return and A. L. Riggs and Kingsberry went below to rescue him. Kingsberry was also overcome but Riggs escaped. It is reported that the men wore army masks which are not adapted for use against mine-fire gases. The rescue trucks arrived too late.

Placer County.—For the third time in her history, Iowa Hill, one of the old hydraulic mining camps of Superior, California, has been swept by a disastrous fire, the loss being estimated at between \$35,000 and \$40,000. Twenty-six buildings were destroyed, including the school-house, a hotel, and the Methodist Church. Not more than seven houses escaped the flames.

Shasta County.—The Arps Mining Co., which has operated the Arps group of copper mines near Copper City for four or five years, has deeded the mines back to the original owners, R. M. Seltzer, Anton Jaegel, William Arps, and Mrs. Mary Ruoff. The Mountain Copper Co.'s new roller crushing-plant near the Hornet mine above Keswick will be ready to begin crushing about October 15. This plant is designed for the fine crushing of pyrite from the Hornet mine and will have a capacity of 600 tons per day. Unfortunately the copper situation is still unfavorable and the Mountain Copper Co.'s Iron Mountain copper mine, near the Hornet, remains closed.

IDAHO

Coeur d'Alene.—The Federal Mining & Smelting Co., owning several claims in the Coeur d'Alene, has let a contract for sinking an additional 200 ft. on the Morning mine, giving it a depth of 1400 ft. below the main working tunnel. With the completion of the contract a cross-cut will be run to the main vein and the body of ore which has been opened on the 1200-ft. level will be developed on the 1400-ft. level. The lower levels of the Morning mine are showing the best ore found in the property for some time. Development of the Idaho Northern property, five miles east of Murray, is to be resumed after many months of idleness, and a compressor has been delivered to the property for the purpose of running a 1600-ft. cross-cut adit which will open the ore at a depth of 1300 to 1400 ft. An adit already has been run in the property for a distance of 370 ft. and work has been completed which opens two large veins at a depth of 300 or 400 ft. One of the veins carries lead, silver, gold, and cop-

per to a value of \$50 per ton. Buildings have been started on the property for men and equipment.

MONTANA

Butte.—The situation in the Butte camp continues unusually quiet, but the increase in the average of working shifts from 33% to 45% of normal within the last month would indicate a slight improvement. All officials are confident that demand for copper will increase after the fall elections are out of the way. At the Davis-Daly an excellent 25-ft. orebody continues to hold up on the 2700-ft. level. This is the same body which with a 14-ft. showing was drifted on for several months. The ore is all first class 5% or better and the vein is the third distinct orebody encountered on the 2700-ft. level. At the Hibernia of the Davis-Daly cross-cutting is in progress on the 600-ft. level following completion of a station at this level. At the Boston-Montana mine work will be started soon on erection of a flotation plant. Drifting is in progress on several veins on the 300-ft. level. Shipments from the Emma mine of the Butte Copper & Zinc Co. for August amounted to 8000 tons of manganese ore and 4000 tons of zinc ore, with the manganese running 37½% and the latter averaging 15% zinc, 6 oz. silver, and 5% lead, according to the 'Boston News Bureau'. Of the manganese tonnage, two-thirds is being shipped to the ferro-manganese plant of the Anaconda Copper Mining Co. at Great Falls, which is operating the Emma under a long-term lease on a 50-50 profit-sharing basis. The balance of the manganese is being shipped to the Carnegie steel plants in the Pittsburgh district.

Great Falls.—Petition of State Attorney General S. C. Ford for an injunction restraining the Cascade Silver Mines & Mills Co. from dumping the tailing from its Neihart mill into Belt creek, in Cascade county, failed in the Great Falls district court. In an order issued today by Judge H. H. Ewing the injunction was denied. The company was awarded costs in connection with the suit and the attorney general's action dismissed.

NEVADA

Virginia City.—The Gold Hill mine operators have issued a statement to the effect that they do not consider the Gold Hill Miners' Union responsible, and decline to recognize it or consider its demands. The operators claim the union is composed of only twenty men and that the notices branding the camp and operators as unfair were posted by authority of ten men. The operators further assert the United Comstock Co. alone employs 160 men normally, and has 70 men at work at present. It is also charged that about twenty men called the authorized strike and violated an agreement providing for a notice of thirty days before a strike or lock-out would be effective.

The Gold Hill Miners' Union has posted notices at Gold Hill and Virginia City warning all union men to remain away from Gold Hill. The camp is branded as unfair, as are all men and contractors working on the Gold Hill properties, excepting the Comstock Home mine. This action follows the refusal of the Gold Hill companies to grant \$6 per day to miners. The old scale is \$5. It is reported that operators have practically decided to close their properties until next spring.

MEXICO

Sonora.—The Soyopa Silver Mining Co., a newly organized corporation of Nogales, Sonora, has purchased the famous old Hidalgo mine from R. G. Platt. Several thousand tons of high-grade milling-ore are blocked out already, and further active development will be undertaken at once. The Soyopa is an ancient high-grade silver district.

Active mining operations on the Catalina property, near Cananea, will be undertaken as soon as the new power-plant is completed. A new turbine and boilers are being installed. The shaft is being sunk an additional 1200 ft. A large part of the American employees of the Democrata mine, which recently closed down, are now with the Catalina.

Lack of a stable government in Mexico has had a disastrous effect on many mining companies operating in the more remote districts. The experience of the Batopilas Mining Co. is typical. In a circular to the stockholders the president says:

"In September 1913 our general manager and other American employees were called out of Mexico by the U. S. Department of State through the U. S. Consul at Chihuahua. In August 1914 an edict was issued from the office of the Governor of the State of Chihuahua to the effect that all mines not fully operated by their owners on September 1 would be declared open for denouncement. The general manager with several American employees returned to Batopilas and under great difficulties carried on some work until they were again notified by the Department of State to leave for the United States, having been in Batopilas about one year. During the absence of the American employees it was found necessary to allow the Mexican miners to work the mines on shares as the people were starving and threatened to enter and work the mines. These operations were supervised by our Mexican employees who, as best they might, safeguarded the company's interest. During the years 1916, 1917, 1918, and part of 1919 the company's one-third share of the product barely sufficed to cover the expense of supervision and guarding the properties of the company. In April 1919 the company commenced to take advantage of the increase in value of silver and shipped the silver bullion obtained from its one-third of the shareworkers' product to the United States and introduced Mexican gold to pay its employees. In December 1919 the general manager, John R. Harbottle, returned alone to Batopilas and has renewed and renovated the cyanide plant and has shipped out monthly small amounts of silver, the result of working up the low-grade ores and concentrates that had accumulated, as well as the company's one-third of the ores received from the shareworkers. . . . The attitude of the Carranza government was inimical to the development of foreign-owned properties. In the face of absolute lack of protection for our employees and properties, the taxes on our mining properties and the taxes on silver produced were enormously increased. This course was directly opposite to that of the former Mexican government which had encouraged the acquisition of large holdings of mining properties by a reduction in taxes on large areas. As a result of the various Carranza edicts, which are always accompanied by threats of forfeiture, the company has been compelled to relinquish some of its holdings that had been acquired under its contract, with the Mexican government, which specified that 100 mining claims (of about 2½ acres each) should be taken up each year. As the mining taxes were increased from three pesos per year on each claim to 18 pesos it became necessary to give up the unproductive claims, reserving only those properties that have produced silver in the past or that gave indications of being of value, including most of the original mines held, prior to the contract mentioned. Mining taxes and taxes on water power have been paid to date. Aside from the bond interest past due, the company has funds to more than cover all current liabilities."

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

D. M. Riordan is in New York.

W. J. Loring is at Lovelock, Nevada.

Charles Butters has gone to New York.

J. Power Hutchins is residing at Madrid, Spain.

W. W. Mein has returned to New York from California.

Eugene Dawson is on his way from New York to Iquito, in Peru.

A. W. Newberry has removed his office to 2 Rector street, New York.

John A. Rice has returned to San Francisco from Chihuahua, Mexico.

J. B. Stoddard, of the Stoddard Oil Co., New York, is at the Palace.

C. T. Hutchinson, business manager of the 'M. & S. P.' is in New York.

Francis M. Hartman, of Tucson, Arizona, is at the St. Francis hotel.

E. T. Keller, of Winnemucca, Nevada, was in San Francisco this week.

C. W. Purington has been examining coalfields on the island of Saghalin.

Olof Wenstrom has moved his offices from Boston to 60 Broadway, New York.

F. R. Weeks has returned to New York from the Salmon River district, in Idaho.

Charles Janin has returned from the Malay States and is now on his ranch near Santa Barbara.

Charles Smith, president of the Arizona Commercial Mining Co., visited the Globe district last week.

R. H. Page, general manager for the Truscon Steel Co., is here on his way from New York to the Orient.

J. Parke Channing is at Miami. He will attend the meeting of Engineering Council at Chicago on October 21.

Alfred H. Brooks, on his return from the North, stopped at Ketchikan to examine the copper deposits of that district.

John Kiddie, superintendent, and **J. G. Cooper**, auditor for the Arizona Copper Co., have been spending a few days at Tyrone, New Mexico.

H. Y. Eagle, mining engineer connected with the New York office of the Union Minière du Haut Katanga, has been visiting mining and metallurgical plants in Utah.

Ira B. Joralemon has been elected commander of the American Legion post at Bisbee; he is assistant general manager for the Calumet & Arizona Mining Co., at Bisbee.

Homer Guck, who was correspondent for the 'M. & S. P.' at Houghton, Michigan, for many years, is now associated with the Detroit Life Insurance Co. as assistant to the president.

R. E. Tremoureux, formerly manager of the Champion mines at Nevada City, has opened offices in the Hobart building, San Francisco, where he will specialize in machinery and supplies for mines.

Henry N. Thomson, at one time head chemist for the Anaconda company and later superintendent of the International smelter, at Tooele, Utah, has been appointed to the chair of metallurgy in the University of British Columbia, Vancouver.

W. H. Webster, assistant general manager of the Copper Queen branch of the Phelps Dodge Corporation, and **H. Kenyon Burch**, consulting construction engineer for the Phelps Dodge Corporation, have been visiting various mining districts in New Mexico.

Foreign quotations on October 5 are as follows:		
Sterling, dollars:	Cable	3.49%
	Demand	3.50%
Francs, cents:	Cable	6.76
	Demand	6.77
Lire, cents:	Demand	4.13
Marks, cents		1.69

Eastern Metal Market

New York, September 29.

Depression in most of the markets is pronounced and prices are lower. Low exchange values are a factor as well as imported metals.

Demand for copper is lighter than in many weeks and there is some weakness in values.

The tin market is exceedingly quiet with prices on the decline.

In lead there have been further price reductions with imported metal the large factor.

Buying of zinc is erratic and light and imports are an influence. Prices are lower.

There is no change in antimony.

IRON AND STEEL

The reductions in automobile and other prices in the past week have caused further shrinkage in iron and steel buying, and in a number of directions the market has shown weakness, says 'The Iron Age'. Accompanying the cut made by the Ford Motor Co. is a determined effort to force down the price of automobile steel. The Detroit company is expected shortly to buy steel on a large scale for 1921 and already some makers of automobile parts have been urged to make a downward revision of existing contracts. At the same time, the periods within which the mills can make deliveries on new orders have been shortened in a number of cases, pointing to a more rapid adjustment between supply and demand than seemed likely two months ago.

Among steel products, billets, plates, and sheets have furnished the chief tests on prices in the past week and all have yielded. The general tendency of pig-iron prices is decidedly toward lower levels.

COPPER

The unexpected has thus far developed in this market. The buying movement which was predicted and to which all signs pointed a few weeks ago has not developed and seems farther away than ever. Both inquiry and demand have fallen away and the apathy of buyers is hard to explain. There is perplexity among some leading representatives of the trade. While pessimism does not rule, the present situation is eminently unsatisfactory and the immediate future is hard to prophesy. There is almost no business. What there is is being satisfied by small producers and dealers at around 18.50c., New York, for both electrolytic and Lake copper. We quote the market at this level. Prices of most leading producers are nominal at 18.75c., New York, for October, with 19c. asked for forward positions, but they are booking but little for any positions. Low exchange-rates and disturbed political conditions abroad are unfavorable to export business, which is not as good as it was. Arrivals of copper from abroad are also a factor. They have totaled 6860 tons thus far this month. Importations of scrap copper of good quality from war material are also a factor in diminishing the demand for domestic virgin-metal.

The British copper market reached the highest level in four months on September 15 when it was £100 per ton, or about 17.50c. per pound. It has softened since, until yesterday it was £95 5s. per ton.

TIN

This market is extremely dull. Dealers are going slowly in their purchases and consumers are not active. There are no features. Sales of small lots under the hammer on the New York Metal Exchange continue, those for the week amounting to about 125 tons at prices ranging from 43.25 to 44.50c., depending on the position. On the 20th there was a sale of 25 tons under the rule at 44.50c. and on the 21st another sale of 25 tons of July-August shipment at 44.37½c.

The London market yesterday was lower than a week ago with spot standard quoted at £270 15s. per ton, future standard at £276 15s., and spot Straits at £273 15s., the week's decline being from £1 to £2. Arrivals thus far this month have been 3910 tons with 4385 tons reported afloat.

LEAD

Imported metal continues the dominant factor. Prices have again declined. The principal event of this nature was the reduction late last Thursday of ¼c. per pound in the quotations of the American Smelting & Refining Co. to 7.75c., St. Louis, or 8c., New York. This represents a readjustment to the level of the outside market. Arrivals from abroad continue with the feature consisting in lead from Germany, the first in many years. German lead for October shipment has been offered at 7.50c., New York, duty paid. Spot foreign lead is available at 7.75c., New York, which is quoted by the New York market. Domestic lead is quoted at 7.75c., St. Louis. There is much interest by buyers in either foreign or domestic metal, the buying apparently consisting of hand-to-mouth orders. Consumers are evidently not buying for stocks. It is estimated that close to 20,000 tons has been contracted for importation.

ZINC

Prime Western sold to England and re-shipped to this country is the principal influence in the Eastern market. It is available and sold at around 7.70c., seaboard, which establishes the New York market. Domestic prime Western is quoted at around 7.70c., St. Louis, for early delivery and there have been a few sales at 7.70 to 7.80c. Demand in general is light from any quarter. Consumers are buying only for immediate needs and producers are selling only what they have to. For forward positions they are not quoting if possible, nor are they forcing the nearby market.

ANTIMONY

The market is quiet and unchanged with wholesale lots for early delivery quoted at 7.12½c., New York, duty paid.

ALUMINUM

Quotations are unchanged, that of the leading producers being 34.90c. f.o.b. producer's plant for virgin metal, with the same grade from foreign sources available at 31 to 32c. per pound, New York.

ORES

Tungsten: Business has been quiet. There have been offerings without finding buyers. Spot Chinese ore is offered at \$4.75 per unit in regular concentrate and for higher-grade ore \$5 per unit is the asking price. The British price is 26s. per unit with ferro-tungsten quoted at 3s. 3d. per pound of contained tungsten. American ferro-tungsten is quoted at 80c. to \$1.05 per pound of contained tungsten.

Molybdenum: The market is still quiet and devoid of feature. Quotations are nominal at 65 to 75c. per pound of MoS₂ in regular concentrate.

Manganese: The market is very quiet with no interest shown by consumers, who seem well stocked. Sellers ask 60 to 65c. per unit, but buyers are willing to pay no more than 55c.

Manganese-Iron Alloys: The markets for both ferro-manganese and spiegeleisen are extremely quiet. No sales of the former are reported nor any demand. Quotations are unchanged for both British and domestic alloy on a basis of \$170, seaboard. Some re-sale British alloy has been offered at \$160, seaboard, but not sold so far as known. Except for the sale of 100 tons of spiegeleisen for Canada, demand is very light. Quotations are unchanged at \$82.50, furnace, for the higher grade and \$80 for the lower.

THE UNITED VERDE SMELTER			
By L. A. Parsons.....	547		
Work being done by present plant. Plans for doubling the capacity. Clarkdale the 'company town'. The Verde Tunnel & Smelter Railroad.			

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 31 Nassau St.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

Limited Floor Space?

Follow the Example of the Belmont Surf Inlet Mines, Ltd.

They are using six No. 9 Double-Deck Wilfleys with the excellent results so characteristic of Wilfley concentration wherever practised.

Increased table capacity is obtained per unit of floor space with no loss in efficiency. The lower deck is visible because of the wide space between the two decks.

If you have a concentrating problem—write our engineers. There is a type of Wilfley for every metallurgical requirement.

Adaptations can be made to suit the limitations of your plant and the character of your ore.

Over 22,000 Wilfleys are now in use.

No. 9 Double-Deck Wilfley Table

T. A. RICKARD, - - - Editor

IT is a pleasure to publish the article on the United Verde smelter by Mr. Lewis A. Parsons. This article represents a standard of technical writing that is rarely attained by the members of the engineering profession. Another pleasing feature is the mental hospitality of the management of the United Verde Copper Company, without whose courtesy and friendly co-operation the preparation of an article so rich in detail would have been impossible.

ON page 564 we publish a statement issued by Mr. Louis T. McFadden on the subject of the Bill presented by him before Congress for the purpose of levying an excise of \$10 per ounce on all gold used for manufacturing. It is surprising that the chairman of the Committee on Banking and Currency of the House of Representatives should have made such a blunder as to say that "since July 24, 1919, the British Empire has been paying an exchange premium as high as 50% to the gold producers of South Africa". Any banker in touch with foreign exchange could have told him that the premium on gold in London was the direct result of the removal of the embargo placed by the British government during the War on dealings in gold, that is, as soon as the war-time restrictions were removed the artificial value of sterling exchange dropped to its real level as measured in gold. That the gold producers of South Africa benefited from the premium was a minor consequence of the re-establishment of a free market for gold in London. Mr. McFadden has given currency to a misunderstanding that he ought to have been the first to correct.

STATISTICS of immigration are peculiarly interesting at this time, for they bear upon our economics all the way from the domestic kitchen to the largest industrial establishment. We have been cheered recently with statements from Federal officials that the tide of migration had turned strongly and that thousands were arriving daily at Ellis island, New York. Now come the figures of immigration for the first fiscal year ended on June 30. These show that 430,001 came to this country during the twelve months, while 288,315 emigrated, so that the net gain was only 141,686. Most of the newcomers hail from Mexico and Canada; the European influx was 246,295, and the efflux 256,433, so that we lost 10,000 to the trans-Atlantic countries. The total of 430,000 immigrants last year was only one-third that of

1914; moreover, of those who departed 80% were males, while of those who arrived 43% were females. Latterly there has been an improvement; during April, May, and June the male element increased 61% among the arrivals and decreased to 77% among the departures. It is estimated that an immigration of a million persons will be recorded in the current year, but we are sceptical as to that. Another important fact is that the supply of unskilled labor is being drained by emigration. During the year 183,280 laborers left our shores while only 81,734 came hither. Arrivals of skilled laborers and professional men increased in the ratio of three to one, but the supply of common labor, which is the foundation of industrial activity, decreased considerably. A shortage of at least three millions of ordinary workers was caused by the check to immigration during the War, and the exodus to Europe from this class of labor accentuated the loss. A new set of conditions has been established by the War and we shall feel their effects for many years, if not permanently.

MR. HOOVER's participation in the Presidential campaign, as a supporter of the Republican candidate, is in accord with his acceptance of Senator Harding's nomination. It has been rumored that Mr. Hoover will be in the next President's cabinet, for we assume that the Senator, not the Governor, from Ohio will be elected. Indeed, one of the arguments used by Mr. Harding's supporters is the expectation that he will select a strong Cabinet. Mr. Hoover has been mentioned as Secretary of the Treasury, with the idea that he will organize a budget system; likewise he has been slated for the Secretaryship of the Interior, for which he is qualified by his experience as an engineer. This would anticipate the bill before Congress whereby the Secretary of the Interior is to be an engineer and is to have in his department—to be changed to that of Public Works—all the engineering branches of the Federal administration. Mr. Hoover's services are valuable to the nation in whatever capacity he exercises them, but we doubt whether they can be exercised successfully under the conditions that will exist at Washington if and when Mr. Harding becomes President. He could, and would, work loyally with Mr. Harding, of course, but could or would he work harmoniously with the cabal by whom Mr. Harding will have been hoisted into office? Mr. Hoover is young; he will find other opportunities of devoting himself to public service; we hope that he will not jeopardize his remark-

able usefulness in this day and generation by becoming entangled in backstairs politics, which he does not understand simply because he despises it. He could serve the incoming President as disinterestedly and as efficiently as he served the outgoing President, but can he serve a senatorial junta?

A NEW method of flotation has been invented by M. B. Luckenbach, who started his investigations in San Francisco three years ago, but is now established at Brooklyn, New York. Accurate information is difficult to secure, but we learn that successful results have been obtained on various ores, notably in Utah. One interesting feature is the high recovery made in the treatment of oxidized ores, in which respect the new process is said to be superior to any heretofore known. The Canadian rights are reported to have been sold to Sir William Mackenzie, and a series of tests is now being made by the Ontario Bureau of Mines, at Ottawa. No special machine is required; both the Callow and Janney machines are quite suited to this new process, which makes a froth that functions well as a collector and is broken down more readily than the froth made by the use of oil. The only unfavorable feature of the story is the mystery in which the composition of the reagent is shrouded. We are told that it is not an oil, but everybody is not able to define what an 'oil' is, and in their enthusiasm to escape the clutches of Minerals Separation they are likely to give themselves the benefit of many scientific doubts. What is the difference between 'grease' and 'oil'?

THAT the U. S. Army gas-mask is not suitable for combating fires, in mines or elsewhere, is well known and warnings of this fact have been spread broadcast, but that the lesson has not been learned the fatalities at the Calaveras mine seem to prove. These lives will have been sacrificed in vain if attention is not directed to the fact, according to newspaper reports, that they were due to an attempt by men equipped only with masks of the Army type to enter workings filled with gases from a mine-fire. Mr. E. D. Bullard's letter, which we give on page 546, is to the point. He might have added two other sources of danger to the wearer of this type of mask. The Army mask is designed to absorb small amounts of poisonous gases and cannot furnish oxygen where it is lacking, as in combustion products. Gases from fires, as Mr. Bullard points out, contain large amounts of odorless carbon monoxide but they also contain small amounts of the pungent products of combustion, which serve as a danger-signal. The mask absorbs the latter but cannot absorb the large proportion of carbon monoxide; hence the wearer is deprived of the warning he otherwise would have had. The only value of the Army mask is as a protection against radiant heat.

GOVERNOR HARDING and Senator Harding are likely to be confused in the mind of the careless reader of a careless newspaper. The Governor of the Federal Reserve Bank occupies a position more important than that of the Senator from Ohio but less important

than the one to which the Senator legitimately aspires. Mr. William P. G. Harding, the financier, is a man of perspicuous utterance, and we read his statements with much respect. He has been explaining that we have passed through "a period of exhilaration or intoxication" and that "business generally is looking forward to a bountiful harvest and better prospects for the railroads". In this time of belated deflation the Federal Reserve banking system of this country is playing the part of an admirable regulator. It aims to promote and assist the gradual and orderly marketing of the crops, so as not to involve too great a strain upon our transportation facilities and our mechanism of credit. The high discount rate prevailing at the Federal Reserve banks is meant to check too large a volume of re-discounts and to prevent an excessive reduction in the reserve of gold, which is nearly at the legal minimum. The power placed in the hands of the Federal Reserve Bank to moderate the issue of loans and thereby to curb profiteering has been used in salutary fashion. The fulminations of the Attorney General have been ridiculously ineffective in disciplining those who have made the most of the critical conditions created by the aftermath of the War and it is fortunate that the Government has another branch of administration that has been able both to protect the public and to regulate the use of capital for industrial activities.

FROM London we have received a copy of the register of old students and history of the Royal School of Mines. Although the graduates from this college of mining are few in the United States, this volume is interesting to Americans for several reasons. The School, called 'Royal' because the Prince Consort, Queen Victoria's husband, was its sponsor, dates from 1851. It was the child of the Geological Survey of Great Britain soon after it was founded by De la Beche, who became president of the School. The list of the first faculty is notable, for it included Lyon Playfair, Edward Forbes, Robert Hunt, John Percy, Andrew Ramsay, and Warington Smyth. In 1855 Roderick Murchison succeeded De la Beche. In 1854 Huxley joined the staff; and shortly afterward, Tyndall. Huxley became dean of the faculty, and remained the guiding mind of the institution until he retired, in 1885. It must be conceded that the School is rendered illustrious by its professorate; Victorian science gave of its very best to the Royal School of Mines, but the School never received the support that it deserved from a country for which mining, at home and abroad, has done so much. It was driven from pillar to post and tied to various grandiose but inchoate schemes of technical education, so that its identity was swamped and its usefulness crippled. Despite these unfavorable conditions it has won a recognized position among British colleges and has produced several generations of men prominent in the mining exploration and development to which the British empire owes its expansion. When the War came, the School was true to its best traditions; the classrooms were denuded of their students. The Roll of Honor includes 72 young men who gave their lives for

the cause of civilization. In war and in peace the Royal School of Mines has made good.

IN this issue we publish the first of a series of three articles that have appeared in 'The Annalist' of New York on the subject of 'Labor, the Holder of the Nation's Wealth and Income'. The writer of them is Mr. Walter R. Ingalls, for many years and until last year the editor of the 'Engineering and Mining Journal', a technical periodical of high standing. Mr. Ingalls is a keen student and a careful observer; therefore we feel sure that his conclusions on such an important subject will be read with interest and respect. He sets out to prove that labor now and for many years has won the lion's share of the wealth produced in the United States. In view of the facts brought out by him it will be well to note the data prepared by the Monmouthshire and South Wales Coal Owners Association, showing that since 1914 the item of wages in the cost of producing a ton of coal in the United Kingdom has risen from 6s. 2.92d. to 22s. 8.75d., while, on the other hand, the production of coal has fallen from 230 tons per man per year to 190 tons. Whatever the coal miner's wages, his share of the total wealth produced in the country is measured by the amount he has contributed toward increasing the country's wealth; in this case he is not doing as much in 1920 by 17% as he did in 1914, and therefore he is only entitled, on this line of reasoning, to 83% as much of food, clothes, comforts, and luxuries. His increase in wages can only mean one of two things: either he is obtaining, at the expense of workers in other industries, more of the country's wealth than that to which he is entitled, or the general rise in prices has been greater than the increase in his wages, in which event his bigger wages will do him no good. Obviously if the same conditions obtain in other industries, and probably they do, then the only preventive of hard times is greater efficiency of production. In the United States likewise the workman generally is less efficient than he was before the War and he is spending more. This means a decrease in the *pro rata* stored wealth of our people, not the store of dollars and cents represented by paper currency, bank credits, or shares of stock, but the wealth in bushels of corn or wheat and pounds of cotton or steel. During the War the loss of wealth due to under-production was compensated by the sale of munitions and supplies to Europe, but now no such compensating factor is at work and sooner or later we shall have to pay the piper unless our rate of efficiency in production is increased.

The Japanese in California

The question of Asiatic immigration to this State has become a matter of lively controversy by reason of the fact that the people of California at the election in November will vote upon an initiative measure to make more stringent the laws restricting the privileges of the Japanese to hold agricultural land. The Japanese are not mentioned in the Bill, but "aliens ineligible to citizenship" means Asiatics, and the Chinese having been excluded for many years, the intent of the proposed legislation is obvious.

By an act of 1913 the legislature of California prohibited the owning of land by "aliens ineligible to citizenship", that is, Asiatics; and limited leases of agricultural land by them to a period of three years. Citizenship by naturalization is open, by Federal law, only to white persons and persons of African descent. The Chinese have been excluded from the United States by specific Federal act since 1882; the Japanese had been excluded from citizenship by judicial interpretation, until the Bureau of Immigration in 1911 ruled that a Japanese is not "a white person". It is claimed that the Act of 1913 has been evaded by the Japanese through the organization of corporations that acquire agricultural land, and by acquiring rights in the names of children born in California, and therefore both eligible to citizenship and entitled to own land. The measure that goes before the voters in California at the impending election prohibits the leasing or owning of agricultural land by aliens ineligible to citizenship; it prohibits such aliens from owning stock in corporations owning or leasing agricultural land; it prohibits such aliens from becoming guardians of that portion of the estate of minors which is agricultural land.

This is not the first time that California has shown her dislike of the Japanese. Until twenty years ago immigration from Japan was negligible; in 1899 only 2844 Japanese entered the United States; in 1900 the number increased to 12,635; in the year 1907 it reached 30,645. In that year, President Roosevelt, responding to urgent demands from California and other Pacific Coast States, and empowered by Congress to do so, issued an executive order denying entrance to Japanese laborers "who have received passports to go to Mexico, Canada, or Hawaii, and come therefrom". Concurrently the American and Japanese governments entered into the famous 'gentlemen's agreement' whereby the government of Japan agreed to cease giving passports to "laborers", except such as had been residents in the United States, or the parents, wife, or children of residents, and "settled agriculturalists". This agreement was observed effectively for a time; in 1909 only 3925 Japanese entered this country; after that a slight increase was recorded up to 1912, when 8589 entered; but since then the influx has gained in volume slowly until in the year 1919 it had risen again to 16,075. From all these figures for 'arrivals' it is necessary to deduct the 'departures'. Between 1902 and 1919 inclusive the grand total of 'arrivals' was 240,000, of whom fully half were transients, visitors to this country, and travelers to or from Europe. At the end of 1919 there were 87,279 Japanese in California, this being four-fifths of all of that race in this country. In a decade the total has doubled. These figures are issued by the State Board of Control and are subject to correction, but they are the only statistics available until the Census of 1920 is published. The people of our State have been told officially that the birth-rate among the Japanese is another menace; in ten years there was as much increase by birth as by immigration. Therefore they protested against the shiploads of 'picture brides', that is, the women selected by means of photographs and married by proxy to Japanese men in California. In consequence of

protests the Japanese government in February of this year made what may be called 'the ladies' agreement', whereby it promised to issue no more passports to 'picture brides'. The former Chinese immigration against which California protested so successfully was of men only, chiefly of coolies; the early Japanese immigration was likewise confined largely to male laborers; during recent years there has been a marked influx of women. It is complained that they and their children work in the fields with the men, thereby introducing another difference in the standard of living. By reason of their thrifty and industrious habits the Japanese are able to augment their holdings, establishing colonies, especially on irrigated lands, and competing successfully with American farmers. By subterfuge they evade the law that forbids them, unless born in the United States, to own land; they combine and co-operate; they are increasing in numbers and in property so fast as to attract the unfriendly attention of politicians looking for a popular cry. The coincidence of the Japanese crisis and the November election is significant. A good deal of the noise on the subject arises from the desire of politicians to curry favor with the classes that suffer by competition with the Japanese. However, there is real anxiety among thoughtful and fair-minded men lest the increase of the Japanese in California should prove injurious to this commonwealth, by introducing a large racial element incompatible with the American idea and prejudicial to our normal development as a white people. The question of inferiority or superiority of race does not arise; it is one simply of difference in traditions and ways of living. Politicians in Japan naturally express resentment against the proposal of the Californians to legislate against their emigrants. Twice a President of the United States has been compelled to send a member of his Cabinet to San Francisco to beseech the Californians to abate their impetuosity lest international trouble be caused. It seems to us that, as regards further Japanese immigration, the Japanese government should stop it, since it has been made clear that it is unwelcome. Of course, if the Japanese are to be debarred from California, they will have to be shut out elsewhere in this country, otherwise they will find their way hither. Presumably one nation can inform another that its nationals are not welcome. It is impolite, but it is better than ill-treating them when they arrive. All this refers, of course, only to the laboring class; it does not refer to Japanese merchants coming here to transact business or to Japanese students, scientists, and others of the educated class. They come as visitors, not as residents, and in any event it is not against them that popular prejudice has been aroused. Such an embargo on further Japanese immigration will be regrettable, from the standpoint of international courtesy, but it will be better than a recurrent squabble over the matter. As to the Japanese already here, their rights must be respected. To discriminate against them would be unjust and would give the Japanese government valid cause for serious complaint.

Whether some of the proposals in the initiative are contrary to the provisions of the Constitution of the

United States is another question, which will be decided in due course, if necessity arise. The decision of the U. S. Supreme Court in the case of *State of Missouri v. Holland*, handed down on April 19, 1920, has a bearing upon the question of the power of the States in the matter of excluding foreigners or regulating their right to ownership of land as against a possible negotiation of a treaty by the Federal government on the subject. Some years ago Congress passed an act for the protection of migratory birds. That act was held by two Federal courts to be unconstitutional on the ground that it was a usurpation by Congress of powers that had not been granted to it and that had been reserved to the States. Subsequently a treaty was negotiated between this country and Canada providing for such protection of migratory birds. Congress thereupon, in order to enforce the provisions of the treaty, passed an act protecting from destruction these migratory birds. The power of Congress to do this was challenged by the States and it was claimed that Congress should be held to be without power in the matter and the act declared void for the same reason that the former act was declared void. It was held by three local Federal courts, however, and has now been held by the Supreme Court, that even though an act of Congress might be void if it attempted to deal with subjects belonging to the States, nevertheless, if the subject in question were a proper one for negotiation of a treaty with a foreign power and the treaty did not infringe any express provisions of the Constitution, it would be valid, and a law of Congress passed for the enforcement of that treaty would be valid, although the power to legislate upon the subject would otherwise have been reserved to the State. This was so held because of the provision of the Constitution that "all treaties made or which shall be made under the authority of the United States shall be the supreme law of the land", and that the subject of the protection of migratory birds was a national interest as to which the United States was not forbidden by the Constitution to act. Although the right to regulate or prohibit ownership of land by aliens may rest ordinarily with the States, it may well be held that this subject is a proper one for international agreement by treaty, and that if regulated thereby the treaty would control and the legislation of the States would be superseded. So far as existing treaties are concerned, they are expressly recognized in the proposed initiative measure, which provides that aliens ineligible to citizenship "may acquire, possess, enjoy and convey real property, or any interest therein, in this State, in the manner and to the extent and for the purposes prescribed by any treaty now existing between the Government of the United States and the nation or country of which such alien is a citizen or subject, and not otherwise". It is evident that the possible incidence of a later treaty is not ignored. Diplomatic action is inevitable, and most desirable. The people of California are fully entitled to express their opinion in a matter that affects them most immediately and the Federal government will undoubtedly give heed to their wishes in so far as they do not conflict with the larger interests of the Nation.

DISCUSSION

Advertising Ethics

The Editor:

Sir—The letter, which you print in your issue of September 18, from the Pennsylvanian manufacturer who implies that he will discontinue advertising in your paper unless you make your editorials politically Republican, instead of independent as they now are, reminds me of the good old-fashioned method formerly used in the mining region of northern Michigan to elect mine officials to local political service. The mine captain usually ran for the principal office. In the school-house, or wherever the

they knew that business and capital are supporting the Republicans.

P. B. McDONALD.

New York, September 24.

Two Suggestions on a National Problem

The Editor:

Sir—Your friend J. H. Curle, the well-known British mine-valuer, once said that it is safer to be on the pessimistic side of a problem than otherwise. I am that way inclined concerning the fuel problem for automobiles

SUCTION GAS-PRODUCER SYSTEM

A. Producer. B. Evaporator. C. Scrubber. D. Receiver. E. Pipe for Water-Vapor from B. F. Fan for Starting Fire in A. G. Vent for Testing Gas.

voting was done, all the men who voted for the captain were lined up on one side of the room, and all who voted against him were lined up on the other. This enabled the captain to get a good look at those employees who opposed "normalcy". In case the opposition was numerous, the mine clerk could jot down the names. Either the captain was elected, or there was a big time at the mine the next day.

Evidently the Pennsylvanian manufacturer does not advertise in the 'New York Times', for I have not noticed that that prosperous paper has altered its editorials from their customary Democratic bias, although the advertising department is so deluged with business that several pages have to be refused each day because of lack of space. Likewise 'The World', which is fiercely Democratic, seems to attract all the advertising it can carry. The 'Evening Post', independent, apparently has not lost any ground by choosing to support Cox and Roosevelt. However, these papers undoubtedly would change sides if

and stationary engines; evidently Mr. F. H. Mason, judging by his letter in the 'Press' of September 11, is not. I am quite aware of the intense search the world over for new oilfields, some of the results from such, the increase in American petroleum production, the possibilities of oil-shales, and progress in by-product coke-oven operation; yet we must not forget the enormous increase in the consumption of crude oil and its distillates. I did not suggest "anything approaching panic", as Mr. Mason says; nor did I hint at the "innate stupidity on the part of the Briton", quoting him again (that remark was quite uncalled for on his part, what does he mean?), the words "an unsightly bag atop of the machine" being Captain Brewer's phrase, or to that effect. There is one point where Mr. Mason is entirely incorrect: I did not suggest using producer-gas as a fuel for raising steam, only in internal-combustion engines. Carbon monoxide, the gas so produced, is made in a producer from any class of coal, coke, charcoal, husks of

any kind, seeds, wood-waste, peat, sawdust, sugar-cane refuse, firewood, and such like, there being enormous quantities of waste in this country that could be so utilized.

There are two gas-producer systems, the pressure and suction. The former is more suitable for large power-units, and occupies more space than the suction system. In the pressure type, air required for generation of carbon-monoxide gas is used in the producer under pressure from an auxiliary source; but in the suction type, air is drawn through the producer by the piston of the gas-engine. Attention here will be paid to suction-gas power, and the accompanying sketch is almost self-descriptive.

Any of the fuels mentioned are fed into *A*, which has a feeder somewhat on the principle of the top of a blast-furnace. The fuel is lighted, and the fire urged for a few minutes by the fan *F*. The hot gas from *A* passes through *B*, which is practically a small water-tube boiler, producing steam for mixing with the air for making the gas in the producer. The first gas made is of poor quality, so until it is rich enough it is allowed to escape through the vent *G*. As the final gas from *A* is hot and dirty, it must be cooled and cleaned, so it passes through *C*. This is a steel cylinder filled with coke, over which water is sprayed, and as the gas passes through it, the heat and rust are abstracted. *D* is a receiver, gas-holder, or regulating tank between the scrubber and engine. If the fuel contains any tarry matters, an extractor consisting of a series of baffle-plates in a tank is placed in the circuit. When the engine is working, the piston sucks air and steam through the fuel, then the gas as made to the cylinder. After all is in order, the whole operation is automatic, save feeding fuel at regular intervals.

Mr. Mason appears to try to condemn producer-gas plants, and from his deductions engineers unacquainted with their operation would not be impressed with them; also, according to him, British and European practice has been inefficient for many years. (Crossley's in England has led in producer-gas plants for 40 years.) The thermal efficiency of suction-gas plants averages over 20%, up to 30%; while that of steam-plants is less than half of the higher figure. As for cost of operation, the gas plant leaves the steam-plant far behind. Mr. Mason must not forget that the very latest development in propulsion of motor vehicles, and adopted by the British government for Army trucks, is the Smith device that makes and uses producer-gas on the car itself.

M. W. VON BERNEWITZ.

Sierra City, California, September 25.

Salting of Mines

The Editor:

Sir—Being a constant reader of your paper, I have from time to time noticed the articles under the title above given, and in the discussion column. I wish to mention three methods to which, as I remember, I failed to see any of your contributors refer. As all mining engineers will agree, both hand and machine powder is folded over carefully on each end. It follows that in the bulk-sam-

pling or in making mill-test runs of ore in large mines it is possible for the ends of each stick of powder to be raised and a lot of the good old salt of the earth to be injected therein. Another way for hand-samples to be enriched is that in small mines or properties where limited development obtains, it is possible for the quartz or ore to be enriched in the following manner: The drilling of minute holes all over the exposed faces where an examining engineer would be likely to take samples, some chloride or virgin gold to be put into the holes prior to examination. I was told of a happening in Baker county, Oregon. Two engineers were to report at the same time. The first payment of \$5000 depended on the assay-returns secured from the bottom of a forty-foot shaft. The engineers insisted that the drillings be saved from a complete round of holes. They stood and watched the miner all the time, and the method used was that the miner had a small bottle of virgin gold up one sleeve and would allow the gold to run down into the drillings.

Fields, Oregon, September 28. FRED. H. LORENZ.

Gas-Masks

The Editor:

Sir—In the face of the Calaveras Copper disaster, where two men lost their lives, because of the lack of knowledge that the U. S. Army gas-mask is worse than useless in fighting mine-fires, I think that your paper could do a good deal of educational work along this line.

Since the Armistice, the U. S. Bureau of Mines, the California Industrial Accident Commission, and the California Metal Producers Association have tried to bring to the attention of all mining men that in case of fire the only means of entering the same should be with an approved self-contained breathing apparatus and that gas-masks of the Army type should on no account be used.

Among the majority of ex-service men, who found the gas-mask a wonderful protection against the German gases, there arose a belief that the mask was the 'be all and end all' in the way of gas protection. But this tragedy at the Calaveras mine, sad though it is, should at least have the good effect of showing, once and for all, that this is not true and a mask should never be used. The U. S. Army mask was made for protection against war gases of which carbon monoxide could never be one, as it is lighter than air and would not stay on the ground. In the case of other gases, their density was quickly dissipated by the open conditions in which the gases were loosened and the percentage of gas was very small. In a mine-fire, carbon monoxide is the deadliest of all gases, and goes through the Army mask immediately, giving the wearer no protection. If other gases are present, they are so highly concentrated because of the confined condition of the mine that they would also go through the mask and poison the wearer. Therefore the only solution to the problem of fighting fires is to wear a self-contained breathing apparatus of the approved type and this cannot be too strongly borne in upon the mining world.

San Francisco, October 5.

THE UNITED VERDE SMELTER AT CLARKDALE, ARIZONA

The United Verde Smelter

By L. A. PARSONS

INTRODUCTION. The smelter of the United Verde Copper Co., at Clarkdale, Arizona, at the time of my visit in February was producing nearly 7,000,000 lb. of copper per month from 74,000 tons of ore, this, of course, being much below its capacity. Although working under restrictions as to output, and suffering, as are all industries nowadays, from excessive and rapidly shifting costs, the results that are being obtained compare favorably with the best that is being done in modern copper smelting. In particular, the blast-furnaces, in smelting 8.5 tons of charge per square foot of hearth-area, and in producing, from a 5.87% ore, a 25.7% matte with a coke consumption of 5.85%, are worthy of much more study than the time at my disposal permitted me to make. Costs¹ for January, a representative month, were, without credits,

\$1.84 per ton of charge for blast-furnace operation; \$2.13 for reverberatories; \$0.23 for Wedge furnaces; and \$12 per ton of blister copper for converters. The total recovery for the same month was 88.54%. Considerable of this loss is in the stack-dust, and will be saved by a large Cottrell treater now designed and authorized.

During this period of reduced production the management is proceeding with the enlargement of the smelter. The present plans call for a plant capable of producing 12,000,000 to 15,000,000 lb. of copper per month when the market warrants, the ore for this to come from steam-shovel work in the fire-zones of the mine. The increased smelter capacity is to be obtained by doubling the number of roasting and reverberatory furnaces, the blast-furnaces remaining the same. This will also double the power to be obtained from waste-heat, giving a total of 8400 boiler horse-power from this source. The increased ore-tonnage will require a new crushing-plant, which will be erected at the smelter. This will supersede the present one at the portal of the Hopewell tunnel. It will be of the type used at the steel mills, that is, stock-piles and gantry-cranes, and will have a storage capacity of 250,000 tons. Another innovation is coal-dust firing of the reverberatories to supersede the present system of oil-firing. The new plant for preparing the coal-dust is nearly completed, and has many interesting features of design. Mr. Tally informs me that one lack which for a

¹I cannot avoid commenting upon the extraordinarily liberal policy of the management with regard to giving out costs, charges, and other information that most companies guard jealously, and I must express my appreciation of the exceptional facilities extended to me. It is not practicable here to thank in person all those who courteously assisted me in my study of the plant and its operation, but I wish especially to acknowledge my indebtedness to R. E. Tally, the assistant general manager for the United Verde Copper Co.; to Tom Taylor, the smelter superintendent; to C. R. Kuzell, the assistant smelter superintendent; to C. M. Hoffman, the superintendent of machinery; and for many valuable statistics on ore production to H. DeWitt Smith, the superintendent of mines.

long time has been felt at the smelter is a suitably equipped research department, and plans are now under way to remedy this. One of the first problems of the new department will be the recovery of the zinc in the flue-dust.

Clarkdale, the site of the smelter, is a 'company' town that shows, in its well-ordered streets, attractive dwellings, and a modern hospital, a concern for the welfare and contentment of the employees that is worthy of the best traditions of the mining industry. It is situated in the Verde valley at an elevation of 3560 ft., four miles north and 1700 ft. below Jerome, the principal business centre of the mining district and the operating headquarters of the United Verde mine. Communication with the outside world is maintained by the Verde Valley branch of

THE RAILROADS OF JEROME

the Santa Fe railroad, which connects with the Ash Fork-Phoenix line at Cedar Glade. The ore is brought over the Verde Tunnel & Smelter railroad, which connects Jerome with Clarkdale. Limestone for flux is shipped over the same road from a quarry close to the right-of-way.

This railroad, which is new, is a subsidiary of the United Verde Copper Co. The ore is loaded at Hope-well, a crushing-plant and loading-station at the portal of the main adit, which taps the United Verde mine at the 1000-ft. level. From the station at Jerome to Clarkdale is 10.7 miles by railroad, a drop of 1700 ft.; from Hopewell to Clarkdale is 6.7 miles and a drop of 940 ft.² The road is of standard gauge and will eventually become the main line to Jerome, superseding the present narrow-gauge and tortuous tracks connecting Jerome with Jerome Junction. Although a great improvement over

²Jerome is built on the side of a mountain, and different parts of the town differ greatly in elevation. The surface of the mine is several hundred feet higher.

the older road, the almost precipitous drop of the mountains to the Verde valley rendered its construction no simple problem, and it is essentially a mountain railroad. The grade is compensated 4% for its entire length; the longest tangent is 800 ft., and the maximum curvature 24°. Ninety-pound rails were used. At the time of my visit the ore-trains were being hauled by locomotives with cylinders 21 by 26 in., 164,000 lb. on drivers; but as these could haul only 200 tons up the 4% grade, they were being replaced by Mallet locomotives, which are expected to haul 600 tons or 27 empties. These locomotives have 376,000 lb. on the drivers. The ore-cars are steel 60-ton bottom-dump of 1228-cu. ft. capacity, built by the Pressed Steel Car Company.

CLASSES OF ORE. The ore as mined is divided into four classes according to its chemical characteristics, which dictate different methods of treatment or use at the smelter. The mining of the ore has recently been covered exhaustively by an able and comprehensive paper to be presented at the Lake Superior meeting of the American Institute of Mining Engineers in August,³ to which the reader is referred for further details; here only sufficient will be given to enable the metallurgist to understand the problem that must be solved by the smelting department. The names applied to these classes of ore—'oxide', 'iron', 'silica', and 'converter'—have been in local use for many years, and some of them are now misnomers, as will be seen from the descriptions and analyses. The bulk of the tonnage consists of the iron and silica ores.

Oxide Ore. This is a small tonnage, less than 3% of the total, mined from the oxidized zone above the 160-ft. level. A small amount of primary sulphides is present, but in general the copper content is low.

Iron Ore. This comes from stopes within the massive sulphide areas of the mine, and contains the highest copper content of the four classes. Ore from these stopes containing 15% or more of silica is classed as 'silica ore' and is diverted to the silica ore-bins.

Silica Ore. The ore from all black-schist stopes and from porphyry stopes assaying less than 50% total silica is classed as silica ore, together with the ore from the sulphide stopes containing more than 15% silica. It will be noted that this name is particularly misleading, as the iron is often in excess of the free silica and most of the silica is combined with alumina.

Converter Ore. This is a high-silica low-copper ore mined in the quartz-porphry, and is used for flux in converters and for fettling reverberatories. A small ton-

THE OLD SMELTER AT THE MINE

THE NEW SMELTER AT CLARKDALE

nage is mined from stopes near the contacts with the sedimentary schist, but the main supply comes from a large secondary-enrichment orebody situated some distance from the main orebodies.

In addition to these four classes, a small amount of precipitate is recovered from the mine-water. The table on page 548 gives detailed assays and tonnages for each class produced during 1918.

It has been calculated by the staff that these assays correspond to the following mineralogical composition:

Mineralogical Composition of Ore Shipped to Smelter

	Proportion contained in various ores			
	Oxide	Iron	Silica	Converter
Pyrite	5	59	28	5.75
Chalcocyprite	18	18	1.00
Sphalerite	4	2	0.50
Chalcocite	2	1.50
Cuprite and carbonates, native copper	0.25
Cuprite	1
Sulphates and carbonates of iron, copper, and lime	3
Iron oxides	46	2	2	11.00
Ferruginous chloite	38	6.00
Quartz	28	5	5	54.00
Silicates (sericite, hornblende, kaolin, etc.)	15	10	9	20.00
Calcite and siderite	2
Total	100	100	100	100.00

DISTRIBUTION OF THE ORE. The oxide ore is usually wet and sticky, and goes direct to the blast-furnaces without preliminary crushing. The converter, silica, and iron ore all go through the crushing-plant at Hopewell. This is an old plant and at present is considered by the staff to be more or less of a makeshift, pending the construction at the smelter of a new plant embodying modern principles of design. At Hopewell all ore except the oxide is crushed to 4 or 5 inches by a No. 9 gyratory and screened over 1½-in. square holes. The oversize of the silica and iron ore is the main blast-furnace feed. The oversize of the converter ore is re-crushed at the smelter and is used for flux in the converters and reverberatories. The size to which this is crushed varies from time to time owing to the present inadequate crushing facilities. The size that has been found by the smelter staff to be most suitable is about that of ordinary marbles with the dust removed, but this cannot always be obtained with the present equipment. When the new plant is in operation all the converter ore will be crushed to this size.

The converter, silica, and iron ore, after going through the 1½-in. square holes, is re-crushed at Hopewell by two 48-in. vertical Symons disc-crushers, one of which is kept as a spare, and by four 54 by 24-in. rolls to pass a ⅞-in. round hole, and thence goes to the roasting-furnaces. This size also leaves much to be desired, but it is the best that the present plant will do. The pyrite in the ore is an extremely hard massive variety, and its physical properties are such that, when as coarse as half an inch, it will not roast well in the ordinary time of travel through a roasting-furnace.

There are two bins for ore at the smelter, each with a capacity of 14,000 tons, giving a total storage of 28,000 tons. The bins over which the entering tracks pass are used principally for coarse, only two compartments being reserved for fine. The other bins are used for the storage

of fine, which is transferred by belt-conveyor and elevator from the two receiving compartments. The chutes under the coarse bins discharge into weighing-hoppers, each of which will hold approximately three tons of iron ore. The charge, weighed and ready when the charge-train runs under the bins, is thus quickly tripped into the cars. The fine, however, is measured by a different method; instead of discharging into weighing-hoppers, it is run through calibrated gates onto 30-in. belt-conveyors. These gates are opened to a width giving a fixed number of tons per hour, so that mixtures containing the desired proportions of different types of ore are made directly on the belt. The charge is elevated to the roaster-bins by a 20-in. belt-conveyor at an angle of 15°. All the charge goes to the roasters on the day-shift, and in order to continue this practice, when the heavy tonnages from steam-shovel operations⁴ start to come in, the 20-in. belt will be replaced by one 30 in. wide. As soon as the roaster-charge has been made up, an underground conveyor diverts the fine to the elevator leading to the fine-storage bin.

ROASTER PLANT. The present roaster plant consists of twelve 21½-ft. 6-hearth Wedge furnaces with an additional drying-floor, driven by a 35-hp. motor. Twelve additional roasters are being erected to handle the steam-shovel tonnage, each 22½ ft., with 7 hearths, an extra hearth being substituted in place of the drying floor because the compact structure of the sulphides requires more time in the furnace than the present type permits. An unusual feature of all these furnaces is that they revolve on roller-bearings running in oil. Even with the restricted production at the time of my visit the present roaster plant was badly crowded, the figures for January showing an average of 93.2 tons per furnace-day, against a rated capacity of 75 tons. Forcing the roasters to such an extent required the use of 1725 bbl. of fuel-oil, an average of 4.7 bbl. per furnace-day. This expense will be obviated when the additional roasters are in operation.

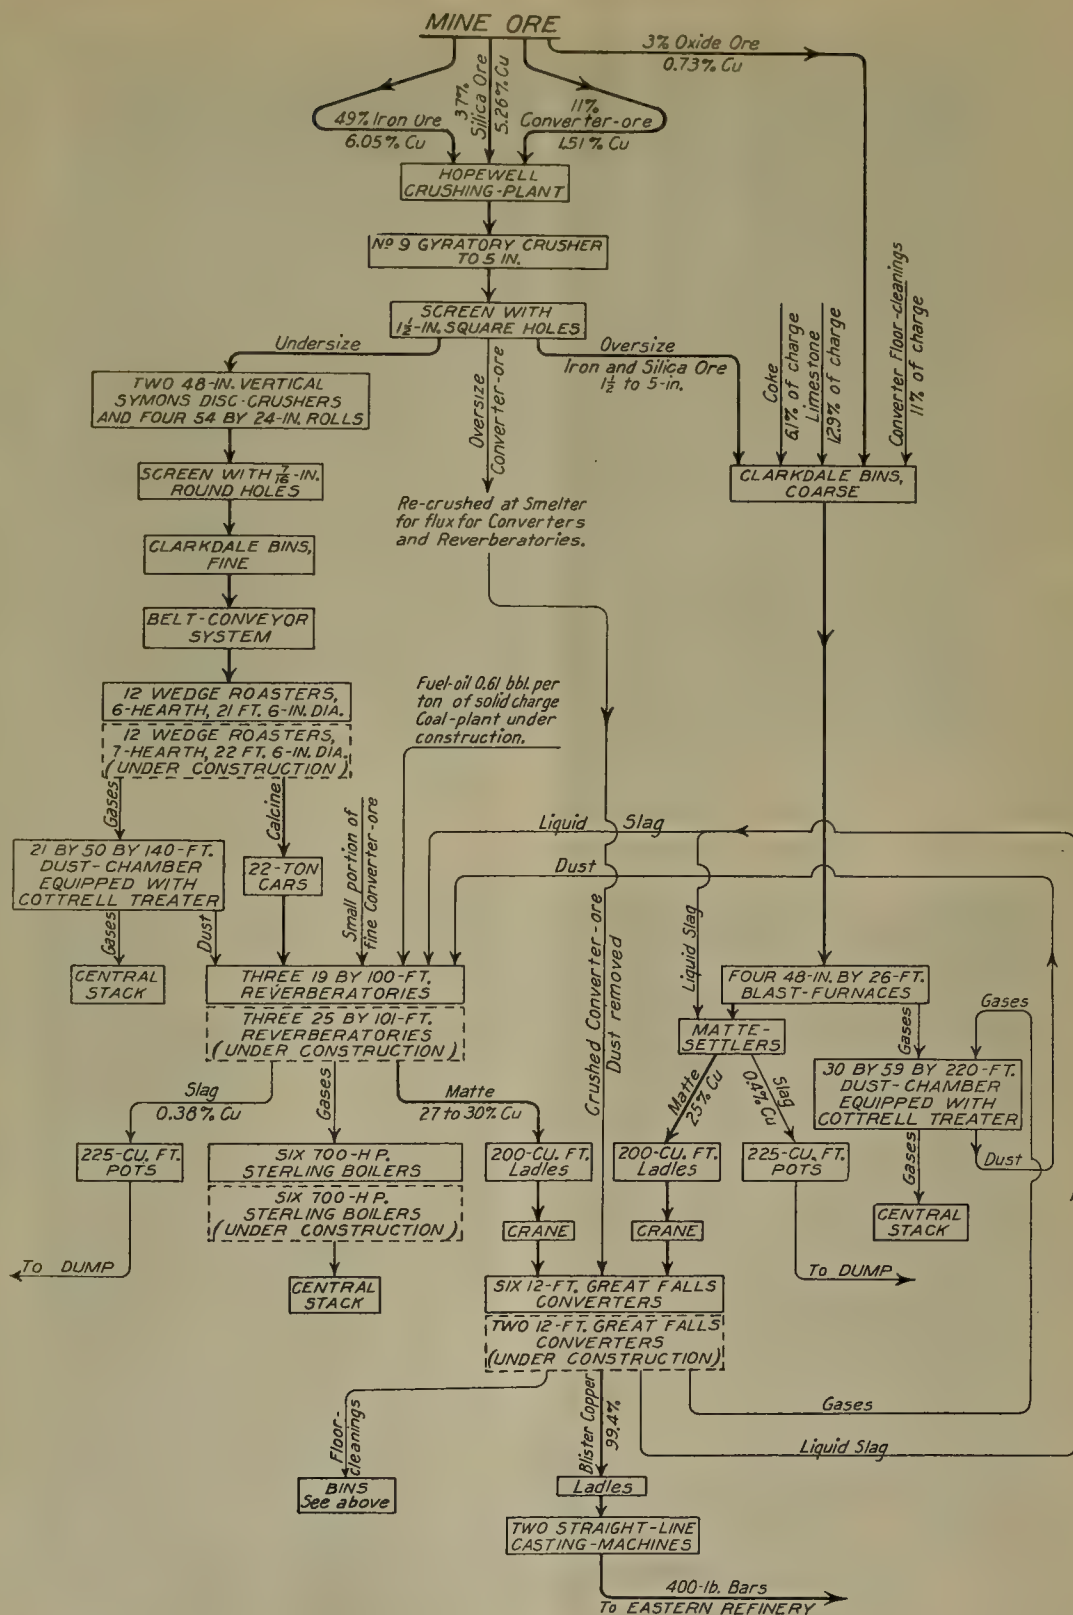

The fume from the roasters discharges through a dust-chamber 50 ft. wide, 21 ft. high above the top of the hoppers, and 140 ft. long, into the central stack, which is 30 by 400 ft., made of self-supporting steel and lined with Gallup brick. A 20-ft. section in the middle of the dust-chamber has wires hung at three-inch centres, but these are being superseded by an agglomerator type of the Cottrell process, known as the Frisbie modification.

The calcine is hauled to the reverberatories in cars holding 22 tons, by 10-ton electric locomotives, driven by 250-volt D.C. motor.

The statistics on roaster operation for January are as follows:

	Tons charged	Copper, %
Converter ore	4,400	1.51
Silica ore	13,963	5.26
Iron ore	15,906	6.05
Total	34,269	5.15
Calcine recovered		28,649
Shrinkage, tons		5,620
Shrinkage, per cent		16.40
Furnace-days		367.56
Tons charge per furnace-day		93.2

⁴These steam-shovel operations at the mine will be described in a succeeding article.

FLOW-SHEET OF THE UNITED VERDE SMELTER

Costs for the same period are as follows:⁵

	Per ton of charge	Per ton charged
Belt-conveyors	\$0.03	
Fuel-oil (crowding roasters)	0.12	
Operating	0.07	
Unclassified	0.01	
Total calcining per ton of charge.....	\$0.23	
Slag removal		0.07
Unclassified		0.04
Waste-heat credit		\$2.13
		0.54
Cost without calcining		1.59
Calcining per ton reverberatory charge.....		0.25
		1.84
Credit smelting blast-furnace flue-dust.....		0.08
Net cost reverberatory smelting.....		1.76

THE REVERBERATORY PLANT in present use consists of three 19½ by 100-ft. oil-fired furnaces, with a rated capacity of 650 tons of solid charge plus 120 tons of converter slag per day. Like the roaster plant, this department is being enlarged by the construction of three more furnaces, each 25 by 100 ft. The furnaces now in use are ample to take care of all the calcine that can be put through the present roasters. The lining is ordinary silica brick, except around the tap-holes, where chrome brick is used. The roofs are ribbed similarly to those at Anaconda. The length of campaign with the 19½-ft. furnaces is about 100,000 tons without patching the roof; it is expected that the new furnaces will handle 150,000 tons.

The gases from each furnace pass through two B. & W. Sterling 700-hp. boilers, making six in present use and six more to be constructed with the new furnaces. In addition, two similar furnaces are direct-fired by oil-burners. The steam is carried to the power-house in a double 10-in. header.

The matte is tapped near the uptake or flue end of the furnace and in order to avoid the use of long launders to convey the matte to the converter-aisle a tunnel has been constructed between each pair of furnaces and at right angles to the aisle. The matte is tapped into a ladle, which is carried on a small truck in the tunnel. After delivery to the converter-aisle on this small truck the 200-cu. ft. matte-ladle is carried by crane to the converters. The slag from all the furnaces is hauled to the dump in 225-cu. ft. electric-tilted slag-pots by an 18-ton electric locomotive.

The statistics on reverberatory operation for January are as follows:

	Tons	Copper. %
Converter ore (fettling)	504	1.51
Calcine	28,649	6.40
Blast-furnace flue-dust	1,338	14.80
Roaster-dust	1,577	6.30
Total	32,068	6.67
Furnace-days		62
Tons per furnace-day		517

In addition to the ore-tonnage, approximately 120 tons of liquid converter-slag is charged per day.

	Bbl.	Bbl. per ton of solid charge
Fuel-oil	19,484	0.61
Credit waste heat	6,819	0.21
Balance charged to reverberatories	12,665	0.40

The matte ranges from 27 to 30% copper and the slag averages 0.38% copper and 36% silica.

Costs for the same period are as follows:

	Per ton charged
Tramming and weighing	\$0.09
Fuel-oil	1.54
Operating	0.39

⁵All costs given in this article, both for this and other departments, are for operating and repairs; they include no overhead nor supervision above the grade of shift-boss.

Fuel-oil costs \$2.53 per barrel f.o.b. smelter. All reverberatory furnaces are being equipped for pulverized coal. The coal plant is described later in this paper.

BLAST-FURNACE PLANT. There are four blast-furnaces, each 48 in. by 26 ft., with 48 tuyeres of 4½ in. diameter. A feature of these furnaces that is rather a novelty is the Giroux hot-blast top, by means of which the blast is heated to 100° or 150° above the atmospheric temperature. No research has been done to determine the exact effect of this; it has been in use a long time, and is considered by the smelter staff to be beneficial. The blast-pressure varies from 22 to 40 oz., depending on the capacity desired. No pulverized coal has yet been blown through the tuyeres, but the management expects to undertake experiments with this process. The fume discharges into a dust-chamber 220 ft. long, 59 ft. 2 in. wide, and 29 ft. 6 in. high above the hoppers, but when the Cottrell plant is completed the fume will pass into it. The matte is tapped directly into 200-cu. ft. ladles in the converter-aisle, and the slag is hauled in 225-cu. ft. slag-pots. Liquid converter-slag was formerly dumped into the settlers, but with the exception of an occasional ladle it now all goes to the reverberatory furnaces.

The statistics on operation for January are as follows:

	Tons	Copper. %
Silica ore	12,932	5.26
Iron ore	18,530	6.05
Converter ore	41	1.51
Oxide ore	2,472	0.73
Swansea lease	562	22.86
Total ore	34,537	5.64
Limestone	5,862	...
Smelter cleanings	4,988	...
Total charge without coke.....	45,387	5.39
Furnace-days		61.8
Tons per furnace-day		734
Tons per square foot of hearth-area.....		7.06
Coke		6.1%

The matte averages 25% in copper and the slag 0.4%.

Costs for the same period are as follows:

	Per ton charged
Tramming and weighing charge.....	\$0.09
Coke	0.93
Air	0.24
Operation	0.30
Flux	0.10
Slag removal	0.07
Unclassified	0.05
	\$1.78
Reverberatory charge for flue-dust.....	0.06
Total per ton of charge.....	\$1.84

Coke cost \$15.32 f.o.b. smelter during this period. The smelter staff is engaged in increasing the efficiency of the blast-furnaces. Considerable improvement has been made in comparison with former practice, but it has not yet been determined just what results can be

VACUUM HEADER IN COAL-PULVERIZING PLANT

GATES AND CONVEYOR UNDER COAL-STORAGE BUNKERS

obtained. The best result so far obtained was in March, the record for which is as follows:

Tons per furnace-day.....	908.4
Tons per day per square foot of hearth-area.....	8.5
Coke per ton of charge.....	5.85%
Coke per ton of cupreous material.....	6.48%
Copper in charge.....	5.87%
Copper in matte.....	25.7%

Although this record is gratifying, the smelter officials have hopes of doing even better, particularly in cutting down the proportion of fuel. Some runs have been made with 4.5% coke, but so far not for a continuous month.

A study of the figures of cost will throw an interesting side-light on the controversy over the relative merits of the blast-furnace and the reverberatory. Giving credit for waste-heat, the cost of reverberatory treatment, including calcining, for the month under consideration is \$1.84 per ton of charge, exactly equal to that of the blast-furnaces, which must pay for having their flue-dust smelted. The blast-furnaces, however, were being operated at capacity and the reverberatories were not, which throws this comparison somewhat in favor of the reverberatories, although the cost of the finer crushing necessary before calcining is not included. As these costs are so nearly the same, the attitude of the management is significant. At present some ore of blast-furnace size is being crushed in order to smelt it in the reverberatories, and with the completion of the new reverberatories this will be still more the practice. It is planned at that time to make any necessary curtailment of output, as market conditions fluctuate, by shutting down blast-furnaces and smelting a larger proportion in the reverberatories.

Without the waste-heat credit, the reverberatory and calcining cost is \$2.38, a result that, at this plant, would have thrown the argument strongly in favor of the blast-furnace. Thus the waste-heat here, as in most of these comparisons, is seen to be the critical factor. Water-power in Arizona is scarce; hydro-electric plants are few; a large part of the electric power used over the State must be generated by steam, and this is expensive. The United Verde pays from 1 to 1½c. per kw-hour to the Arizona Power Co. for the excess power it may require. This high rate for power makes waste-heat exceedingly valuable; practically the entire power-plant is run by it, and a waste-heat credit of 54c. per ton of charge is the result, an advantage that no blast-furnace could hope to overcome on other than the most refractory ore. Although somewhat of a digression, it may here be noted that at the time of my visit to the United Verde Extension smelter, which will be described in another article, only the reverberatory was being operated, the same condition of expensive power causing the management to meet a necessary reduction of output by shutting-down the blast-furnace.

This condition of expensive power, however, does not exist where hydro-electric energy is available. Companies owning their own hydro-electric plants and delivering ample power cheaply, find that the waste-heat credit from their reverberatories dwindles to a few cents; the comparison is made almost purely on operating characteristics, and at many places a preference for the blast-

furnace is the result. The Sudbury district is an example of this kind, the greater part of the smelting there being done in blast-furnaces, although even there the comparison is a close one, and much of the preference for the blast-furnace is undoubtedly due to the momentum of existing practice. Where waste-heat cannot be used economically for power, its re-use in the reverberatory is the only alternative. All methods so far developed for doing this rely on some form of the regenerative checker system, and metallurgists seem to have a strong aversion for the cumbersome plant required and the operating difficulties introduced by the necessary reversal of gases.

CONVERTER PLANT.—There are six 12-ft. basic converters of the Great Falls type, of which five were in operation. Two more stands are under construction. The lining is magnesite brick 15 in. thick. Each converter has 16 tuyeres of 1½ in. diameter. These are double, containing an inner pipe that can easily be replaced. The air-pressure averages 14 lb. The converters are tilted by Allis-Chalmers 50-hp. motors, 440 volt, 65 amp., 60 cycle, acting through a steel worm turning a 70-in. brass gear. As the brass wears it is removed from the spider and a new one substituted. Since power is on tap from two sources, the United Verde power-plant and the Arizona Power Co., and the converter air is furnished by steam-operated units, there is no danger of freezing the tuyeres.

As previously noted, the matte is transferred to the converters, from both reverberatories and blast-furnaces, by 200-cu. ft. ladles. Flux is fed by gravity through spouts leading from overhead bins, which in turn are kept supplied by a belt-conveyor. The matte is blown to 99.4% blister, which is carried by ladles to two straight-line casting-machines, and cast into 400-lb. bars, which are shipped East to be refined. As much slag as the reverberatories can handle is treated by them, the excess going to the blast-furnace settlers; and this has been reduced to only an occasional ladle.

The cost of converting in January was \$12 per ton of blister copper.

PULVERIZED-COAL PLANT. In taking up the mechanical equipment, those vital accessories on the smooth working of which the very life of a smelter depends, perhaps the most interesting department is the new plant, not yet completed, for treating the coal to be used in firing the reverberatories. This plant is particularly interesting, not so much because this method of firing reverberatories is comparatively new, but because it represents a most recent decision of the management as to the apparatus and arrangement best fitted to meet its needs. When this plant is completed, coal-dust will displace the oil now used for firing the reverberatories.

The coal as it comes into the smelter-yard will be stored under water in two concrete open-top bins holding together 15,000 tons. An Alliance Machine Co. gantry-crane with a 2½-yd. clam-shell bucket serves these bins, filling them from the railroad cars, and transferring coal as needed into smaller bins feeding a belt-conveyor system. The first belt-conveyor is 36 in. wide; at the end of

the bins it rises at an angle of 15° , dropping the coal into the primary breaker, which is driven by a 50-hp. motor. From the primary breaker the coal drops onto another belt-conveyor, which carries it to the dryer-building. This is equipped with two Ruggles-Coles A14 coal-dryers, each driven by a 200-hp. motor. Space is provided for the erection of a third dryer, if it is found to be necessary. From the dryer-building the coal passes to two Jeffries coal-disintegrators, thence by bucket-elevator to the bins in the pulverizing-building. Space is provided for a third disintegrator. From the bins in the pulverizer department the fine coal drops into eight 5-roller Raymond impact-pulverizing mills. The blowers main-

can be flushed easily with water and the accumulation of coal-dust reduced to a minimum.

Since the writing of this article the coal-plant has started operations and has been found to be remarkably free from dust.

THE POWER-PLANT. The factors influencing the design of the power-plant were expensive power, the need for auxiliary units for generating electric current when the lines of the Arizona Power Co. failed, and a large supply of steam from the waste-heat of the reverberatories. With three reverberatories in operation this amounts to 4200 boiler horse-power; with the completion of the new reverberatory plant this will be doubled. Most of the blowers and compressors are driven by steam, but some

TOM TAYLOR, SMELTER SUPERINTENDENT, UNITED VERDE COMPANY

tain a 16-oz. air-suction at the top of each mill, and the coal stays in the mill until it is fine enough to be lifted by this current of air. From the mills the suction carries the coal-dust to a 16-in. screw-conveyor, by which it is conveyed to a 60-ton bin in front of each reverberatory. Firing will be done through five burners for each furnace.

In the general arrangement of the entire coal-plant, and its relation to the reverberatories, every precaution has been taken against fire and explosions. The dryer and pulverizer buildings are built of brick and concrete on a steel frame, and are conspicuous for the ample space provided, the large windows, and the amount of ventilation. There is no crowded machinery and there are no awkward angles to catch coal-dust. The conveyors and other necessary apparatus are so arranged that the floors

COAL-DUST COLLECTORS IN DRYER PLANT

are electrically driven, as will be noted in the list of equipment, and one stand-by blast-furnace blower is driven by Diesel engines. The high cost of power dictated several refinements, for the controlling of waste, that would not be worth while at a plant where power is cheaper. Among these is the separation of the circuits in all the important buildings into a day system and a night system. In the day-time a few lights are always needed for dark corners, and also outlets for extension cords. These are all on a 'day' circuit. The great bulk of the lights, which are required only at night, are on a 'night' circuit. These two circuits are separated at the main junction-box for each building; when the foreman for day-shift comes on duty he opens the 'night' circuit, thus preventing useless waste of current irrespective of what is done with the individual switches.

Another detail of design that has saved many operat-

ing delays and other more serious trouble is a system of double power-lines. To all the individual important circuits in the plant, such as converters, cranes, and transportation systems, two power-lines are run, one around the north end of the plant and one around the south end. These two lines are tied to the intake and the feeders by double-throw switches, as indicated on the accompanying sketch. In case of trouble on the operating line the man in charge does not delay to discover the trouble; he merely throws the two sets of double-throw switches, a matter of a few minutes only, operation is resumed, and the trouble is hunted down at leisure. H. A. Reutschi, chief electrician, stated that this system has been found invaluable, and that it has saved many times the cost of the double installation. When the Arizona Power Co. lines go, the United Verde turbo-generator sets take the load.

To aid in obtaining quick attention to trouble, all stations for electricians are on an individual telephone system direct to the electrical shop, where some one is always on duty. The shop has a telephone switch-board and the operator can act as 'central' to connect the electrician's stations, either with each other or with an outside line. Trouble is telephoned to the electrical shop by the shift-boss or foreman, where the man in charge, who has a chart showing the position of every electrician at that moment, calls up the most available man and sends him to attend to the work.

The switchboard in the power-house is of the 'remote control' type. On the main floor is the polished slate

ARRANGEMENT OF DUPLICATE POWER-LINES

board of 39 panels, wired for 2500 volts. The levers on this board are mechanically connected to oil-switches on concrete panels in the basement. As is customary the oil-switches are protected by disconnecting knife-switches,

to safeguard doubly men working on the line, or in case the oil-switches need repairing.

The air for the blast-furnaces is furnished by the following equipment, at an average pressure of 31 ounces:

Electric drive:

One No. 11 Root blower, 48 by 132, rated at 401 cu. ft. per revolution to $2\frac{1}{2}$ lb. Driven by one G. E. 500-hp. induction motor, type 1-16-500, 2200 volt, 442-450 r.p.m. Gear-connected.

One No. 11 Root blower 48 by 99, rated at 300 cu. ft. per revolution. Driven by two motors, each Westinghouse 200-hp. induction, type CCL, 440 volt, 254 amp., 495 r.p.m.

One No. 9 $\frac{1}{2}$ Root blower, 48 by 99, rated at 224 cu. ft. per revolution. Driven by one Westinghouse slip-ring induction motor, type CW, 2200 volt, 585 r.p.m.

One No. 11 Root blower, 48 by 132, rated at 400 cu. ft. per revolution. Connected by rope-drive to one Westinghouse slip-ring induction motor, type SP, 2200 volt, 315 r.p.m.

Steam drive:

One No. 11 Root blower, 48 by 132, rated at 400 cu. ft. per revolution. Direct-connected to an Allis-Chalmers Corliss 16-32 by 36 cross-compound horizontal condensing engine. Steam at 150 pounds.

Diesel-engine drive:

One No. 11 Root blower, 48 by 99, rated at 300 cu. ft. per revolution, connected by rope drive to two vertical Diesel engines, triple cylinder type, 16 by 24 in., 225 hp. each. This blower is kept as a spare. Air for the Diesels is furnished by two Ingersoll-Rand three-stage compressors, 8-5-2 $\frac{3}{4}$ by 8, 185 r.p.m., compressing 86 cu. ft. of free air per min. to 1200 lb. The starter and the compressor drive is a Westinghouse 50-hp. slip-ring induction motor, 2200 volts.

The air for the converters is furnished by the following equipment, at an average pressure of 16 lb. All are steam driven.

Nordberg blowing-engine, horizontal cross-compound condensing duplex. Steam end 60-28 by 48. Uses steam at 175 hp. with 100° super-heat. Air end 60-60 by 48. Capacity 24,000 cu. ft. of free air per min. at 81 r.p.m. Fly-wheel 60,000 lb., 18 ft. diameter.

Nordberg blowing-engine, horizontal cross-compound duplex. Steam end 32-64 by 54. Uses steam at 120 lb. Air end 60-60 by 54. Capacity 20,000 cu. ft. of air per min. at 56 r.p.m.

Southwark blowing-engine, horizontal cross-compound duplex. Steam end 28-52 by 60. Steam at 125 lb. Air end 60-60 by 60. Capacity 20,000 cu. ft. at 60 r.p.m.

Southwark turbo-blower, Rateau-Smoot type, water-cooled. Steam at 125 lb. Capacity 25,000 cu. ft. at 2500 r.p.m.

General high-pressure air is furnished by:

Ingersoll-Rand two-stage compressor, Class PRE 2, 29-17 $\frac{1}{2}$ by 21. Capacity 2470 cu. ft. of free air to 100 lb. at 180 r.p.m. Direct-connected to a G. E. self-starting synchronous motor, 2200 volt, 180 r.p.m., 434 brake horse-power.

Nordberg compressor, steam driven, two-stage cross-

compound condensing. Steam end 22-42 by 48, Corliss type. Steam at 100 lb. Air end 19-32 by 48. Capacity 2500 cu. ft. of free air to 90 lb. at 57 r.p.m.

There are two generators, driven in parallel, to furnish current for all purposes when the lines of the Arizona Power Co. fail, namely:

One Allis-Chalmers 2000 kw. turbo-generator, Parsons type, condensing. Steam at 150 lb., 2300 volt.

One Allis-Chalmers 1500 kw. turbo-generator, Parsons type, condensing. Steam at 150 lb., 2300 volt, 3600 r.p.m.

All AC machine fields are excited by

One Allis-Chalmers turbo-exciter, 125 volt, 280 amp., 3600 r.p.m.

One Westinghouse motor-generator. Generator 125 volt, 200 amp., 1120 r.p.m., 25 kw. Motor, induction, 440 volt, 40 hp., direct-connected.

In case of trouble with the transformers, a 440-volt current can be furnished directly by a Westinghouse 500 kw. turbo-generator, 657 amp., 3600 r.p.m. Direct-connected to a Parsons turbine.

Direct current for railway and general D. C. lines is furnished by two Westinghouse motor-generator sets. Each generator is 250 volt, 800 amp., 200 kw., 600 r.p.m., driven by a synchronous motor, 440 volt, 290 horse-power.

The crane has a span of 56 ft. 11½ in., and a capacity of 20 tons with a factor of safety of five.

THE MACHINE-SHOP now handles not only all repair work for the smelter, but all heavy repairs for the mine, the present shops at Jerome being inadequate for more than light work. This is only a temporary arrangement, as with the completion of the new surface plant at Jerome, the shops at the mine will be able to do all the mine work, and the machine-shop at the smelter will be used only for smelter work.

One of the first features noticed on entering the shop is that most of the machines are driven by counter-shaft. This is because almost all the present equipment has been in use several years; at the time it was purchased, individual drives were just beginning to come into vogue, and the management at that time decided in favor of the older system. J. A. Magill, the foreman, who courteously showed me through the shop, believes that individual drives would be better, thus confirming my observation as to the trend of recent practice.

There are two line-shafts, each driven by a 20-hp. Westinghouse motor, type MS, 440 volt, 60 cycle, 845 r.p.m. One line-shaft drives the lathes; the other drives the milling-machines, drill-press, planers, etc. Two machines are recent installations and have individual drives, namely, the boring-mill and the power-press. It has been found that the line-shaft driving the milling-machine and planers is a little short of power when the big planer is run.

The equipment is as follows:

In general big work, an old model 72-in. lathe of unknown make.

One 24-in. by 48-in. Le Blond heavy-duty gap lathe. Bed: closed, 14 ft.; open, 20 ft.

One 24-in. Hendey lathe, 14-ft. bed.

One 18-in. Prentice lathe.

One Detrick & Harvey Machine Co. open-side planer, 48-in. by 48-in. by 16-ft. bed.

One 28-in. Crank shaper.

One 20-in. Gould & Eberhardt shaper

One Le Blond No. 4 Plane milling machine.

One 6-ft. radial drill-press, full universal, made by American Tool Works Co.

One Cincinnati drill-press, 24-in. table.

One 60-in. Gisholt boring-mill. This has an individual drive, a Westinghouse CS 7½-hp. motor, 440 volt, 855 r.p.m.

One 400-ton power-press, used principally for forcing car-wheels on axles. This also has an individual drive, a G. E. type, 1 10-hp. motor, 440 volt, 865 r.p.m.

One Acme single-head bolt-cutter.

In addition to this major apparatus, there are the usual auxiliary grinders, power hack-saws, and similar equipment.

The tool-room is equipped with a No. 3 Cincinnati universal milling-machine; a B. & S. No. 2 Universal grinder; an 18-in. American tool lathe; and an 18-in. Aurora Tool Works drill-press.

Mr. Magill, in commenting on the suitability of the entire shop to the needs of the smelter, stated that in general it performed its work well. He has found that the lathe sizes are not sufficiently different, and believes that a 16-ft. boring-mill, with a 72-in., a 48-in., and a 24-in. lathe, would give a better range. A slotting-machine, especially for key-ways, would be an improvement. All internal key-ways must now be cut on a shaper or planer; external key-ways are cut on the milling-machine. In the tool-room a simple device that has been much used is a 'backing-off' attachment for automatically putting the clearance on reamers and taps. This is attached to the 18-in. lathe, and when once adjusted as desired requires no further attention.

MONAZITE is essentially a phosphate of the cerium earths, but its commercial value is due chiefly to the presence of a variable amount of thorium, the oxide of thorium, according to a publication issued by the British government. This is extracted from it by chemical treatment and marketed in the form of thorium nitrate for use in the manufacture of gas-mantles. The mineral is found in the form of grains, usually of a honey-yellow color, in beach and river sands. Commercial supplies of the sand were first obtained from the beach sands of the Brazilian coast; but deposits of a closely similar character were found some years ago on the coast of Travancore in southern India, and they have since been found in Ceylon. Monazite sand can be easily identified as a rule by its color, the well-rounded form of the grains, its high specific-gravity (about 5.2), and weakly-magnetic character. In consequence of this magnetic character it can usually be isolated from the other heavy minerals by means of an electro-magnet. Monazite shows a characteristic absorption spectrum, but is best identified by the physical characters already enumerated, and by the fact that it yields a phosphate reaction.

Labor the Holder of the Nation's Wealth and Income—I

By W. R. INGALLS

*This study was instituted with the intention of showing the amount of the annual income of the American people, its division between what are commonly classed as capital and labor, and its further division among the classes of labor. It proved impossible to carry out this ambitious plan in its entirety owing to the absence of essential data.

Dr. Arthur L. Bowley recently published a similar analysis of the national income of Great Britain before the War. Although he made a far better study for British conditions than I have been able to do for American, he encountered similar difficulties, and remarked that "material for such a task is of that unco-ordinated, incomplete, and sporadic nature which is familiar to all those who have tried to obtain general results from official statistics". The same remark may be made with respect to American official statistics. It is not satisfactory that out of the great mass of statistics that are collected and published in Washington there is nothing given that ought to be a fundamental figure, namely, the amount of the total national income, nor even sufficient data to permit that figure to be deduced.

In the greatest economic disturbance of the world's affairs that there has been since the Thirty Years' War, and possibly that there has ever been, nothing but imperfect statistical information respecting the wealth and income and earning capacity of the countries of the world exists. John Maynard Keynes in his book on the 'Economic Consequences of the Peace', the most important economic production reviewing the consequences of the War to Europe, and we may say to the world, shows that the conference in Paris did not possess adequate information (and for that matter did not pay proper attention to what it had).

In this paper I show that we do not have in this country any good inventory of its wealth, any satisfactory computations of annual gross and net income, any regular enumerations of either the total number of workers in the country or their classification according to industries and occupations, any comprehensive data as to their earnings. I believe that this paper is the first to draw attention to this, and offer even rough estimates for the situation in recent years. Previous to this paper I do not believe that there was ever any computation of the quantity of all the basic commodities produced in the United States, and even now there are no data of the quantity of products exported, the only summaries of the elaborate statistics of the Department of Commerce and Labor being in terms of dollars, which, in view of the extraordinary rise in prices since 1914, afford but little idea of what has really happened.

Although the study, begun in March 1919, whereof the results are summarized in this paper was side-tracked for several months for the reasons stated above, it has seemed to me advisable, in view of the great importance of the subject and the bearing of certain revelations that can be made with assurance, to publish the general outline in spite of its fragmentary nature and unsatisfactoriness as a whole. Let it be understood therefore that I am not offering dogmatically everything that is to be found in this paper, but am presenting it simply as a contribution that will be indicative and suggestive. Nevertheless, I feel a confidence that my conclusion, especially as to the capitalistic share of the produce of industry is substantially correct. It is not far out of line with what Bowley has deduced for Great Britain, and is almost identical with data for Australia.

In an editorial in 'The Age' of Melbourne, September 5, 1919, it was stated that "the figures of the Commonwealth statist show that our total national income is £240,000,000, and of this £159,000,000 is spent in wages and salaries, and £81,000,000 is paid as a 5% income on property. In the aggregate rewards of our Australian production the wage-earners and income receivers under £500 get four-fifths of the total, and the 'fat men' only one-fifth". Compare these data with figures in my summary for the United States, which follows immediately.

The main conclusions of this paper are the following: The fixed wealth of the United States in 1916 was about \$260,000,000,000, whereof about \$30,000,000,000 was in stocks of goods and all the rest in real estate, railways, etc. The population of the country was about 102,500,000 souls, of whom about 41,000,000, men and women, were workers, about 14,000,000 of them being farmers. The total national produce was about 1,200,000,000 tons of goods, worth from \$45,000,000,000 to \$50,000,000,000. Out of that produce a group of people aggregating a little more than 400,000, who received incomes in excess of \$3000 and paid income taxes, got about \$7,900,000,000. Less than one-half of that was derived from investments and more than one-half came from the personal efforts of this class. Persons enjoying income of less than \$3000 received about 44% of the dividends paid by corporations and a much larger proportion, perhaps 75%, of the Government, State, municipal, and corporate interest payments. There remained from \$23,000,000,000 to \$28,000,000,000 to be divided among 27,000,000 non-agricultural workers, who received an average of somewhere between \$855 and \$1040 each. Among the great classes of workers there is a wide difference in earnings. The farm-hand in 1916 averaged about \$400, the factory worker \$675, the steam-railway man \$886, and the metal miner \$1250. Some classes probably averaged higher wages than the metal miner.

*From 'The Annalist', of September 13, 1920.

The purely capitalistic return, that is, profits, interest, and rent, upon the wealth of the country cannot be determined, but apparently is only a small percentage, certainly less than 5% on the fixed wealth. If the non-agricultural wage-earners in 1916 could have appropriated all the income of the class of people receiving more than \$3000 they would have added less than \$300 to each of their own incomes, but in fact they could have done no such thing, for the large sum ascribable to the personal efforts of business and professional men would not have been available for division.

Since 1916 the population of the United States has been increasing at the rate of about 1,700,000 per annum, but the aggregate production of goods has increased scarcely any. Out of the substantially stationary production, much has been wasted in warfare and much has had to be supplied to the people of Europe. The quantity available per person in this country has therefore diminished. The talk about labor henceforth participating to a greater extent in the produce of industry is mostly nonsense, for labor already gets all that may be divided, and the only way it can get any more is to produce more. When labor thinks that it is getting more of the produce of industry by extortionate strikes, as a whole it is doing no such thing. The quantity of goods consumed by the 400,000 income-tax payers is relatively insignificant. What really happens is that one class of labor, in order selfishly to satisfy itself, diminishes the ability of other classes of labor to obtain their needful share of goods. Manifestly conditions that enable some wage earners to bid shoes up to \$12 per pair do not greatly trouble people in the tax-paying class, but do prevent many other wage-earners from having any shoes at all, or else having them at the expense of something else.

Amid the idealism of the day in the preaching of industrial democracy and the uplifting of the downtrodden these conclusions may appear cold and sterile, but they are not. If people can get into their heads the idea of the division of goods instead of the division of dollars they may become less extravagant in the use of goods and more fruitful in the production of them. The evils of the time and their corrective are condensed in this formula.

There is at present a worldwide unrest among the people of the civilized world, which may be expressed in the most temperate way as the desire of the wage-earner for a larger share of the product of industry. This statement implies that heretofore the wage-earner has not been getting either a fair or a satisfactory share; and that there is a further portion of the product of industry that he ought to get, can get, and proposes to get. Sociologists have sanctioned this view and this program. Politicians have bowed to it. Even industrial leaders, to a considerable extent, have conceded it. There have been few to deny it, except economists of the coolly calculating school, who have pointed out that people cannot divide among themselves more than they have got.

Illuminating object-lessons have passed with scant attention. Among these have been the cases, like that of the railways of Great Britain, where the workers in an industry have demanded and have been granted more

than the industry produces, the deficit being paid out of the national purse. Yet it should be obvious even to the humblest intellect that if every industry should be put upon such a basis there would be nothing in the public purse out of which to pay deficits, which is simply to say that all of the people cannot get any more than they earn, although one class may do so temporarily at the expense of other classes. There is, without doubt, a theory that something more can be taken out of what are called the capitalistic and employing classes, which indeed is the only possible meaning in the demand "for a larger share of the produce of industry". No sensible person will dissent from the idea that it will be useful to examine how much there is in it for the wage-earner before undertaking to disturb existing conditions.

I dwelt upon this subject in an address to the Mining and Metallurgical Society of American in January 1919, in which I asserted that in 1916 American wage-earners received about 80% of the \$50,000,000,000 produce of American industry in that year, their earnings being divided among 40,000,000 workers at the rate of about \$1000 each and that the sum of \$10,000,000,000, which was the share of capital, was only about 4% on the wealth of the nation, estimated at about \$250,000,000,000. I stated that those estimates were very rough, but maintained that they were probably near enough to give a reasonable idea respecting the division of the produce of industry. Since then I have continued study of this subject and am now able to give some more accurate and illuminating indications. I take the year 1916, that being the latest for which sufficient figures are available.

Before entering upon any consideration of the gross revenue and net earnings of the country it will manifestly be desirable to get some idea of what is the wealth of the country, its capital, so to speak.

The wealth of the United States, chiefly in farms, factories, forests, railways, and other public improvements, developed mines, houses, etc., has been commonly estimated at \$230,000,000,000 to \$250,000,000,000 as of 1916. It is obviously impossible to make anything like a complete inventory and valuation of such property, but there is more or less reason to believe that even the higher of these figures is too low.

The basis for most calculations on this subject is the bulletin of the Bureau of the Census on 'Estimated Valuation of National Wealth', published in 1915 and giving data for 1912. Estimates for later years are commonly computed on the principle of proportionate increase. Such results may be highly erroneous, especially when it be considered that not only the multiplier may be wrong but also the base that is multiplied. Figures once given in a Government report are too often assumed to be specific and accurate. Critical examination of the figures giving the details of the national wealth in 1912 reveals that they were in many cases mere estimates multiplied from some previous base and should not be accepted upon any other understanding. I have tried to make an estimate of the national wealth in 1916 upon the principle of an inventory. The census figures for 1912 are given for comparison.

My estimates for 1916 are very rough, are offered but tentatively, and are freely open to criticism, suggestion, and revision. They serve merely a purpose in showing the forms in which national wealth exists, and about how much there is in each form. This appears in the accompanying table.

Wealth of the United States		
	1912	1916
Real estate	\$110,676,333.071	\$150,000,000,000
Mines		8,000,000,000
Live-stock	6,238,338,985	7,235,000,000
Farm implements	1,368,224,548	1,675,000,000
Manufacturing machinery and tools	6,091,451,274	8,000,000,000
Gold		3,000,000,000
Silver	2,616,642,734	1,000,000,000
Railways	16,148,532,502	20,500,000,000
Trolley-lines	4,596,563,292	5,000,000,000
Telegraph and telephone	1,304,685,743	1,500,000,000
Pullman cars	123,362,701	130,000,000
Ships		1,000,000,000
Canals	1,491,117,193	1,000,000,000
Irrigation enterprises	360,865,270	400,000,000
Water works, privately owned	290,000,000	300,000,000
Light and power, privately owned	2,098,613,122	4,500,000,000
Gas plants		3,500,000,000
Furniture, carriages, etc.	8,463,216,222	9,220,000,000
Clothing, jewelry, etc.	4,295,008,593	5,120,000,000
Stocks of goods	21,576,065,840	29,520,000,000
Totals	\$187,739,021,090	\$260,600,000,000

I am inclined to think that my estimate for 1916 is still too low. For example, ships are reckoned at only \$100 per ton, while the United States Emergency Fleet Corporation is now holding them at \$200 per ton. The conservative character of other estimates will appear from the explanatory notes that follow.

No allowance is made for the foreign investments of the United States, which even in 1916 were considerable. However, the huge loans to foreign governments did not begin until 1917, although the Anglo-French and other issues had been taken previously.

American investments in mines, railways, and other fixed property in Mexico and South America were, of course, considerable.

The foregoing estimate of the wealth of the United States pertains only to the fixed wealth of the country. There is also a large intangible wealth, which represents work done and stored up just as much as railways do. Thus the publishing business of the country is worth vastly more than the real estate, machines, etc., that are used in connection with it. The mere organization for the purpose of conducting all kinds of business is a form of intangible wealth that has been acquired only by vast expenditure of work and is immensely valuable. In some respects such intangible wealth ranks among the strongest forms of property. A house may be destroyed by fire, suddenly and within a few hours, but the fame of a newspaper which maintains its circulation is apt to be a lasting thing. The value of intangible property is well recognized among persons experienced in business, but is not understood by the inexperienced.

BORON and its compounds find a use in the copper industry. They act as scouring agents in molten copper, and copper castings of high electrical conductivity and dense quality are obtained by their use. Boron is also used in the manufacture of aluminum bronzes of great strength, in hardening and strengthening aluminum castings, and in the manufacture of nickel castings.

Cobalt

*Cobalt minerals are uncommon except in the Cobalt district, Ontario, Canada, where they occur in ores that are worked for their silver content, the cobalt produced being a by-product. The smelting and refining of this ore has recently been described by Sydney B. Wright ('Mining and Scientific Press', January 25, 1919, p. 125). As these ores are brought to various smelters, according to changes in smelting contracts, the material comes on the market from different places at different times. In the main it is marketed as cobalt oxide; the metal is produced from the oxide by reduction. The principal use of the metal is in the patented alloy known as stellite (about 80% cobalt), which is used as a high-speed cutting-tool in place of steel (Transactions A. I. M. E., Vol. 44, p. 573). Cobalt is also used in a high-speed tool steel which contains 4% cobalt and 16% tungsten. It is also claimed that it can be used as a substitute for nickel in plating, the rate of deposition being faster than with nickel and a thinner coating giving equal protection. Cobalt compounds are used for coloring pottery and glass, to which they impart the shade known as delft blue, and also certain purple shades.

The cobalt output of Canada in 1916, according to official statistics, was 841,859 lb.; of which 215,215 lb. was in the form of metal. The oxide produced amounted to 670,760 lb., and there were smaller quantities of sulphate, carbonate, and hydroxide of cobalt. Up to the present time the supply of cobalt available from the Canadian ores has been abundant to meet all demands. There are only two sources of cobalt in the United States that are of any importance. A deposit at Blackbird, Idaho, is owned by the Haynes Stellite Co., which has erected a plant for the production of cobalt concentrate. Cobalt, nickel, and copper sulphides occur in association with lead ores at Fredericktown, Missouri, and some cobalt oxide is now being produced by the Missouri Cobalt Co. The price of cobalt metal has averaged about \$2 per pound in the United States.

THE U. S. Bureau of Mines has issued a bulletin in which it is said that numerous accidents are still being reported that have resulted from the delayed explosions in drill-holes. Some of these accidents have been due to retarded burning of the fuse, causing the charge to explode after the miners had returned to the face, but the majority have been caused by the miners drilling or picking into unexploded explosives, either in unexploded holes or in broken rock. Although the industry has been cautioned by the Bureau of Mines, manufacturers of explosives, and other agencies regarding the care that is necessary in the handling of explosives, yet reports of these accidents are still being received and many of the accidents are fatal. They occur in spite of the best efforts of the mine officials and men, but many of those that have been reported could have been avoided.

Platinum

*The following statement regarding platinum is issued in response to numerous inquiries. In preparing it a number of authorities have been consulted, the publications of James M. Hill of the U. S. Geological Survey having been especially drawn upon.

PHYSICAL PROPERTIES. Platinum is a white metal with a grayish tinge, and takes a high polish but one less brilliant than silver. It is malleable and ductile, and can be rolled into thin sheets and drawn into fine wire. These properties are impaired by the presence of impurities. It has a specific gravity of 21.3 and a hardness of 4 to 5, being harder than copper, silver, or gold. It melts at about 1710°C. The atomic weight is 195.2.

CHEMICAL PROPERTIES. Platinum is not acted on by dry or moist air even when heated to high temperature. It is not attacked by hydrochloric, nitric, or sulphuric acid, but when alloyed with silver, copper, lead, zinc, and some other metals, it is partly dissolved by nitric acid. At high temperature it is attacked by fused alkalis in the presence of air and by potassium and other nitrates when air is excluded. It is also attacked at high temperature by carbon and by silica in the presence of carbon. Platinum vessels should, therefore, never be heated in contact with solid fuel. Cyanides likewise attack it.

USES OF PLATINUM. Owing to its resistance to the action of acids and most chemical agents even at high temperatures, and to its high melting point, it is in extensive use for the manufacture of crucibles, basins, foils, wire, etc., and for chemical laboratory work. A large quantity is also used in the construction of apparatus for the catalytic manufacture of concentrated sulphuric acid. A considerable amount is consumed in the electrical and dental industries and in the preparation of salts, notably the chloride for photographic work. There has been also a large demand for it by jewellers.

ALLOYS AND SUBSTITUTES. The making of alloys of platinum and substitutes to take the place of platinum has been seriously studied and to some extent platinum has been replaced. There is no question that other combinations or substitutes will be developed in the future, but no substitutes to take the place of the platinum contact points in high-grade magnetos and for numerous other purposes has so far been found. Alloys of gold and palladium which cannot be told from platinum by ordinary physical properties, are now used in dentistry, jewelry, and to a limited extent in chemical apparatus.

ORES OF PLATINUM. Platinum occurs native in alluvial deposits derived from the disintegration of primitive rocks in the form of grains approximately spherical but less often flattened. Nuggets of large size are rare, but a number of small nuggets are found in the Ural region and one weighing 270 oz. is recorded by Hautpick as

having been found in the placers of Mt. Katchkonara, in the northern portion of the platiniferous district of the Ural, Russia. A still larger one, weighing 21.64 lb., is in the Demidoff museum, at Petrograd. The most extensive deposits of platinum are the alluvial sands of the Ural. They are contained within a length of about 80 miles along the central part of the chain in the province of Perm, the principal centres of the placers being at Blogodat on the eastern and Niji Tagilsk on the western slopes. This field furnishes the main part of the world's production of the metal. In Colombia, on the Condoto and upper Atrato rivers, are important platinum deposits, which are attracting considerable attention at this time. The production of platinum from Colombia is steadily increasing. Platinum is associated in the placers chiefly with gold, iridosmine, chromite, magnetite, zircon, ilmenite, corundum, and quartz. The admixture of gold is variable, ranging from 2 to 3% in some districts to as much as 75% or more in others. Among the metals of the platinum group are iridium, palladium, and rhodium, which are intimately combined with platinum and can be separated or determined by careful chemical analysis.

OCCURRENCE. The mother-rocks of platinum are of the basic igneous type, such as peridotite, pyroxenite, and dunite. The peridotites and pyroxenites are dark-gray to black heavy rocks composed principally of black or dark-green iron-magnesium silicates, pyroxene, augite, and hornblende, olivine, plagioclase feldspar, chromite, ilmenite, and magnetite. Dunites are composed principally of olivine with some chromite. There is every gradation between these types of rocks and the less basic rocks. A characteristic of the basic rocks is their tendency to alter to serpentine, a soft greasy fibrous mineral of olive-green to black color that once seen is readily remembered. Attempts to trace platinum to its source have proved successful in Russia, Spain, and Canada, but no deposit of platinum in the mother-rock has been found of commercial grade under normal conditions. It is possible, but does not seem probable, that bodies of platiniferous rock may be found in the United States rich enough in platinum to be worked under present conditions. It should be recalled, however, by all persons searching for platinum ores that the assay for platinum is difficult and apparently cannot be successfully made by all commercial assayers. It is therefore strongly recommended that samples of supposed platiniferous ores be sent only to the most reliable analysts.

BLACK SAND. Most of the platinum produced in the United States is recovered as a secondary mineral from placer operations and from the electrolytic refining of gold bullion and blister copper. From time to time the beach-sand of Oregon and northern California has been exploited by promoters on the basis of the gold and platinum content. A successful method of mining this sand must be based upon a thorough prospecting of the

*Issued by U. S. Bureau of Mines.

deposits. Investigation has shown that in general the black-sand deposits are disappointing in both quantity and quality, and while in a few places there has been sufficient surface concentration to permit of small mining operations, these deposits rarely contain enough gold and platinum or occur in adequate extent to be operated at a profit.

METALLURGY. In general, the crude platinum of the Western placers is found in relatively small scales or flakes, some larger than one-eighth inch in diameter, but the majority less than one-sixteenth inch in size, many being under one thirty-sixth inch. These flakes have a tendency to elude capture in the ordinary miner's sluice and probably a large part of the flake gold and platinum has hitherto been carried in suspension to the tailing-piles. Undercurrents in the sluice-lines have added to the saving of the fine gold, but they are not entirely satisfactory as savers of gold and platinum. Burlap and canvas tables have also been used with some success. Many types of specially designed machines have been tried and discarded, though undoubtedly some have merit and a few are making a fairly satisfactory saving. In the treatment of beach-sands concentrating tables are also used.

The loss of fine gold and platinum in ordinary hydraulic operations is due to several causes, among which may be mentioned running pulp too fast and agitating it too much to permit settling, failure to clean up often enough to prevent packing of riffles with consequent formation of smooth slopes over which metals readily flow under pressure, and failure to provide settling-boxes for fine material carried in suspension. On some of the gold-dredges various devices to effect a closer saving of the fine gold and platinum lost in the tailing have been tried. The most successful has been the Neill jig and the Hardinge mill, which are in operation on two of the Natoma dredges in California. It was found on some of the other dredges of this company and of other companies in the State that the recovery effected by this tailing-plant was not sufficient to justify the expense of its installation. In other words, there was very little platinum or fine gold in the tailing. In addition to the platinum recovered from placer operations, some platinum and palladium is recovered from the platiniferous ores of the Boss mine in Nevada and the Rambler mine in Wyoming. These ores are concentrated locally and sent to refiners for final treatment. The United States Smelting & Refining Co., and the Irvington Smelting Works buy ores. The crude platinum is separated from the sand and gravel, as already stated, by a series of washing processes. If any gold is present it is obtained in the concentrate together with the platinum. In Russia the gold is removed by repeated amalgamation with mercury in wood, iron, or porcelain bowls, about 10 to 30 lb. being treated at a time. The crude platinum is then almost all exported to be refined abroad, not more than about 2% being refined in the country.

REFINING. The crude platinum can be refined either by dry or by wet methods. When dry methods are em-

ployed, any iridium and rhodium present will remain with the platinum; on the other hand, when wet methods are used, the resulting platinum will be pure. A combination of the two methods is also employed. The wet method consists essentially in dissolving the crude platinum in aqua regia, precipitating the platinum as ammonium platinichloride, heating the precipitate to redness, forming spongy platinum, and fusing the latter by the oxyhydrogen blow-pipes in a furnace constructed of blocks of lime. The refining of platinum ore is a complicated matter.

The principal buyers of crude platinum in the United States are the following firms:

American Platinum Works, Newark, New Jersey.
Baker & Company, Newark, New Jersey.
Belais & Cohn, 13 Dutch street, New York City.
Bishop & Company, Malvern, Pennsylvania.
Pacific Platinum Works, Los Angeles, California.
Shreve & Company, San Francisco, California.
H. A. Wilson Company, Newark, New Jersey.
S. S. White Dental Company, Philadelphia, Pennsylvania.

HINTS FOR PROSPECTORS. The placer deposits containing platinum are all, so far as known, in the vicinity of areas of basic igneous rocks, and in any search for new deposits of platiniferous gravels the first step is to find outcrops of peridotite, pyroxenite, dunite, or serpentine. When these have been found, the gravel in streams flowing out should be washed to ascertain if platinum is present. The natural concentrate found in alluvium containing platinum is usually rich in chromite and olivine. The character of the rock particles often gives a clue to the source from which the gravel was derived. Platinum, as it occurs in a placer concentrate, is ordinarily a silvery white metal that could be confused only with silver, and possibly pieces of iron or steel. It can be distinguished from both of these metals, as they are soluble in dilute nitric acid; crude platinum can be dissolved only in concentrated aqua regia, a mixture of three parts of hydrochloric (muriatic) acid and one part of nitric acid. In some placer deposits the grains of platinum are coated with a dark film and somewhat resemble the grains of the dark minerals chromite, magnetite, or ilmenite, from which they are separated by careful panning, as the specific gravity of platinum is greater than that of any of those minerals.

Platinum will not amalgamate with quicksilver alone, but will amalgamate if sodium is added. In ordinary quicksilver the flakes of platinum float on the surface and can be removed. If sodium amalgam is used, the platinum may be separated from gold by agitating the amalgam with water until all the sodium is used up to form sodium hydroxide; then the platinum will come out on the surface of the amalgam, provided, of course, the amalgam is sufficiently liquid. Platinum can be scratched with a knife. It is so malleable that it can be pounded, without heating, into very thin sheets. It is practically infusible; the grains cannot be melted together as particles of gold can.

A relatively simple chemical test can be made to determine platinum: The metallic particles are dissolved by boiling in concentrated aqua regia, allowing the resulting solution to remain on the stove until dry. The residue is dissolved in hydrochloric acid and evaporated by boiling until the solution is thick but not quite dry. This mass is dissolved in distilled water and a few drops of sulphuric acid and of potassium iodide solution are added, which, in the presence of platinum, causes the solution to turn a characteristic wine-red, if much of the metal is present, or to a reddish pink in the presence of small quantities of platinum. The test outlined above is fairly delicate, but it cannot be used to detect traces of platinum in the presence of large quantities of iron or other elements.

A second test may be applied to the aqua regia solution after the re-solution in hydrochloric acid outlined above. In this test potassium chloride is added to the solution, which precipitates yellow crystals of potassium platinate chloride, if platinum is present.

A third test may be applied: Add ammonium chloride to the aqua regia solution; this will precipitate yellow crystals of ammonium platinate chloride, if platinum is present.

The precipitates from the second and third tests are insoluble in alcohol, but are soluble in water, and may be reduced to platinum sponge by heating.

All these tests are comparatively simple and positive when made on single grains, but they cannot be relied upon when various other elements are present in the material tested. It is, therefore, recommended that their use be restricted to grains of a single mineral picked from the concentrate obtained by panning a sample of either rock or gravel.

Radium

*The United States is the foremost radium-producing country in the world. This ascendancy has been gained notwithstanding that 500 tons of American ore is required to produce the one gramme of radium that has been obtained from five or six tons of European ore. A gramme is about a thimbleful.

The first radium produced in the United States was obtained in 1913 in the laboratory of the Standard Chemical Co. Since then the production of this company has been as follows:

	Radium element grammes
1913	2.1
1914	9.6
1915	1.7
1916	5.0
1917	7.0
1918	13.6
1919	11.8
Total	50.8

Up to the present time it has produced almost one-half of the estimated supply in existence.

Radium preparations in the United States are spoken

*Abstract from an article by Hamilton Foley in the 'Chemical Age'.

of and measured in terms of radium element. Until recently European scientific men have adhered to the term radium bromide. Crystalline radium bromide when pure contains only 53.6% of radium element. There was no common standard. The original method of measuring radium, consisted in comparing its activity with that of uranium. During the 14 years this system of measurement prevailed scientific men spoke of radium as "two million times more active than uranium". Trained minds, of course, understood that what was meant was that the quantity of electrical energy emitted in the rays of the radium, small though it was, was two million times greater than that contained in the rays from uranium. Such a ratio of comparison was entirely unsuitable for use especially with small quantities, and about 1912, by common consent, Madame Curie was asked to prepare what would be an international radium standard. This is deposited at Paris. Duplicates are in the leading capitals of the world, and radium preparations are now measured by comparing the electrical energy carried by the gamma rays from the preparation to be measured with the energy carried by the gamma rays of the international standard, or one of the certified duplicates of it. In 1914, the U. S. Bureau of Standards obtained a certified duplicate of the international radium-standard and practically all quantities of radium in this country have been measured by comparison with it.

In the industrial world interest in radium has always been limited by the small amount available. This was especially true of the ten years following its discovery. During that period some attempt was made to use the action of radium in causing a spontaneous and continuing luminescence in substances such as zinc sulphide, to make what is called luminous paint, but prior to 1913 this effort was practically negligible. Radium and radium minerals are not generally luminescent. Tubes containing radium glow from impurities present which the radiations from the radium cause to give light. The War created a most unexpected demand for radium. The necessity of illumination that would not betray presence to the enemy in the various branches of the fighting-service made radium-luminous material the most satisfactory and dependable light. The demand for the luminous watch-dial alone raised one use for this material to a fair-sized industry.

Therapeutically, there has been a gradual and steady increase in the use of radium since 1912. The earlier over-enthusiastic statements of the value of radium in the treatment of cancer have not been wholly confirmed and radium is far from being the panacea in the treatment of diseases. Nevertheless surgeons throughout the world are gradually admitting that radium is a necessary adjunct to the treatment of cancer.

THOSE who are called upon to do blasting should be familiar with the publications of the U. S. Bureau of Mines dealing with explosives. One of the best papers is Bulletin 80, 'A Primer on Explosives for Metal Miners and Quarrymen'.—U. S. Bureau of Mines, Reports and Investigations.

The McFadden Bill

*In an interview given out on October 7 by Representative Louis T. McFadden, Chairman of the Committee on Banking and Currency of the House of Representatives, he asked the following pertinent question with reference to the gold situation: "Is the United States to continue to ignore the problem of gold production, thus permitting the British Empire to gain an unquestioned supremacy?"

An estimate of the gold production of the United States based on the output for the first six months of this year indicates that the production for 1920 will be less than half the amount produced in 1915. In 1915 the United States produced 21.5% of the total world's gold output, and the British Empire 63.7%. In 1919 the United States produced but 16.6% of the world's gold output, while the British Empire produced in excess of two-thirds. Since July 24, 1919, the British Empire has been paying an exchange premium as high as 50% to the gold producers of South Africa, where the bulk of the British gold is produced, while in the United States no assistance has been rendered the gold-mining industry. This year the contribution of the United States to the gold production of the world will probably be not more than 12%, about half of that which it contributed in 1915, while the stimulating effect of the exchange premium will probably increase the quota which the British Empire will contribute to 75%.

As compared to 1914, the purchasing power of the dollar in terms of all commodities in 1919 was 47 cents. The gold producers' ounce in 1914 had a purchasing power of \$20.67, whereas during 1919 the same ounce could purchase in terms of all commodities but \$9.70. Since the price of gold is fixed by statute at \$20.67 an ounce, the gold producer is in the same position as a person who received the same income in 1919 as in 1914 and finds that a \$2000 income has shrunk in purchasing power to \$970. "This is the principal reason for the decline of the gold production of the United States from \$101,000,000 in 1915 to less than \$50,000,000 this year," said Mr. McFadden.

The U. S. Mint sold for industrial consumption during 1919 nearly \$22,000,000 more gold than was produced from the mines of the United States, while this year the drain on the monetary gold stock will probably be \$40,000,000. The American Bankers Association passed a resolution on October 2, 1919, urging upon the Government the necessity for maintaining a domestic production of new gold in sufficient volume to satisfy the industrial requirements of the arts and trades. To comply with the specifications of this resolution, the soundness of which cannot be questioned, I introduced H. R. 13201 on March 22, 1920.

Since the industrial consumers of gold are the only ones in the country receiving raw material at the pre-war price, while the general increase in all commodities was 112% in 1919 as compared with 1914, it is evident that they are being heavily subsidized. Mr. McFadden

emphasizes that the imposition of this excise tax merely adjusts the cost and price equation between the producer of new gold and the consumer of gold in the industrial arts, and is free from all monetary entanglements. A free gold market is maintained under the provisions of this bill for the reason that the excise tax is collected on the finished product as sold, and not upon the bullion which is sold to the manufacturers. There is nothing in the bill which in any way alters the number of grains in the standard dollar, the unit of our monetary system. The bill creates the governmental machinery by which the consumer of gold in the industrial arts may pay more nearly the cost of production for his raw material. The stimulus to the gold producer specified in this bill is equal to the excise tax imposed, and is no greater than the exchange premium paid by Great Britain in the latter part of 1919 to the South African producer, whose operating conditions are more favorable than those in the United States.

In addition to paying the exchange discount, which in the case of the French industrial consumer of gold would amount to 100% more in francs than the price paid before the War, the French government has imposed a sumptuary tax for the use of gold in the fabrication of articles (other than money) of 60 francs per hectogram (\$3.73 per fine ounce) by law of June 25, 1920. Previous to that date the guarantee tax was 37½ francs per hectogram. The French government justifies this tax in a formal document transmitted by the U. S. Bureau of Foreign and Domestic Commerce, as follows: "Moreover this tax, striking as it does luxury goods, or unessential articles, enters into the category of a sumptuary tax, the levying of which is admitted by all economists as a legitimate procedure."

It is important that the gold-mining industry be kept alive for fear that with greatly reduced production there will be difficulty in retaining the gold standard during a popular campaign for credit restriction accompanied by declining prices. The continued depletion of the gold stock by excess exportation and industrial use will seriously impair the public confidence in the Nation's finance and currency unless a normal gold output is insured.

The gold-mining industry will be completely shut-down unless constructive aid is provided without delay, in which event it will take years to develop a normal output of gold at a very much greater expense. To allow the gold mines of the United States to cave in and fill with water entails a waste of developed gold resources, which in a most critical hour of financial need will cause want. No argument can be made in favor of waste. The time to act is now before the industry is shut-down.

MISFIRES should not be approached even for the purpose of inspection until three hours have elapsed, if fuse was used, and ten minutes, if electric detonators or electric igniters were used. These are minimum recommendations. It would be preferable to allow a longer time, for fuses have been known to hang fire as long as twelve hours.

*Issued by Mr. McFadden himself.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

HIGH-GRADE ORE FOUND IN THE LOST DUTCHMAN.

PATAGONIA DISTRICT.—The Three-R mine is reported to be diamond-drilling with excellent results. R. R. Richardson has a large force of men also at work in Josephine canyon 18 miles north-west of Patagonia. It is said that the McDonald mine in the Santa Ritas is working a full force on the 300-ft. level, cross-cutting north to intersect a vein under the old workings.

GLOBE-MIAMI DISTRICT.—It is reported that the Inspiration-Needles property has been sold to the British Inspiration Copper Co. News has just been received in Globe that ore assaying in the neighborhood of \$408 per ton has been found in the old and famous Lost Dutchman mine, situated near Fish Creek hill, on the road between Phoenix and Roosevelt. The assay is said to have been taken from the face of a drift on the 100-ft. level, and was not picked ore in any sense. The Lost Dutchman mine, approximately forty years ago was the property of Jacob Wolz. Prospecting for its re-discovery has been carried on since 1913, and the present property located.

HILLSIDE.—The Lawrence group of mines in the Eureka district is reported to have been taken over by W. J. Mayer and C. E. Barton, from C. C. Stukey of Prescott. Development, it is said, will be undertaken by a new corporation, known as the Bagdad-Hillside Mining & Development Co.

MAYER.—The Arizona-Binghamton is reported to be milling 200 tons per day, with a monthly production of 300,000 lb. of copper. The Shannon Copper Co. will shortly resume operations on its Yeager Canyon property. Reports are current that production has commenced at the Gillespie property of the Arizona Copper & Mining Corporation and a twenty-ton mill will be erected to handle a developed ore-reserve of approximately 20,000 tons.

JEROME.—Mining conditions around Prescott and Jerome are reported as steadily improving. The present stable condition of the silver market is creating a feeling of confidence, and many of the old silver mines have been re-opened and new ones located. The Verde Central Copper Co. reports excellent showing in the face of the tunnel. Jack Hooper, formerly in charge of the Gadsden property of the Calumet & Arizona Mining Co., is now in charge of operations at the Zonia mine, near Kirkland. Two shafts are being sunk on this property and indications are promising.

KINGMAN.—The Gold Ore is reported to have struck a four-foot vein sampling about \$40 per ton in its east drift. Ore also is said to have been struck in the west drift.

PARKER.—Announcement is made that development will be resumed at the property of the Arizona Standard Copper Co., 14 miles east of Parker. It is reported that a leaching-plant and a four-unit ball-mill will be installed at once. Each unit will be capable of milling 125 tons of ore per day and the company expects to be operating within four months.

GLOBE.—The Iron Cap Copper Co. has recently filed suit in the Superior Court against the Arizona Commercial Mining Co. to prove apex rights. The first action in this matter was filed in the courts of Massachusetts, those courts having denied jurisdiction, the company took it into the equity court of the State of Maine. The suit filed here on October 5 is expected to finally settle the litigation and will probably be tried in the near future.

PEARCE.—George Brown, general manager for the Midlemarch properties has reported that 20 men are employed developing more water for the mill. The shaft has been sunk 130 ft. deeper and drifting is in progress. Recent differential-flotation tests on the copper-zinc ore are reported as successful and operations will commence as soon as sufficient water is developed.

OATMAN.—Judge Bollinger has not yet recovered from injuries received in the wreck of Governor Cox's special, and the case of the Tom Reed Mines Co. against the United Eastern Mining Co. has therefore been postponed from October 4 to November 8.

MICHIGAN

THE COPPER MARKET VERY DULL BUT OPTIMISTIC FOR THE FUTURE.

CALUMET.—Metal shipments from the Lake have been negligible for the past several weeks and the copper is piling up on the docks, awaiting a turn in the price. Even domestic business seems to be at a standstill and industries that formerly consumed large quantities of copper are entirely out of the market. Notwithstanding this stagnation, production holds well to the normal of the past six months. In fact, most of the companies report an increase in their organizations. This will make for greater production, even though there is no more demand for metal than at present. The belief here is that the worst has been experienced in spite of the fact that the

past week has brought about a slight drop in the price of the metal.

Arcadian Consolidated has resumed sinking in its New Baltic shaft and has gone about 15 ft. below the 600-ft. level. The south-east corner of the shaft is now in the lode. The cross-cut to the vein from the 600-ft. level on the south did not give quite as good a showing as was obtained on the opposite side where the copper content of the lode was exceptionally high. In the New Arcadian shaft, the richest openings are near the northern boundary or the Baltic line, while the lower levels revealed the best mineralization. It will be three or four months before Ahmeek's cross-cut through the Ahmeek fissure penetrates the Kearsarge conglomerate for the work is proceeding slowly. The tunnel is only 6 ft. square, permitting only limited mining operations. Cross-cuts on the fissure are boring toward the conglomerate from the 15th to the 22nd level and also on the 5th and 11th, so it is obvious that each opening will permit a thorough exploration of the Kearsarge. In fact, when Ahmeek completes its openings on the conglomerate it will be pretty definitely established whether the vein contains copper or is barren. Ahmeek's tonnage for September was the best since last winter. The rumor that Hancock Consolidated is to sell its holdings to Quincy has been officially denied. The fact that Hancock and Quincy are jointly installing a concrete reservoir or retaining wall on the 53rd level of Hancock gave rise to the rumor. Victoria is producing between 60 and 75 tons of copper per month. The company has a considerable stock of copper on hand and is selling only enough to meet current expenses. About 100 men are employed in sinking and drifting and the showing at the 28th level is reported by the management as very encouraging. The lode is yielding considerable mass copper as well as good stamp 'rock'. Victoria's cost is lower than the average for Lake Superior producers because both its mine and mill are operated by water-power.

NEVADA

RENO CHAMBER OF COMMERCE ESTABLISHES BUREAU OF MINING INFORMATION.

COPPER CANYON.—There has been developed in the mines of the Copper Canyon Mining Co., operating seven miles from Battle Mountain, 1,000,000 tons of ore with an average copper content of 2.40%, according to F. Sommer Schmidt, general manager. The company owns, or holds under option, a total of 3000 acres and a patented mill-site and water-rights. The greatest depth attained in the mines is 310 ft. and most of the ore is exposed, or partly so, through six shafts, the Copper Queen, Contention, Chase, Sweet Marie, Widow, and Empire, extending in a general direction, as named, south-east along the mineralized area. The orebody as now developed in the Sweet Marie is 600 ft. long and 87 ft. wide on the 120-ft. level, with an indicated thickness of 70 ft. This block is estimated to contain 417,600 tons of partly developed 2.58% ore. The orebody, as opened in the Chase on the 130 and 185-ft. levels and by raises from

these levels, contains 256,400 tons of partly developed 1.82% ore. The orebody has been developed in the Contention to a depth of 130 ft., above which it has been opened for a length of 300, a width of 100, and a thickness of 40 ft., giving an estimated 100,000 tons of 3% ore. The Copper Queen orebody at a depth of 120 ft. has been opened for a length of 120 ft., a width of 2½ ft., and a thickness of 50 ft., giving an estimated 1500 tons of 12¼% ore. The orebody has been opened on the 150-ft. level of the Widow by a 200-ft. drift, with raises driven, at 50-ft. intervals, 40 ft. to the gossan. The average content of the ore in the raises is 7% and in the drift 3%. The width has been narrow, but the ore is widening gradually, and at present the north face consists of a 20-ft. width of 4% material. Mr. Schmidt describes the formation in the district as consisting of limestone, clay stone, and quartzite, intruded by monzonite dikes. The ore-bearing sedimentaries dip east at 20 to 30° and they are cut by dikes of varying thickness.

GOLDFIELD.—From June 16, when the Development mill started, to about six weeks ago there was 41 carloads of ore of a gross value of \$22,000 shipped to the mill by Florence lessees. This gives a value per ton of about \$13, according to unofficial figures. The shippers were the Development, Hinds, Cracker Jack, and Boesch leases. The largest tonnage came from the Reilly block. Few shipments have been made in the last six weeks. The south-east cross-cut being driven by the company on the 358-ft. level has been advanced 1200 ft., according to E. A. Byler, engineer for the company, and the objective is nearly reached. No work has been done west of the shaft recently. The Development has bought the Gold Hill group of nine claims, 26 miles south of Goldfield, on which A. I. D'Arcy, manager for the Development, has furnished the following information: The vein, 14 to 60 ft. wide, is exposed on the surface for 2200 ft. There is 16,000 tons of \$8.50 ore partly blocked out, according to assays of 107 samples. The gold is found with limonite, and at one place in the lower tunnel sulphide ore is exposed. The vein is in an almost vertical fault-fissure, of which one side has been faulted down 200 ft. The walls consist of alternate layers of limestone and shale. The vein-filling is porous quartz and limonite, the gold being found in the latter. Cyanide-leaching tests of the ore, crushed to 10-mesh, gave an extraction of 94% of the gold in 72 hours.

RENO.—Development of the little-known minerals and metals is contemplated by the Reno chamber of commerce through a recently established bureau of mining information. The bureau purposes to bring together buyers of these minerals and owners of deposits. Owners have been invited to send in descriptions of their properties to the bureau and a file on inquiries and buyers is kept so valuable services can be rendered both parties.

CACTUS.—The Cactus Nevada Silver Mines Co. informs us that the statement in our issue of October 9 was incorrect, the fact being that the company has not laid off any miners and is amply financed through the firm of Fynney & Cutter. We are glad to make this correction.

UTAH

THE INTERSTATE COMMERCE COMMISSION TO INVESTIGATE
FREIGHT-RATES IN UTAH.

SALT LAKE CITY.—The shortage of railway cars is affecting the output of coal in Utah. During one week recently, the production was but 71% of normal. Of the other 29%, 23 was due to lack of cars, 5 to mine disability, and less than 1 to labor shortage. At this time of the year, production should average 120,000 tons per week, whereas recently it has been but 85,000 tons per week. One railway serving the coal mines supplied but 50% of the cars needed. The Interstate Commerce Commission has ordered an investigation of the action of the Utah Public Utilities Commission in refusing to permit increase in intrastate rates on coal and ore, similar to the advance in interstate rates. The hearing will begin in this city on November 1.

AMERICAN FORK CANYON.—John H. Wootton of the South Park Mining Co. has a force of men engaged in driving a tunnel opposite the Pacific mine. Mr. Wootton feels confident of finding the Pacific fissure. At the Belorophon property, the mill has been running steadily for several weeks. Fred Leonard, of Salt Lake City, has a surveying party at work at the Silver Bell property, preparatory to active operations. At the Pacific mine the company is accumulating a stock-pile of silver-lead ore of milling-grade, which will be treated when a sufficient quantity has accumulated.

GOLD HILL.—At the present time the Western Utah Copper Co. is shipping about 250 tons of low-grade fluxing ore daily. The company employs the 'finger raise' system of caving, the same as used in the Ruth mine of the Nevada Consolidated Copper Co. The orebody of this company is a replacement in marbelized limestone along a limestone-granodiorite contact. On the surface the ore-shoot is 300 ft. long and from 10 to 80 ft. wide. On the 300-ft. level, the ore-shoot is 150 ft. long and from 60 to 80 ft. wide.

EUREKA.—As a result of development in the Chief Consolidated mine, commercial ore has been found in the new zone at the easterly end of the company's holdings. Some months ago, small bunches of ore were encountered which were not of shipping-grade; these small stringers were followed with the result that the new orebody was discovered. Recently shaft No. 2 at this property reached the contact between the porphyry and limestone. Cecil Fitch, manager, says the shaft now has a depth of 1600 ft., and that it is expected the water-level will be reached by the end of the year. Mr. Fitch states the company is preparing for the annual assessment work on the unpatented claims. This work will include sinking two shafts, one being 4000 ft. north-east of the Central Standard workings, and the other at the extreme north end of the Chief's territory. Shipments from this district for the week ending October 2 totaled 131 cars, of which the Chief Consolidated shipped 30; Tintic Standard, 29; Mammoth, 23; Dragon, 10; Iron Blossom, 8; Eagle & Blue Bell, 8; Grand Central, 6; Iron King, 3; Gemini, 2;

Bullion Beck, 2; Swansea, 2; Centennial-Eureka, 2; Gold Chain, 1; Alaska, 1.

Figures recently published by V. C. Heikes of the U. S. Geological Survey show that the silver output of this district during 1919 was considerably over one-half of the output from the entire State; the production being 6,815,608 oz. for the Tintic district and 11,649,961 oz. for the State. The gold output of this district in 1919 was 25,900 oz.; lead, 24,842,544 lb.; copper, 2,254,848 lb.; and zinc, 93,571 pounds.

The shaft being sunk at the property of the **Pinion**

MAP SHOWING JEROME, ARIZONA, AND BRANCH ROADS
CONNECTING IT TO THE MAIN LINES

Queen Mining Co. has reached a depth of over 800 ft. The rock now being taken from the bottom of the shaft contains some silver and resembles the formation which lies just above the big ore deposits in the Tintic Standard. The East Warm Creek Irrigation & Canal Co. has filed suit in the District Court of Utah county against the Tintic Standard. The plaintiff asks that the defendant be enjoined from the use of the waters of Warm springs and Warm creek, situated about three miles east of Goshen, near the site of the mining company's new concentrator.

BIG COTTONWOOD CANYON.—At the property of the Howell Mining Co. development work is being pushed steadily. A deep tunnel was started to gain 325 ft. of depth. Recently this tunnel encountered a fissure in the quartzite in which a seam of galena occurs. It is not believed that the present find is connected with the deposits in the upper workings, but a survey is being made to determine the question. The Tar Baby Mining Co. is steadily developing on property adjoining the Cardiff. Some time ago the Tar Baby company drove an upper tunnel, which was all in quartzite and a raise through the quartzite encountered shale, as did a similar raise in the Cardiff property. The lower tunnel was driven in limestone, from which an incline raise has been made. This raise is 30 ft. vertically above the tunnel floor and is in a brecciated limestone with considerable mineralization. At the Cardiff mine, production is being maintained at 65 or 70 tons per day, averaging \$50 per ton. This ore is being mined from the 600-ft. level workings, and from the 800 and 900-ft. level workings, which were recently unwatered.

PARK CITY.—Ore shipments from this district for the week ending October 2 totaled 2153 tons, of which the Ontario shipped 704; Silver King Coalition, 544; Judge M. & S., 422; Daly-West, 230; Naildriver, 180; and Keystone, 60.

ALTA.—An assessment of 1c. per share has been levied by the Woodlawn Copper Co. on all outstanding stock. The assessment is delinquent November 16 and the sale date will be November 30.

WASHINGTON COUNTY.—The right of escrow expiring on June 1, 1921, held on the property of the Silver Reef Consolidated Mines Co., was taken up on September 30 by the McQuatters Corporation of New York. The property is about 20 miles from St. George, and the ore deposition is unique in that it is in sandstone. According to the U. S. Geological Survey, the value in the ore in the upper workings is practically all in cerargyrite, or hornsilver. Some parts of the vein contain copper carbonates in small amounts. The finding of a yellow uranium-vanadium mineral resembling carnotite, has been reported. In the shaft, about 250 ft. deep, officials report that sulphides have not been found. The ore occurs in beds from 2 to 17 ft. thick, and can be economically mined and transported to the mill. Ore was first discovered at this property in 1875, and by 1880, it is stated that the value of the output was \$3,243,740. Operations ceased in 1897 and were resumed in 1902. In 1909 the property was closed down and has remained idle until last summer, when the present owners resumed operations. Estimates vary as to the value of the production to date, although V. C. Heikes of the Geological Survey gives the output to the close of 1909 at 7,211,463 oz., valued at \$7,987,112. The tailing dump on the property is estimated to contain 150,000 tons, averaging about 6 oz. in silver per ton. Officials of the new company are Frank C. Morehouse, of New York and Salt Lake City, president; A. J. McQuatters, of New York, vice-president; Richard F. Parker, of New York, secre-

tary-treasurer; Alex Coldbath, of Salt Lake City, general manager. It is stated that a milling-plant will be constructed in the near future. According to engineers' reports, there is developed approximately two million tons of ore, which will average 10 oz. silver and 1% copper per ton.

BRITISH COLUMBIA

THE CONSOLIDATED M. & S. CO. ASKS FOR A HIGH TARIFF ON METAL IMPORTS.

PRINCETON.—The West Kootenay Power & Light Co.'s high-power line from Bonnington Falls, by way of Greenwood to Copper Mountain, has been completed, tested and proved satisfactory, and the power is now connected, so in all probability the Canada Copper Corporation will start operations at Copper Mountain and at Allenby shortly. The line is 190 miles long, and is believed to be the longest transmission in western Canada; it has a capacity of 110,000 volts, but until more power is required will be operated at 60,000 volts.

INVERMERE.—An interesting piece of blasting was done recently at the Bunyan mine, under supervision of E. J. Fader, general manager for the Silver Ores, Inc., which owns the property. The mine is situated on a hill-side, about five miles from here; the orebody being in places more than 100 ft. It was decided to change the mode of operating it from underground working to open-cut, or quarry work. With this end in view a cross-cut was driven for 60 ft., a drift run 20 ft., at the end of which a 20-ft. shaft was sunk. The shaft and drift were charged with 60% dynamite, well tamped, and exploded. The blast was a complete success, and an immense body of ore broken, estimated at between five and ten thousand tons. When this has been removed it will form a starting place for quarrying operations.

ATLIN.—The question of the ownership of the Engineer group of mineral claims, Atlin district, will be brought before the courts for decision. The property is valued at more than \$1,000,000.

STEWART.—The policy of the Provincial government in grub-staking returned soldiers has not been without result in the Portland Canal area. In the vicinity of Tide Lake, about twelve miles from Long Lake, such parties have uncovered a number of narrow high-grade veins of silver-bearing minerals, some of the samples from which assayed as high as \$700 per ton. George Clothier, government mining engineer, has recently returned from an inspection of the Bear River region, which suffered most from the heavy rains last summer.

PRINCE RUPERT.—The Graham Island Oil Development Co. has been organized for the exploration of lands believed to be oil-bearing, situated on Graham island of the Queen Charlotte group. The company claims to have four sections, staked before the War, comprising 2560 acres.

HAZELTON.—A contract has been awarded for the continuance of the tunnel of the Cascade group on mineral claims on Hudson Bay mountain for an additional 100 feet.

One of the properties inspected by John D. Galloway, resident mining engineer, is the mica property owned by the Mica Syndicate of Tete Juane Cache and Calgary, the holdings of which are situated on Mica mountain in Eastern British Columbia. There are five claims. Some adjoining crown-granted claims are owned by New York interests. Work was started by S. E. Beveridge, in May of this year. The dominating rock of Mica mountain is described as a coarse-grained garnetiferous mica-schist. The schists are intruded by granite varying from normal granodiorite to pegmatite and these pegmatite dikes contain the mica which is of the muscovite variety. There are crystals or 'books' ranging from 4 by 4 in. to 12 by 12, and still larger are found.

TRAIL.—The attitude of the management of the Con-

culty in competing with foreign countries.

Mr. Warren said that the industries were overburdened with taxes. The Province took 10% of their gross income, less certain deductions which did not include depreciation of mine property or take into account money borrowed by the company outside the Province. The company had paid in 1919 \$150,000 in taxes, over 16% of its net income. Half a million of the 10% dividends had been taken from reserve funds.

During the last nine days of the month of September, 12,744 tons of ore and concentrate was received at the smelter, bringing the total for the first nine months of this year to 257,774 tons. The Consolidated company's mines provided 11,549 tons of the shipment, the other contributors being: Emerald, Salmo, 33 tons; Florence,

HOLLINGER CONSOLIDATED GOLD MINES, LTD., ONTARIO

solidated Mining & Smelting Co. with respect to protection against metal imports has been presented to the Canadian Tariff Commission. J. J. Warren, president of the company, complained of the removal of the 7½% war-tax, asserting that, in the confident belief that this impost would remain in force, the company had made investments of a substantial character. Over \$250,000 had been expended in developing fluor spar deposits and commitments of equal amount had been assumed in the construction of a rod-mill and other additions to the plant at Trail.

The company's output in lead was 100 tons, about equal to the Canadian consumption. Until 1919 the Canadian tariff was the normal 15% plus the 7½% war-tax as against a United States rate of 25%. Last year the whole was removed and a specific duty of 1c. per pound imposed. The lead producer in this country is seriously menaced by lead produced in Spain, offered here as a British product. The United States has protection of 2c. per pound and notwithstanding was faced with competition from Mexico, Germany, and Spain via England. The exchange situation presented another diffi-

Princess Creek, 95; Iron Mask, Kamloops, 45; Josie, Rossland, 448; Monarch, Field, 78; North Star, Kimberley, 224; Paradise, Athalmer, 57; Providence, Greenwood, 47; Queen Bess, Alamo, 40; Sally, Beaverdell, 37; Twin, Princess Creek, 26; Velvet, Rossland, 28; and Washington, Sandon, 37.

The Trail board of trade submitted to the Commission a memorandum emphasizing the importance of adequate protection to the Trail smelting industry. While there were only between 2000 and 2500 men actually employed at the smelter it was argued that at least 20,000 people were dependent on the successful operation of the plant.

SILVERTON.—The statement of the Standard Silver-Lead Mining Co., operating the Standard mine, near Silverton, Slocan district, shows a cash surplus of \$367,996 on July 31 last as compared with \$341,825 on March 31, 1920, and \$298,010 on December 31, 1919. Profit for June of this year was \$10,952.

VICTORIA.—Among the recently incorporated British Columbian companies is the Lowox Steel Co., with an authorized capital of \$500,000 and head offices in Victoria. Its business is described as steel makers, colliery

owners, and operators and along other lines of the iron and steel manufacturing industry. Returned soldier prospecting-parties, grub-staked by the Government, have recorded promising copper prospects on Mount Diadem, near Jervis inlet, lower mainland of British Columbia.

ONTARIO

COBALT AN IMPORTANT ITEM IN ONTARIO ORES.

PORCUPINE.—Shortage of labor continues to curtail the output of the mines. Although large numbers of laborers are returning only a small proportion of them go to the mining camps; mine managers, however, expect that before winter sets in they will be able to obtain all the labor they require. The Hollinger Consolidated and the Dome Mines, after having each purchased a carload of the low-grade cyanide for the purpose of testing it, continue to use the imported high-grade cyanide.

KIRKLAND LAKE.—The Lake Shore during August treated 1281 tons of ore with a recovery of \$35,261, the falling off in tonnage being due to the breaking of a ball-mill clutch and the re-lining of the mill. Production has now passed the million-dollar mark, the total to the end of August being \$1,011,579. Station timbering has been completed at the 400-ft. level and good progress is being made with the sinking of the shaft to a depth of 800 ft.

Surface exploration on the Granby-Kirkland has been completed and actual mining operations begun. A shaft is being put down on vein No. 4, one of the most highly mineralized of a series of eight veins. It is over 4½ ft. wide and gives encouraging assays. A mining plant will shortly be installed.

COBALT.—Three narrow high-grade veins have been opened on the surface at the Kerr Lake mine. They range in width from one to two inches and contain from 2000 to 6000 oz. silver per ton. The first vein was discovered while excavating for the foundation of a crusher, the second was found while extending the excavations so as to provide clearance for a conveyor, and the third was found while preparing a foundation for the motor which is to drive the crusher and conveyor. The veins occur within eight feet of each other, and are in the conglomerate which is 100 ft. thick at this point. The find ranks among the most important surface developments in recent years in Cobalt.

Following the discovery of high-grade ore at the surface of the Kerr Lake mine, the Crown Reserve has placed two machines on an upper level cross-cutting the line of strike of the veins which are about 90 ft. from the Crown Reserve boundary and which run south-east into Kerr Lake by north-west toward the Crown Reserve.

Nearly five tons of high-grade ore has been taken out by open-cut work on veins of the Cane Silver Mines, in Cane township, in the Elk Lake district. The ore will average more than 500 oz. per ton.

The Nipissing Mines Co. has purchased the iron property of the Magnetite Mines Co. situated about 60 miles from New York, with ore-reserves estimated at many millions of tons. The price of the property and the cost of erecting a plant will, it is understood, entail an outlay of

over \$1,000,000. The ore is stated to run about 37% iron. Peterson Lake is again coming to the front as a producer, shipping about 20 tons of ore daily in addition to the re-treatment of its tailing at the Dominion Reduction mill, which yields a fair profit. An extensive underground exploration program is being carried out. With the increase in the price of cobalt metal to \$6. per pound (from \$3 to \$4 in the rough state) its recovery as a by-product of the silver mines becomes an important source of revenue. The cobalt content of shipments from the mines if over 4% is paid for at the rate of 2 to 4 cents per unit according to the grade of the ore. For instance, shipments comprising 5% cobalt metal are paid for at the rate of 10c. per pound, and the higher-grade cobalt of 10% is paid for at the rate of 20c. per pound. The smelters at Thorold and Deloro are equipped for its recovery, which adds materially to their revenue. The rise in cobalt is stimulating interest in the South Lorrain district where the veins carry a large amount of this metal.

YUKON

GOLD PRODUCTION SMALL OWING TO THE DRY SEASON.

DAWSON.—The last boat of the season left this city for Fairbanks on September 26, which is a sign that the season is rapidly drawing to a close. On the whole it has been disappointing. The gold output will be markedly less than that of last year; the reason for which is the unusual dryness of the past summer, and consequent lack of water for washing the ground that has been mined. At many properties there are large dumps of earth that have been mined, but will have to remain until next year before they can be washed. Consequently next year's output will have the credit for much of this season's work. An important gold strike has been reported from Chandalar, near Fort Yukon, which the early enthusiasts describe as being likely to rival the Klondike. Such reports are not infrequent, and until further details are obtained no idea of the value of the new strike can be given. A number of claims have been staked and a trail is under construction. A wireless plant is being erected at Fortymile. O. B. Perry, manager for the Yukon Gold Mining Co., before leaving for the south, said that his company intended to carry out development work at Mayo and install machinery that would mean a capital investment of half a million dollars. Ore is being moved by tractors from the company's mines to Mayo Landing, and it is expected that it will be transported to seaboard before the winter stops navigation. The Yukon Silver Mining Co. has decided to erect a concentrating-plant at Keno Hill, and the heavy machinery for it will be hauled in over the snow this winter. The Fortymile Power & Dredging Co. has done a large amount of drifting on Dennison fork, but has not had sufficient water to wash the ground. The company is doing a lot of exploration, which will be continued through the winter, and it expects to have enough ground for one or two dredges blocked out by next spring. E. P. Burrall, of the Canadian Klondyke company, states that his company has enough ground to keep it busy for the next decade.

THE MINING SUMMARY

CALIFORNIA

Amador County.—The best ore found in the Old Eureka mine since its acquisition by the present owners is reported on the 3500-ft. level of the property. A large vein of milling-ore has been opened on the 3050-ft. level of the Plymouth Consolidated group at Plymouth, owned by the W. J. Loring syndicate.

Nevada County.—The commissioner of the General Land Office has granted the application of the Golden Center of Grass Valley Mining Co. for the Roche Rock claim located by it within the townsite limits. Good progress is being made in re-opening the Red Ledge mine in the Washington district, according to Lewis Hind, who was here recently. A big shoot of milling-ore has been cut in the lower tunnel and is being developed. Starting up the new mill at the Grass Valley Boundary mine has been delayed a few days by the decision to install a concentrator purchased from the Champion plant near Nevada City before beginning operations.

Litigation involving the Black Bear mine will end in November, and soon thereafter steps will be taken to re-open the property. This is the announcement of William Bucholtz, the principal owner, who has just returned from Oklahoma. Bucholtz, as general manager, brought suit to recover money advanced by him and for salary, and it is expected the title will be confirmed to him within a short time.

Plumas County.—Representatives of the Guggenheim company were in Johnsville last week negotiating for the purchase of the Plumas Eureka mine. This mine was located in 1850 and sold in 1871 to the Sierra Buttes Co. of London. It was closed down in 1897. In 1909 it was bought by the Plumas Eureka Mining Co. The property, which is situated on the east slope of Eureka peak, is 2500 acres in area and includes timber rights. The mine is not being worked at present.

Shasta County.—The United States Smelting, Mining & Refining Co., owner of the Mammoth mine and smelter, has bought the Holt & Gregg Co.'s lime quarry, lime kilns, electric railroad from works to quarry, and all buildings in Kennett for \$20,000 according to the revenue stamps on the deed. An electric railroad 2½ miles long connects the lime quarry with the smelter. The purchase of the property is taken to indicate an early resumption of smelter operations.

The Shasta Exploration Co. is contesting the issuance of patents to the United States Smelting, Refining & Mining Co. (Mammoth Copper Co.) for the Wren, Crow, Coon, Last Chance, and Comstock mining claims in the Backbone district near Kennett. The Shasta Exploration Co. holds that all or a portion of these claims conflict with the boundaries of its Eva Lode, Carrie Alice, Vernie, Diamond Fraction, and Six Point mines. The action will be tried in the Superior Court before patents can be issued to either company.

Sierra County.—Five hundred pounds of specimen gold ore has been taken from the Tightner mine during the last few days. This is according to the report reaching here. The Tightner, at Alleghany, has long been noted for its rich pockets. It is stated that the discovery was made in a tunnel at a point only 18 ft. from where work was abandoned by the former operators. The property was taken under bond by a company of mining men several months ago and Fred Searles is in charge as superintendent.

COLORADO

Breckenridge.—Mines and dredges in this district are operating short handed. High-grade silver ore is coming from the Gold Bond on Mount Guyot, operated under lease. The Horn mine in the same section, long idle, has been opened. The Brooks-Snyder Schock Hill is again producing high-grade ore; 14 sacks mined by lessee Ange contained 168 oz. gold per ton. The Morgan lease is shipping silver ore of \$45 to \$70 grade from the same mine. Wellington Mines paid its 19th dividend, amounting to \$100,000, early in the month.

Cripple Creek.—The Portland Gold Mining Co. will pay the regular quarterly dividend of 1¼c. per share, amounting to \$45,000 on October 20 to stockholders of record of October 12. Lessees of the United Gold Mines Co., on the Hardwood claim of the Damon group, Ironclad hill, continue production of high-grade ore.

Denver.—Manganese ore from California, Montana, Nevada, and old Mexico is being received by the Ferro Alloy

WINTER HOOD ON STACKER OF YUKON DREDGE AT
MURRAY, IDAHO

company of this city and ferro-manganese is being manufactured to the extent of 200 tons monthly.

Georgetown.—Lessees on the Waldorf are mining and shipping smelting-grade ore. Last week's shipment brought \$75 per ton. The Backbone lessees are shipping milling-grade ore to the Wasatch mill and Mount Helen mine lessees are also shipping milling-ore. The force at the Georgetown tunnel has been increased and a good grade of ore is being sent to the concentrator.

Leadville.—Austrian lessees on the Little Jonny continue shipping high-grade from the Brece Hill mine, and are now drifting into virgin ground. The estimated value of the ore shipped to date by lessees exceeds \$300,000. Operations have been resumed on the Tucson claim of the Iron Silver Mining Company.

Silverton.—The Hanson Peak Mining Co. has acquired the Independence and Malone claims formerly owned by the Finney Jones estate. The property adjoins the Sunnyside mine, and Pete Holmgren, the manager, is mining ore averaging \$40 per ton. Eastern interests, with G. H. Bibb

in charge, have taken over the Eastern Star. Equipment and supplies have been sent in for operation during the winter.

Telluride.—Shipments of concentrate during September were 33 cars from the Smuggler and 31 from the Tomboy. The Liberty Bell mill shipped 4 cars.

IDAHO

The Carbonate Mining Co. plans to start development work in the near future. The company owns a group of claims near Beeler in the Pine Creek district of the Coeur d'Alene. The Jim Blaine and Bristol properties in the Pine Creek district tributary to Kellogg have been merged into the Jim Blaine Silver syndicate. The Jim Blaine property is located a half-mile from the main works of the creek. Surveys for the new tunnel which is to be driven from the creek level to cut the Bristol and Jim Blaine veins have been completed. Contracts for 400 ft. of additional work in the cross-cut on the Slavonian Mining Co.'s property in Wardner have been let. The cross-cut is now 900 ft. long and is expected to reach the vein at 1200 ft., leaving 300 ft. yet to run. The present contract calls for a drift on the vein, should it be reached before the 400 ft. is completed. The Nabob mine on Pine creek, in the Coeur d'Alene, will join the regular shippers according to reports. The raise connecting the lower and upper workings has been completed and other details worked out for the economical handling of ore from the mine to the mill. All the ore-bins at the mill are full of ore and ore is broken in four stopes in the mine, ready for movement to the mill. A station has been cut at the top of the raise and a hoist installed. A crew of 60 to 75 men will be employed underground and in the concentrator. Plans for constructing a 100-ton mill for the Jack Waite property near Wallace have been made and ore is being transported by two motor-trucks from the mine to Prichard, a distance of 13 miles. Shipments are averaging 55% lead.

NEW MEXICO

Pinos Altos.—The shaft-house of the United States Copper Co. near here was destroyed by fire during the past week. The origin of the fire is unknown. The contents of the office, which was in the building, were destroyed, something that will naturally cause a great deal of inconvenience as well as loss, but it is believed that the machinery in the building was not seriously injured. Several new claims have been located in the south-eastern part of the district and assessment work is being done, preparatory to further development. One of these properties known as the Clint is an old-time producer, but on account of the low price of silver was abandoned several years ago. A new shaft is being sunk, and the old shaft re-timbered so that operations may be carried on through both shafts.

Silver City.—The New Mexico Mining Association met Monday afternoon, October 4, for the purpose of perfecting their organization as the New Mexico Chapter of the American Mining Congress. John M. Sully, manager for the Chino Copper Co., acted as chairman of the meeting. About seventy operators and mining men from all over the State assembled and held an enthusiastic meeting.

White Signal.—Development work on the radium-bearing ore deposits at White Signal has been discontinued. It is understood that the trouble is due to the difficulty of perfecting a system of separation of the metals from the torbernite ores, which are said to differ considerably from any being used for the production of commercial radium at this time. The Radium Co. of Colorado, which was interested in the deposits, has had an expert on the ground for several weeks. During the progress of the development work the mineral was found at a number of different points; most of the work, however, was done through the Merry Widow shaft, which had been sunk to considerably over 200 ft.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Henry Krumb is at Superior, Arizona.

J. B. Tyrrell writes from Newfoundland.

A. W. Allen has left Peru on his way to London.

L. A. Butler left New York last week for West Africa.

Albert Turner has left London to go to Oatman, Arizona.

C. M. Weld has removed his offices to 2 Rector street, New York.

Howard D. Smith was in San Francisco last week; he is now at Ely, Nevada.

Horace G. Nichols was here last week on his way from Mexico to British Columbia.

W. Fellow-Harvey has left Vancouver on his return to London by way of New York.

John E. Bergh, of the firm of Sturtevant & Bergh, of Salt Lake City, is at Tobar, Nevada.

Ralph J. Baverstock, of Baverstock & Payne, Los Angeles, has been to Calexico, Lower California.

H. Vincent Wallace, of Los Angeles, passed through San Francisco on his way to Eureka, Nevada.

L. V. Waterhouse has been appointed general manager for the Mount Hope company, in New South Wales.

E. T. McCarthy has arrived here on his way from London to China. He sails from Vancouver on October 21.

R. C. Gemmell and **D. D. Moffat** are making a tour of inspection of the Ray Consolidated and Chino Copper mines.

Frederic R. Weekes has returned to New York from the Portland Canal and Alice Arm districts, British Columbia.

Solon Spiro, president of the Silver King Con. M. Co., at Park City, Utah, has returned to Salt Lake City from New York.

Y. Fukihara, of the Mitsubishi Mining Co., Tokio, Japan, was in San Francisco last week and has gone to Tonopah, Nevada.

James K. Dickson, recently mining engineer to the Honduras Rosario Mining Co., in Honduras, has arrived in San Francisco.

H. S. Weigall has been transferred from the Seoul Mining Co., in Korea, to become general manager for the Taio Gold Mining Co., at Fukuoka-ken, in Japan.

A. J. Reef, who has been associated with the Salt Lake City office of the United States Smelting Co., has been transferred to the Boston office of the company.

Craig Sandusky, superintendent for the Zuma Mining Co. at Eureka, Utah, has resigned and will go to Colorado. **A. C. Nebeker**, of Milford, Utah, will succeed him at the Zuma.

W. M. Thayer, formerly professor of geology at the Ohio Mechanics Institute, has resigned to devote himself to consulting practice in oil and mining geology at Cincinnati, Ohio.

R. E. McDonnell, of the firm of Burns & McDonnell Engineering Co., Kansas City, was elected president of the Northwest Waterworks Association, at the ninth annual convention, in New Orleans, on September 24.

D. C. Jackling left San Francisco on October 1. He visited the Butte & Superior and the Mesabi iron properties, and is now at Hayden, Arizona, inspecting the Ray Consolidated property. After a short visit to the Chino property in New Mexico, he will go to New York.

David A. Herron, manager for the Tomboy Gold Mines Co., at Telluride, Colorado, died at Denver on September 24. He was about to resign on account of ill health; nevertheless the sad news comes as a shock to his many friends.

THE METAL MARKET

METAL PRICES

San Francisco, October 11

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	18.75
Lead, pig, cents per pound.....	8.00-9.00
Platinum, pure, per ounce.....	\$105
Platinum, 10% iridium, per ounce.....	\$145
Quicksilver, per flask of 75 lb.....	\$75
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-13.00

EASTERN METAL MARKET

(By wire from New York)

October 11.—Copper is stagnant and lower. Lead is quiet and easy. Zinc is inactive but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

METAL MINING IN SEPTEMBER

Stagnation in metal mining is reported by the Federal Reserve Board. Because of the low purchasing power of the metal, the gold output in California and Nevada continues to decline. Silver mines in Utah and Idaho, however, are working on a basis which will probably be slightly ahead of 1919. Copper production in Arizona will probably exceed that of 1919, but elsewhere there is no change. The lead output of Utah and Idaho has been small, but some idle mines are resuming operation with prospects of production exceeding 1919. Recent freight-rate increases have produced discouragement, and greater costs of supplies may further lower production. Zinc and lead have shown improvement in volume shipped and price paid. In Missouri, Oklahoma, and Kansas, zinc-ore shipments increased 20% and lead 12% in August over July. Stocks, however, increased 2000 tons. Car shortage is a serious problem in ore shipments, while new freight-rates will increase the cost of slab zinc by \$4 per ton.

The Comptroller of the Treasury has ruled that the Director of the Mint may purchase Alaskan silver at \$1 per ounce under the Pittman law, as Alaska is a part of the United States within the meaning of the law. Silver produced in the Philippine Islands, however, cannot be purchased under the Act, the Islands not being a part of the United States within the meaning of the Act, as United States laws do not generally apply to the Philippines. During the past week the Director purchased 432,000 oz. of silver, a total to date of 17,342,371 ounces.

According to W. F. Bartholomew, of Tucker, Bartholomew & Co. and a director of Seneca and North Bate mining companies, the copper situation is not quite as bad as generally supposed. Surplus stocks have declined since the first of the year and the next 30 or 60 days should see a resumption of metal buying, in his opinion. He says: "There has been abnormal delay in the purchase of copper by reason of the credit situation and the general desire on the part of manufacturers to reduce inventories to the minimum and this situation has been more pronounced because of the absence of European buying. Now in the absence of buying and an increase of stocks, prices have naturally been affected, especially in the face of the recent re-sale of copper sold to Japan but not shipped. Copper has been sold recently as low as 17½ c. per pound."

"Copper was the first commodity to be liquidated and is now down to a price which causes mines to restrict rather than produce. Deliveries from the last large sale of copper are just being concluded and new buying will soon have to take place. Stocks of copper on January 1, 1920, were 733,000,000 lb. On September 1 total stocks in this country were 577,000,000, or 156,000,000 lb. reduction in stocks from January 1 figures. Total sales in September were about 60,000,000 lb. Now Europe is bare of copper and domestic consumers' stocks are at the minimum so that the producers have the copper, and I maintain that under these conditions a healthy buying movement is due and there is no just basis for pessimism. In fact, I look for a pronounced change in the copper-metal outlook during the next 30 or 60 days."

MONEY AND EXCHANGE

Foreign quotations on October 11 are as follows:

Sterling, dollars:	Cable	3.51
	Demand	3.51 3/4
Francs, cents:	Cable	6.77 1/2
	Demand	6.88 1/2
Lire, cents:	Demand	4.05
Marks, cents		1.59

Eastern Metal Market

New York, October 6.

All the markets are exceedingly inactive and in some the situation is not satisfactory or bright. The general nationwide tendency to lower prices is having its effect in the metal markets, which are all at low levels, in some cases down to cost of production.

Copper buying is almost nothing and prices are largely nominal.

The tin market is lower and very quiet.

Lead has again declined with imported metal the predominating influence.

The zinc market is unchanged and very dull.

Antimony is a little lower.

IRON AND STEEL

The iron and steel markets are but little changed since last week. Buying is light and the tone is easy. Some see a slight improvement. Pittsburgh prices are firm at last week's levels. In general, however, the tendency is downward, but gradually so. Pig-iron is lower, with foundry even down \$3 to \$47. The key to the iron situation is the price of coke, which is still very high. Makers cannot be shown how pig-iron can come down with coke still very stiff. Production of coke is steady. There is a belief that the steel market will soon enter a more competitive condition with independents' prices nearer or close to those of the Steel Corporation. Billets have declined to \$50, as compared with a recent level at \$60. The sheet-bar market is off to \$65 to \$70. The steel-plate market is softening. All these refer to the outside or independent market.

The September pig-iron output was 3,129,323 tons, or 104,310 tons per day compared with 3,147,402 tons in the 31 days of August, or 101,529 tons per day. The September rate was the highest since February 1919, excepting March of this year. October is likely to exceed September in production. Eighteen furnaces were blown in during September and 10 were shut-down; the estimated capacity of the 319 furnaces active on October 1 was 106,220 tons per day, against 104,265 tons per day for 311 furnaces one month previous.

ANTIMONY

The market is extremely quiet and lower with wholesale lots for early delivery quoted at 7c., New York, duty paid. Jobbing lots are quoted at 7.25c.

ALUMINUM

There is a wider divergence between the outside market and the leading producers. Wholesale lots of virgin metal, 98 to 99% pure, for early delivery are quoted at 34.90c. f.o.b. producers' plant, by the leading interest, but at 28 to 29c. per pound, New York, by other sellers, handling largely foreign metal.

COPPER

There is no improvement in the situation. Consumers are still uninterested and buying is at low ebb. There has been no discernible change in the price situation, quotations being largely nominal in the absence of transactions in any volume. Most of the leading producers still adhere to a quotation of 18.75c., New York, for both Lake and electrolytic copper for October delivery, but are doing little if any business. There is strong talk of further curtailment of production. Costs are higher and prices weaker and it is argued that it is better business to leave the metal in the ground. The outside market is quotable around 18.50c., New York, as an average, though there may be small lots available at less than this. The British market was lower early last week but strengthened with more favorable strike news.

LEAD

The feature of the market was another reduction on September 29 of 1c. per pound by the American Smelting & Refining Co. This makes the third reduction since September 13, the total amounting to 1 1/2c. per pound. The new quotation is 7.50c., St. Louis, or 7.75c., New York. The outside market remains unchanged in conditions, being still ruled by the imported metal, which is offered at 7.50c., seaboard, for October delivery. In September the imports were 7630 tons, which is not heavy, relative to consumption, but which is influential under present market conditions. Demand is light, with buyers maintaining a waiting attitude, apparently expecting lower prices.

TIN

Up to the end of last week the market was almost at a standstill, although prices had settled to an attractive level. Consumers, however, were not interested and still show no interest. In fact some were offering to sell tin in isolated cases. There were really more sellers than buyers. Pessimism has even been apparent, but it is now believed by many that the worst is past. Early this week there has been a little more interest, largely by dealers who seem to be ready to pick up bargain lots, particularly for Eastern shipment. On Monday on the New York Metal Exchange 50 tons of October-November shipment was sold at 42.75c. and more could have been sold had there been sellers. Spot tin was reported offered at 42.50c., but not confirmed.

ZINC

The situation is materially unchanged. In the Eastern market imported metal is the dominant factor, while in the West the situation is characterized by lack of demand and lower output. Prime Western for October delivery in the East, based on imported metal, is quoted at 7.65c., New York, while the same grade at St. Louis is held at about 7.65c., or 8c., New York. There is very little buying except to cover consumers' immediate needs, either in the East or at St. Louis. Prices are therefore more or less nominal at 7.65c. for October delivery at New York or St. Louis.

ORES

Tungsten: Inactivity pervades the market. There has been some inquiry but no business is recorded. Consumers are apparently uninterested at least. Quotations are unchanged at \$4.50 per unit for some Chinese ore and high-grade foreign ores are held at \$5 to \$6 per unit.

Ferro-tungsten is unchanged at 80c. to \$1.05 per pound of contained tungsten.

Molybdenum: The market is entirely dead with quotations nominally unchanged at 65 to 75c. per pound of MoS₃ in regular concentrates.

Manganese: The general situation is unchanged. Consumers are well stocked and are not buying. There have been offerings of Indian and South American ores but no sales. Quotations are 60 to 65c. per unit, seaboard, but buyers are not interested above 55c. per unit. Imports in August are returned as 99,601 gross tons, or the heaviest of any month this year. The total to September 1 is now 334,590 tons, as compared with 249,810 tons to September 1, 1919.

Manganese-Iron Alloys: The market is still inactive with quotations for ferro-manganese unchanged at \$170, basis seaboard, for either foreign or domestic alloy and for spiegel-eisen at \$82.50, furnace, for the higher grade and \$80 for the lower. Some re-sale ferro-manganese is reported to have changed hands at \$160 to \$165. Imports of ferro-manganese in August were 9804 tons, the heaviest in any month this or last year.

Book Reviews

The Mining Laws of the British Empire and of Foreign Countries. Vol. I. Nigeria. By Gilbert Stone. 250 pp. Published for the Imperial Mineral Resources Bureau. For sale by the 'Mining and Scientific Press'. Price, \$4.

This is the first of a series of publications intended "to provide an up-to-date and authoritative exposition of the mining laws in force in different parts of the world, available both for the legal profession and for all those who are in any way interested in mining and minerals". The next volume will deal with the Gold Coast of West Africa and the third with the Transvaal. We welcome these publications in behalf of the mining profession.

Hydraulic Tables. By Gardner S. Williams and Allen Hazen. Third edition. Pp. 115, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The principal change as compared with the second edition of this book is the inclusion of the chapter on 'Additional Data', in which are discussed the results of the principal experiments on the flow of water that have been made in the 12 years since the appearance of the second edition. Various tables and other data on the flow of water through pipes and other passages, based on the Hazen-Williams formula comprise most of the book. There is also a division devoted to the flow of water over weirs. The book will be useful to the hydraulic engineer.

Steam-Shovel Mining. By Robert Marsh, Jr. Pp. 258, ill., index. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This book was apparently written for engineers and will be found particularly useful by all of that profession who are engaged on any work in which excavation of earth and rock plays an important part and it will prove equally useful for the manager and superintendent. Detailed descriptions of the different types are compared; modern methods of mining involving the use of power-excavators are described and there is much information covering the costs of operation. This, as everyone knows, is a particularly difficult task at the present but the author has tried to accomplish it by giving the unit factors at the time of writing and also under pre-war conditions. It is a valuable book.

Ten-Minute Talks With Workers. Pp. 208. Doubleday, Page & Co., New York. For sale by 'Mining and Scientific Press'. Price, \$1.

This is a series of 40 short articles from various issues of the Trade Supplement of the London 'Times', the wording being changed occasionally to suit American readers. Each article is a brief discussion of some subject connected with political economy, expressed in language suited to the man in the street and in the shop, but without any atmosphere of 'talking down' to the audience. In fact, the book might be called an anti-Bolshevik tract, and, as far as the reading matter is concerned, it is a good one. However, binding, printing, and other mechanical features are of such quality that the price is necessarily too high for a tract. The man that really needs to read the book will not pay the dollar for it, and employers and others can hardly afford to arrange for free distribution.

Practical Chemistry. By N. Henry Black and James Bryant Conant. Pp. 474, ill., index. The Macmillan Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

This book does not require the author's preface to tell one that it is intended as an elementary textbook for use in

the public schools. It is written in 'popular science' style and therefore will doubtless be interesting to many young people, a sugared pill of knowledge, but, for our own part, when we have wanted information from textbooks we preferred it, like cascara, 'straight'. The book aims to include industrial chemistry and chemical engineering in its field but the difficulty of covering this field is indicated by the illustration of 'A Stamping Mill' and the statement concerning the ore of the Lake Superior region that "In order to isolate 'native copper' it is necessary only to grind the rock to powder and then to heat it until the metal runs together and flows to the bottom of the mass".

Mine Bookkeeping. By Robert McGarraugh. Pp. 118, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.

It is a pleasure to see a book that, as the author states, has been prepared to supply a real need. It is intended for the engineers, superintendents, and operators of small mines. The present courses of instruction for engineers make little provision for education in business principles or in office routine and the average engineer is apt to take the returns from the office as gospel without appreciating the necessity of having all data properly collected and arranged, if trustworthy results are to be had, or to go to the other extreme and discard the office-prepared data and make up his own at a considerable loss of time, effort, and accuracy. Although the book is small and the author does not go into detail as much as is done in books intended for professional accountants, the technical man who lacks office experience and many others will find it useful.

Design of Highway Bridges. By Milo S. Ketchum. Second edition. Pp. 538, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

Changes in highway-bridge practice during the 12 years since the first edition of this book was published, particularly the increase of live loads and the growing use of reinforced concrete, have made necessary its revision and the almost complete re-writing of some parts. The scope of the book has also been extended so as to cover both concrete and timber bridges as well as steel. Part I discusses the calculation of stresses in the various bridge members. Part II covers the design of steel and of timber highway bridges, while Part III covers reinforced concrete bridges and foundations. In Part IV, various details of bridge design, contracts, estimates and costs, and bridge erection are considered. There are three appendixes, the first covering specifications for steel bridges, the second, specifications for concrete bridges, and the third contains various structural tables. The book will be indispensable to anyone engaged in the design or the construction of highway bridges.

Personnel Administration. By Ordway Tead and Henry C. Metcalf. Pp. 520, ill., index. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

The systematic study of industrial relations and the development of the technique of personnel management are so new that the literature of the subject is scanty, and much information is only to be found scattered through periodicals and official reports. The present volume is a fairly successful attempt to collect the most important of these data under one cover. That it is, in many places, too much colored by the authors' personal preferences regarding matters in dispute was, perhaps, unavoidable. Nevertheless, the book will be of value to the employer, the personnel manager, and to others interested in the subjects of which it treats. The scope of the book is best indicated by the section-headings, which are The Personnel Department; Em-

ployment Methods; Health and Safety; Education; Research; Rewards; Administrative Correlation; and Joint Relations (between employer and employee).

Brains in Overalls

OXWELD SERVICE ENGINEERS are ready at any time to apply up-to-the-minute oxwelding and cutting experience to your production problems wherever you are.

The Oxweld Service Engineer is no theorist—no experimenter—but a man of thorough technical education and wide practical experience. He embodies that happiest of combinations in industry—brains in overalls.

He will tell you how the oxwelding torch can benefit your business and he will make expert oxwelders and cutters of your own men.

There is no charge for this Service.

Write, wire or telephone to any of the addresses below and an Oxweld Service Engineer will go to your plant from the nearest of more than fifty centrally situated cities.

OXWELD ACETYLENE COMPANY
NEWARK, N. J. CHICAGO SAN FRANCISCO

WORLD'S LARGEST MAKER of EQUIPMENT for OXWELDING AND CUTTING METALS

T. A. RICKARD, . . . Editor

IN our issue of September 11 a note on 'Lead Production' was credited to the 'Metal Bulletin', whereas we learn now that only the statistics originated with that publication. The information, copied by us from a newspaper, originated with 'The Magazine of Wall Street' of August 21, 1920.

DOMESTIC exports of mining machinery during August, according to the Department of Commerce, amounted to \$1,071,845, of which \$463,623 was for oil exploitation and \$608,222 for other kinds of mining. Of the latter, Mexico took \$233,477 and was by far the largest buyer among foreign countries.

OXIDATION of a gold-bearing quartz vein at a depth of 2675 feet is announced from the Lonely Reef mine, in Rhodesia. This condition, it is said, is "connected with the existence of an extensive crushed zone through which the two levels immediately above have been passing". Do any of our readers know of a mine in which oxidation has been found to extend as deeply, or deeper?

BRAZIL is a great mining region; therefore the geology of the country is interesting to mining engineers. As a subject it has gained greatly in human interest by becoming associated with the life-work of John Casper Branner of Stanford University. We are glad therefore to publish an interesting letter in which our friend Mr. F. Lynwood Garrison reviews Dr. Branner's investigations as recorded on his geologic map of Brazil. Mr. Garrison incidentally gives us a good deal of information on the country, which, it will be remembered, can boast, among other things, the deepest mine in the world.

THE New Modderfontein, the greatest gold mine in the world, is doing well. It is on the Rand, in South Africa. We gave an account of its history and resources two years ago and concluded that it was the "greatest" gold mine by reason of its output, profit, and assured prospects. During the financial year ended on June 30 the total revenue of the New Modderfontein Gold Mining Co., Ltd., was £2,555,467. The working cost was £1,061,622 and the working profit £1,493,845. The average yield was 52s. 9d. per ton, which, at \$4 to the pound, is equivalent to \$10.50 per ton. The working cost was 21s. 11d., or about \$4.40 per ton. Dividends for the year amounted to £1,155,000, or 82½% on the capital. Since the com-

mencement of milling in May 1906 the mine has produced 8,681,480 tons of ore yielding 3,962,412 ounces of fine gold, from which £6,033,750 has been paid in dividends to the shareholders. The reserve of ore at the end of June is estimated at 8,869,700 tons averaging 8.4 dwt. per ton over a stoping-width of 67 inches, this being sufficient to supply the mill for seven years. Last year the company received £464,600 in extra revenue thanks to the discount on sterling.

MEXICO is to the front again in a mining way, and we are right well pleased that it should be so. We have published recently several articles on the mining districts of that country and in this issue we give a description of the El Tigre district, which is known chiefly through the successful career of the El Tigre, or Lucky Tiger, mine. The geology of this part of Sonora is rich in variety and in suggestiveness to the student of ore deposits. Mr. R. T. Mishler, the manager of the El Tigre mine, is a technician whose methods are truly scientific in their carefulness and consequent accuracy, so that we can commend the article heartily to mining engineers interested in that part of Mexico.

DR. COTTRELL, it is announced, intends to retire as Director of the Bureau of Mines at an early date, probably in December, in order to give his time to research work as a member of the National Research Council. When he accepted the appointment it was on the understanding that he would serve temporarily, pending the selection of a permanent chief. We understand that Mr. H. Foster Bain, who is now in China, has been approached officially with a view to his appointment. We hope he will accept it, for he is already familiar with the work, having served as assistant to Dr. Manning, and he is admirably fitted in other ways for the directorship.

AT a time when hod-carriers are better paid than school-teachers, and when therefore first-rate men and women naturally seek other vocations, it is well to recall what Roger Ascham said in 1565, three and a half centuries ago: "It is pity that commonly more care is had, yea, and that among very wise men, to find out rather a cunning man for their horses than a cunning man for their children. They say nay in word, but they do so in deed. For to the one they will gladly give a stipend of 200 crowns by the year and are loath to offer to the other 200 shillings. God that sitteth in heaven laugheth their

choice to scorn and rewardeth their liberality as it should. For he suffereth them to have tame and well ordered horses, but wild and unfortunate children, and therefore in the end they find more pleasure in their horses than comfort in their children." Doubtless the laughter in the heavenly places finds a sardonic echo in complementary quarters supposed to be down below somewhere. Hardly less anomalous is the spectacle of a State that spends millions on a university where its young men and women undergo instruction and some process of education for three or four years only to be debauched intellectually for thirty or forty years by the daily influence of a contemptible press.

LAST week we quoted sundry statistics on immigration. Several causes have joined to check migration from Europe; one of them is the cost of travel. The head-tax in 1882 was 50 cents; it is now \$8. Every immigrant has to pay \$10 for an American consular *visé* of his passport. In 1913 the total cost, for steamship ticket, consular fees, and head-tax, ranged from \$34 to \$48, according to the European port from which the immigrant sailed; now the cost ranges from \$98 to \$125 per person, but owing to the fall in foreign exchange, the immigrant has to pay an amount equivalent to \$200 if he comes from Helsingfors or Copenhagen, and not less than ten times as much if he comes from Trieste. Moreover, he makes more 'money' at home than he did in 1913 and he has to pay more for railroad travel if he comes from inland, besides additional consular fees if he has to cross one or more frontiers in order to reach his port of embarkation. The literacy test, enacted in 1916, excludes many that would otherwise come. Mr. Frank-Plachy, editor of the monthly magazine issued by the National City Bank, estimates that existing shipping facilities will not permit more than 750,000 immigrants to enter this country during the fiscal year ending in April 1921. During August the heavy immigration recorded in the three previous months showed a slump, to a net gain of 12,249, as compared with 21,373 in July. The net number of immigrant males arriving at the present time is at the rate of only 80,000 per annum.

CROPS are splendid, and they are being moved to market without undue financial dislocation. For this last we can thank the Federal Reserve system. The assurance of a large supply of grain in the country and in Canada has depressed prices naturally. Cotton is down because the textile trade, all over the world, is disorganized. The same applies to wool. Manufactured products have slumped in price. The era of fictitious values is nearing an end. Many are being hurt. It is not pleasant. Somebody must pay the piper and the tune sounds like a discord. That incorrigible ratio of supply and demand has a nasty way of asserting itself at inconvenient moments. Abundant harvests are as food to one man and poison to another. Falling prices bring tears here and smiles there. Even unemployment is not an unmixed evil if it makes organized labor pause in its excessive demands and realize that there must be an end

to profiteering of service as of commodities. We need more homes for the people and cheaper food for those living on a narrow margin. It is time the country settled down from its orgy of price inflation. In any event, whether we like it or not, the time has come. There is suffering whenever economic changes come into effect violently, but come they must if human greed uses economic causes as an excuse for predatory business. Some day we shall establish some agency that will check profiteering as we now try, but not with much success, to check combinations in restraint of trade. In the civilization of a later day those who seize society by the throat in order to force excessive prices will be disciplined, without, let us hope, stifling legitimate competition.

OUR New York correspondent, on the page devoted to the Eastern Metal Market, has referred more than once to the fact that the lead market has been threatened with shipments of metal from Europe. German lead has been offered at 7 cents, duty paid. This prompts our contemporary, 'The Wallace Miner', to appeal for a tariff on lead in order to exclude the metal produced by the cheap labor of Europe. With this plea we sympathize, but we have reason to believe that our friend in the Coeur d'Alene is weeping over the wrong tombstone. It is not cheap labor, but cheap money—cheap as dirt—that is the cause of the trouble. The German who sells his lead for seven cents will convert the seven cents United States currency into four marks or more, this being 15 times the rate of exchange that obtained before the War. Thus the price of his lead is multiplied fifteen times, whereas the cost of the labor required to produce it has not been more than quadrupled. In plain English, the enhancement of the dollar has created a bridge for European exports and a corresponding barrier to imports from us. This is only one more of the annoying economic consequences of the present abnormal state of international affairs. Some of the dealings in foreign lead may be due to speculation in exchange and the re-selling of metal previously sold to brokers on the other side. Last week we recorded the fact that the Consolidated Mining & Smelting Company of Canada presented a plea, to the Canadian Tariff Commission, for protection against imports and asked for an increase of the duty on pig-lead from one cent per pound to two cents. We may add that in 1913 the German production of lead was 181,100 tonnes (or metric tons), all of which and more was consumed at home, the total German consumption in that year being estimated at 246,000 tonnes. Just now the Germans must have need for all their lead and it is only the adverse credit position that excuses the exportation of it to us.

IN the 'El Paso Morning Times' we have read the report of a speech made by General Ignacio Enriquez, the Governor of the State of Chihuahua. He is a member of the class of 1910 in the University of Illinois and speaks English well, so that he is in a position to understand the American point of view. The Governor gave

utterance to many friendly sentiments; among others he said: "Our most ardent desire, as Mexicans, is to see that justice is accorded the foreigners who have aided so materially in the development of our country, but we are equally desirous of being treated fairly by other nations. With the idea of equity in mind, all the difficulties and misunderstandings could be easily solved." We hope they will be solved, even if the task be more difficult than it may seem on the occasion of an excellent luncheon at the University Club of El Paso. Certainly, goodwill and the desire to be fair will go a long way toward the desired consummation. On the same occasion General Alvaro Obregon, President-elect of Mexico, spoke briefly, and in Spanish, although we understand he also has an easy command of our language. He said: "We invite to Mexico such men as wish to work unselfishly for the well-being of all, both for themselves and the Mexicans, but we don't want men prompted by the speculative vice who seek only selfish self-profit". This is the translation by the interpreter present at the time and it may be faulty. Vulgarly speaking, it is 'guff', hardly worthy of a direct-acting soldierly leader. We fear that not many of our people can claim to be so altruistic and we shall forgive them if they are sceptical as to the actuation of their Mexican friends by motives so nearly angelic. Mining, we can say frankly, is usually actuated by "the speculative vice of selfish self-profit", and not by Sunday-school maxims or scientific idealism. We note 'The Financial Times', of London, sent a cablegram to General Obregon asking "the probable attitude of himself and his government toward foreign capital invested in the country". He replied personally as follows. "I have received your cable of the 8th September and can assure you that the new Government of Mexico will give preferential attention to its commitments abroad, will treat them with all seriousness, and will afford protection, in accordance with our laws, to all foreign capital invested in Mexico, or which may be so invested in the future."

The Election

The election of the next President takes place in a few days. Of two things one can be certain, the first is that he will come from Ohio, and the second that his election will not be acclaimed with any great enthusiasm by the more thoughtful even of his own party. In truth, there has rarely been a presidential campaign so uninteresting and unsatisfactory. Thanks largely to our method of selection, by a mob in convention assembled, the two standard-bearers are men of no intellectual power. Their statesmanship appears to be on a par with their golf, and their political poise seems no better than their pose at the end of a drive. We have seen photographs of both gentlemen taken in the act: head up, weight on the wrong foot, club pointing skyward, and other sure evidence of a fizzle. The betting is that the little white ball has been sliced into a bunker eighty yards on the right. Both owe their nomination to what are called political bosses, for the good reason that no assemblage of a thousand dele-

gates can hope to make a selection except through a caucus of leaders. The attempt to split the parties on the issue of the League of Nations appears to have failed, for although Mr. Harding has no use for the existing League, he is being supported by Mr. Taft and Mr. Hoover, who were at one time uncompromising supporters of it, and by Senators Johnson and Borah, to whom it is anathema. The issue is President Wilson's administration, not the League; in short, it is a choice between the 'ins' and the 'outs'. As Mr. Hoover says, "the solemn referendum is not on the League, it is on the failure of the Democratic party". He and other progressive men prefer to support a reactionary Republican rather than run the risk of keeping the Democrats in power. As a matter of fact, the conduct of the War by the Democratic administration was distinctly more creditable than the performance of McKinley's administration during the Spanish war; that was marked by inefficiency and scandal of the grossest kinds, whereas the record of the Wilson regime during the recent war is comparatively free from the larger blemishes of stupidity and corruption. The country has no reason to be ashamed of its performance; it compares well with the records made by the European governments during the same critical period. The chief fault of it was that it was done with the apparent purpose of making it rebound to the fame of one man and to the prestige of one party, instead of allowing the credit, like the effort, to be national. President Wilson played a poor game because he played a lone hand; he made the further blunder of estranging the best men in the Republican party by disregarding their desire for co-operation during the War and by ignoring their willingness to collaborate in the making of peace. When he delivered his message declaring war he should have called such men as ex-Presidents Roosevelt and Taft to his councils, possibly also Messrs. Root and Hughes, forming a coalition cabinet and thereby putting party considerations aside for the sake of the bigger and vastly more urgent duty that he had to perform as Chief Executive of the nation. He failed to rise to the occasion; he played small politics; he irritated his opponents; he flouted the Republican party; hence the bitter and unjust criticism, and even vilification, to which he has been subjected. History will do justice to his lofty idealism and to the other fine qualities of his statesmanship, but for the present he is the target of obloquy, much of which he has brought obtusely upon himself. He tried to claim all the renown and all the credit for himself and his party; to him and to his party therefore all the mischances and all the mistakes are being debited. The majority of the voters will agree with Mr. Hoover when he says: "It is fundamental when a party fails in statesmanship or fails to carry out its promises, it must accept the penalties of that failure; it should be retired in order that its leadership may be reformed". To this it may be replied that Governor Cox does represent a new leadership, but, unfortunately for him, he has to carry the incubus of the unpopularity of the President. Mr. Cox said to a heckler in Kansas:

"My friend, Wilson isn't running for President. Cox is running for President." It is true Governor Cox was nominated by the Democratic convention, but he is running on a platform that unreservedly endorsed President Wilson's administration. He must share its unpopularity. If the Democrats had nominated a man of real distinction, one who could command the confidence of the independent voters, they might have defeated Senator Harding. They failed to do so. Mr. Cox is cleverer than his rival; he can make a better speech, but he is too glib, he has promised too many things irresponsibly to be trusted in the high office to which he aspires. Indeed, the choice of candidates is lamentable. Moreover, there is no third-party leader for whom the independent voter can cast his ballot with any self-respect. That may be fortunate, for our theory of government is based upon a two-party system, and we have no desire whatever to see it degenerate into the welter of confusion that characterizes the conflict of three or more political groups in the legislatures of Europe. At the close of the campaign the issue has narrowed down to a party basis; the larger questions are in the discard; even the Republicans who wanted to overthrow the unrepresentative system that caused the nomination of Senator Harding are willing to postpone an attack upon that system until their party is safely in power; even the Democrats who know Governor Cox's wretched war record will vote for him in order to endorse the Wilson administration. On that they will go to defeat. For ourselves, we ought to be pleased to see Mr. Harding elected because he and his friends undoubtedly will look after the welfare of the business interests, including those of publishers, but, looking at the Presidential election in a worthier way, we regret that he could not be opposed, and defeated, by a man of keener intelligence, of robust character, and of more liberal ideas.

A New Mineral

Queer things are found in nature, particularly where chemical and physical forces have operated with abnormal intensity, as in Nevada. From that great mineral region there comes the news that an enterprise has been launched of which it may be said, in the words of a South Sea Bubble prospectus, that it is "a project the nature of which will be later divulged". However, we would deem it unkind to withhold even our present incomplete information from a world eager for enlightenment. We are told that a discovery has been made more important in a truly economic sense than that which made the Busted mountains famous in the early days, or the celebrated Hallelujah Consolidated, whose search for oil in the obsidian of the Never-Never land has excited keen interest among geologists. The enterprise to which we refer is already the subject of excited conversation in every mining community in Nevada; it is called the Wet Products Corporation and its promoters are said to control 25 claims covering an immense deposit of 'hoochite', or 'hoochspar', a mineral containing a large percentage of alcohol. The deposit is covered by a flow of lava, a

variety of dolerite, but its existence was disclosed by a natural spring. It appears that Blinkey McGuire, the well-known prospector, happened to see a coyote in hot pursuit of a rabbit, which stopped and took a drink at the spring. The chase was resumed, but, much to McGuire's astonishment, the rabbit turned on the coyote and attacked it savagely, compelling it to retreat. The rabbit jumped, tumbled, and rolled, as if in an ecstasy, and then started after the coyote with such speed that its tail was extended horizontally. McGuire, being of a scientific turn of mind, was curious. He examined the spring, and, being an experienced prospector, he had no difficulty in detecting the familiar odor of a venerable corn whiskey. He took a sample with him for analysis at Goldfield, where his surmise was confirmed. Returning to the spot with several mining engineers, who were willing to assist him in a scientific study of the deposit, it was ascertained that in an earlier geologic period the valley and the surrounding hills had been covered with vast corn-fields, probably in the Carboniferous period, when vegetal growth was so abundant. A flood had swept the corn into the central part of the valley and a flow of lava had buried it completely, as in a retort. Heat and pressure, during long geologic time, had consolidated the decaying corn into a soft yellowish mineral, now known as 'hoochite', or 'hoochspar', which at one place, where the lava is fractured, has been dissolved by the ground-water and brought to the surface as a medicated spring. This opening has been cemented already in order to prevent further wastage. The deposit itself, judging from the local stratigraphy, lies at a depth of about 2739 feet, and a drill-hole is to be sunk to it, with suitable preparation for closing it with a valve so as to regulate the flow of precious liquid. Whether it will be advisable to sink a shaft in order to mine the solid hoochite or whether the deposit can be extracted by leaching it, as is done in salt mines, or by admitting live steam and melting it, as is done in the exploitation of sulphur, for example, is not yet decided. We are informed that a market is assured at \$25 per quart of solution or \$250 per pound of 65% hoochite. Preferred stock has been placed on the market, the immediate consequence being a big drop in the quotations for Liberty bonds at Goldfield, Tonopah, and Virginia City. Government officials are on the ground already and the U. S. Bureau of Mines has sent a mine-rescue team to the locality, with oxygen helmets, in case the fume of the hoochite should overcome the force of men now engaged in preliminary operations. Undoubtedly this will prove an important addition to the mineral resources of Nevada; it may prove as important as the layer of soapstone discovered a few years ago near Lovelock; it was a kind of ozokerite and proved so useful in removing the stains on the escutcheon of the State that the State Treasurer, on the suggestion of George Graham Rice, changed the motto of the commonwealth to 'While there is life there is soap'. Since then wash-sales of mining stock on Bush street have been conducted with a success that has aroused the admiration of the State Commissioner of Corporations.

The Geology of Brazil

The Editor:

Sir—In the bulletin of the Geological Society of America of June 30, 1919, there was published a paper entitled 'Outlines of the Geology of Brazil to Accompany the Geological Map of Brazil', by John Casper Branner.

The appearance of this map and sketch is a notable event worthy of more notice than it has received and its title would connote, for it not only possesses great merit as a contribution to geologic literature, but is also of the utmost practical value to the mining engineer interested and engaged in the economic development of this enormous country. In a sense it may be regarded as the culmination of the life work of one of our most distinguished, careful, and competent geologists, a sort of *magnum opus* the result of years of hard work and study for the mere love of it. It is true Branner was in the service of the Brazilian government in various capacities for a number of years, although he appears to have been insufficiently sustained by the authorities. But to him, with the possible exception of Orville Derby, we owe more than to anyone else the only clear and comprehensive conception it is possible to obtain of the general geologic character of Brazil.

Save in a few localities, Branner's work makes no pretense of detailed accuracy, indeed it could not be otherwise of so enormous a country not yet wholly explored even in a geographic sense. Some of the States, such as Minas Geraes and Bahia, are comparatively well known and mapped with some degree of accuracy and it is to such localities more than elsewhere I would like in a few words to direct attention.

When the Portuguese made their first settlements in Brazil, gold mining, or rather gold-washing, became one of the occupations to which they devoted much attention and from which they derived considerable wealth. As a consequence the operations were large and the hinterland back of Rio de Janeiro settled rather rapidly considering those primitive times, the name Minas Geraes resulted from this circumstance. The discovery of diamonds followed later (about 1725) and Brazil became, for those days, the second great diamond-producing country, India being first.

In some respects Brazil reminds me of China as I first knew that interesting country in the year 1900, and Branner bears much the same relation to Brazil as Richthofen does to China in making known to an ignorant and then little interested world the mineral resources of the three or four great untapped reservoirs of raw ma-

terial now so badly needed in this industrial-plagued planet.

In Brazil, however, unlike China, two of the most important factors of our so-called modern civilization are conspicuous by their absence, namely, coal and petroleum. Of the first there is a modicum to be found in the Permian rocks of Rio Grande do Sul. Very high in ash and of low calorific power, these coals must be washed and treated to be successfully made into coke. The Carboniferous formation is by no means wanting among the rocks of this vast country, but so far no coal-bearing measures belonging to them have been discovered nor does it seem likely there ever will be.

Of petroleum there are few indications, but when one considers the vast size of the country and how imperfectly many parts have been explored in a geographic sense, not to say prospected in a mineral way, it is obviously unwise to have any opinion regarding the matter. Curiously enough, however, petroleum's first cousin, oil-shale, is abundant along the coast of Brazil, being found in the Eocene-Tertiary rocks that extend from the Amazon on the north along the coast south nearly to Rio de Janeiro, a distance of almost two thousand miles, with but few breaks or intervals in their continuity. Almost anywhere in this Tertiary area, oil-bearing shales might be expected, but so far they have been located and definitely identified in but a few localities, probably for the simple reason that no systematic search has been made for them. In thickness these beds of shale vary from six to twelve feet and yield as much as forty gallons of oil per ton of rock.

The lack of fuel in Brazil is almost tragic in its seriousness. Here we have one of the largest countries of the world with a stable government, vast natural resources of many different kinds and iron-ore deposits unsurpassed, if indeed equalled as to quality and quantity, wholly dependent upon foreign sources of supply for coal and coke, which inland is practically at a prohibitive price. Such conditions preclude the establishment of iron and steel industries, which must necessarily be the basis of modern industrial progress and logically the result of such enormous local supplies of raw material other than fuel. What may be expected of electric smelting in this connection is conjectural, of course, as the state of the art is hardly sufficiently advanced to form any definite conclusion; such is certainly the case with iron, however satisfactory the results may be in smelting other metals. Brazil affords many opportunities for the installation of hydro-electric power plants, some of great size and in fairly convenient localities. Doubtless the

solution of her difficulties in establishing a large metallurgical industry is to be found in this direction.

One is impressed in studying Branner's map by the immense area of Archean rocks that constitute the eastern part of Brazil. They are practically continuous north and south from about latitude 2° S. to 32° S. and in places the belt is hundreds of miles wide from the coast westward. These old rocks, especially when associated with the early Paleozoic and Silurian formations, are likely to be important depositories of metallic minerals. Thus, for example, in Minas Geraes we find rich iron ores as well as manganese ores affiliated with early Paleozoic sediments. The best and largest manganese deposits appear, however, to favor the crystalline schists and limestones of the Archean, and, naturally, one would look for the chrome deposits in the serpentine and gneiss of this comprehensive and welcoming group of rocks to which is relegated everything in the way of formations too old for positive identification. The famous Morro Velho gold mine, belonging to the St. John del Rey company, is in the Archean, the lodes consisting of lenticular shoots of quartz intercalated in the country-rock. The quartz contains, in addition to gold, varying amounts of pyrite and pyrrhotite, together with carbonates of lime, magnesia, and iron. The most extraordinary thing about this mine is the persistence of the precious mineralization, it having now been proved, with relatively slight change, to a depth of considerably over six thousand feet, this being the deepest gold mining in the world. It is a notable fact that not one of the other gold mines of Brazil has approached the Morro Velho in magnitude and importance; undoubtedly the operation of the property has been skilfully and determinedly conducted, which may account for its predominance, for of all classes of metal mining that of gold demands the highest degree of skill and pertinacity.

A noted peculiarity of the Archean granites of Brazil is the presence in many of them of a rare group of minerals containing cerium, lanthanum, zirconium, and thorium, the last being the oxide from which incandescent gaslight mantles are made.

In considering general mining conditions in South America, the mind naturally turns to those countries whose mines have achieved historic distinction, if not fame. The world has long since heard of the gold of Antioquia (Colombia), the probable source of most of the gold of the Incas, the silver of Potosi (Bolivia), and the copper of Chile, to say nothing of the emeralds of Muzo (on the Bogota plateau, Colombia) and the tin of Bolivia. But except for diamonds, an almost insignificant industry as compared with that in South Africa, very little is heard of the mines of Brazil, despite that today this country contains the greatest reserves of iron ore known to an extravagant and wasteful civilization. As a producer of minerals Brazil is today a negligible factor, for even its manganese, the only ore exported in quantity, is not indispensable, for it is no better than the Indian and not so good as the Caucasian.

The publication of this splendid geologic map of

Branner's is therefore most opportune, giving as it does to the mining engineer a welcome insight into the possibilities of this vast unexploited and undeveloped territory, a country full of promise in meeting the demands of an expectant industrial world, a Europe almost drained of its mineral wealth, and a North America doing its best to follow suit. On the whole, the mineral resources of Brazil assure an enduring character. As we know, the iron deposits are unsurpassed; of copper, there are indications of much; and of manganese, chrome, and gold there are positive proofs that extended explorations and prospecting will result in the discovery of many new deposits of a commercial character.

If the technical and practical difficulties in the economic treatment of oil-shale can be overcome successfully, as no doubt they will be, a domestic fuel-supply is assured, not to mention the by-products as an indirect source of wealth and an aid to agricultural industry by reason of the production of ammonium sulphate. An independent supply of fuel, gasoline, lubricants, and fertilizers would thus be obtained as the result of the development of one heretofore wholly neglected mineral product whose value has until now been almost wholly unsuspected, or at any rate never regarded of sufficient importance to demand Government aid in its exploitation.

The unselfish and devoted work of Branner in Brazil is sure to be progressively appreciated as the years go on and the virgin areas he so conscientiously sketched and mapped, crude and rough though much of the work must necessarily be, respond to the touch of development and detailed study under the direction of the economic geologist and mining engineer. He has laid the foundations in this geological map, something substantial to build on, a thing no other South American country possesses, except possibly British Guiana, where an enlightened progressive government and J. B. Harrison, a geologist of the Branner stamp, have given us an excellent series of reports and maps of a country, although very much smaller, yet quite as difficult to explore as the Amazonas of Brazil. All honor to such men as these two, veritable pioneers of science, blazing the way and making smoother the path of those who follow after. Honor and satisfaction for difficult work well done is probably all the reward they can expect, and it is pretty certain it is all they will get from a world that has ever thus recompensed its greatest benefactors.

F. LYNWOOD GARRISON.

Philadelphia, September 21.

THE United States is still dependent on foreign countries for its supply of platinum. The total quantity of refined platinum and allied metals recovered from foreign and domestic ores by domestic refiners decreased from 59,753 oz. in 1918 to 45,109 oz. in 1919. Only 11,759 oz. of refined platinum was derived from domestic ores in 1919. On the other hand, the imports of platinum and allied metals increased from 56,753 oz. in 1918 to 68,054 oz. in 1919, nearly half of which came from Colombia.

Geology of the El Tigre District, Mexico

By R. T. MISHLER

GEOGRAPHY. To furnish a framework upon which to hang the geology, a brief outline of the geography of the surrounding country is necessary. The Tigre (or 'Lucky Tiger') mine is situated in the north-eastern part of Sonora, Mexico. The elevation is 5800 ft. Four miles north of El Tigre is Pilares de Teras, where are the Cinco de Mayo and Roy mines. Two miles north of El Tigre are the North Tigre and Santa Maria mines.

The district lies on the steep western slope of the Teras range of mountains. It is traversed by several deep canyons, all flowing west. The Bota is the deepest; it is three miles north of El Tigre and separates the Pilares and North Tigre districts. A branch of the Bota canyon has its source behind Tigre peak, the high mountain a mile east of the town.

At the north edge of the town is the Combination canyon; at the south edge is Espuelas canyon. The two join at the mill to form the head-waters of the Chinosos stream. A mile south of the town is the Tigre canyon. This is a branch of the Otates arroyo, which drains the west flank of the Teras range as far south as the Temblor mine. On the east side of the range the Pita canyon is the largest and deepest. The Pita stream flows east and empties into the Bavispe river near the town of San Miguel. Here the Bavispe flows north, between the Teras and Sierra Nevada ranges. Thirty miles north of El Tigre the river makes a loop around the north end of the Teras range and flows south, receiving the waters of the Bota, Chinosos, and Otates streams, before joining the Aros to form the Yaqui river.

A rectangular area, including the principal claims of the Tigre Mining Company, was selected for detailed geological work. This area is roughly two miles long (north to south) by one mile wide. It extends from Palomitas canyon on the north to the South Tigre workings on the south; and from the mill on the west to the charcoal kilns on the east.

GENERAL GEOLOGY. During Mesozoic time the region about El Tigre was a rolling plain, covered with fluvial fans fed by the erosion of the granite and limestone. Probably this surface was fairly close to sea-level, for only 20 miles west are thick beds of calcareous shale, which appear to have been deposited during the Mesozoic era.

Portions of the old surface are found at several places. The most conspicuous of these is the level bench above the dark rock on the hill north of the mill. The mill itself is on the granite, at a considerable distance below the Mesozoic surface; the old surface as well as all overlying strata having been trenced during recent time by the Chinosos stream. It is interesting to note that stratigraphically the mill is at the lowest point for miles roundabout.

The Tertiary era was an age of intense volcanic activity. The old surface was covered with successive flows of rhyolite and rhyolite tuff; the whole series aggregating 4000 ft. in thickness. This volcanic rock constitutes the main part of the mountains about El Tigre.

The lowest flow of lava, called locally the 'Nodular' formation, was laid down early in Tertiary time. After its formation, volcanic activities ceased for a while; Minor drainage systems were formed and an extensive lake was developed, with its centre where the town is now. The bed of the lake became filled with shale and thin layers of limestone. Later a new volcanic era was

MAP OF PART OF MEXICO

ushered in by showers of volcanic 'ash'. These formed beds of tuff, blotting out the inequalities caused by former erosion and covering the old lake-bed to a depth of 500 ft. Finally, a single flow of lava, 250 ft. thick, was poured out upon the tuff and overspread the whole district. The tuff and calcareous shale have received the local name of 'Flat' formation. The massive lava-flow is called the 'Cliff' formation. It constitutes the escarpment just above the town.

Following the deposition of the Cliff lava, there was another lull in volcanic activity, during which 50 ft. of wind-stratified tuff was laid down. Then followed the most intense period of volcanic activity. Flow followed flow, until a mass of lava 2500 ft. thick had been piled upon the tuff beds. The various flows have been differentiated according to their physical characteristics and, from bottom to top, have received the names of 'Tigre', 'Upper Tigre', 'Quartz-Rhyolite', 'Quartz-Mica Rhyolite', and 'Glassy Rhyolite'. The last constitutes the last

GEOLOGICAL SECTION OF

of the volcanic series and is found only on the mountain-tops.

Near the close of the volcanic era, the district was raised to approximately its present elevation, the sedimentary strata and lower volcanic flows being tilted to the south at an angle of 15° . The tilting, and possibly the uplift, were completed before the end of the volcanic period, for the upper flows are all thickest toward the south, thus equalizing the effect of the dip in the lower strata. At the close of the volcanic era, the region was probably fairly flat, with the surface at the height of the present mountain-peaks.

During the period of uplift the region about El Tigre was subjected to minor fracturing and faulting. Through the faults and fractures welled up metal-bearing solutions, which altered the rock of the lower members of the volcanic series and formed veins.

During and after the deposition of ore, the country was dislocated by extensive north-south faults and minor east-

west faults. Andesite rose through the faults, forming dikes and stocks, and overflowing in places to form minor flows.

The general blocking out of the mountain ranges was effected by the north-south faults. Erosion followed and carved the mountains to their present shape.

DESCRIPTIVE GEOLOGY. The oldest sedimentary rock exposed in the district is limestone. From similarity in character and position to the Carboniferous limestone of Arizona, it has been classified as belonging to that period. It is fairly pure, of grayish blue color, and occurs in thick beds with a general dip of 30° west. Outcrops of limestone are found in the beds of Pita and Bota canyons, at Pilares de Teras and at the lime-kilns a mile west of El Tigre. Although the limestone does not outcrop within the Tigre quadrangle, its occurrence on three sides leads to the supposition that it underlies at least a part of the quadrangle.

Outcropping at the same general horizon as the lime-

THE EL TIGRE DISTRICT, IN SONORA, MEXICO

stone is an intrusion of granite consisting mainly of microcline, sanidine, quartz, and phlogopite mica, the last now largely changed to serpentine and iron oxide. It is probably late Paleozoic. The granite is exposed in the canyons near the Tigre mill and also in Palomitas and Pita canyons. It probably underlies the greater part of the Tigre quadrangle.

The Nodular formation is the lowest member of the volcanic series. It was originally a glassy lava containing aggregates of spherules. The groundmass is now much kaolinized. The spherules are remarkably well developed, occasionally reaching a diameter of 18 inches. In places they are crowded so close together as to give the rock the appearance of a conglomerate. They are usually separated from the kaolinized groundmass by films of limonite or gypsum. Unaltered specimens contain 75% silica. The rock is classed as rhyolite.

Overlying the Nodular formation is a bed of rhyolite-tuff and calcareous shale; locally this is termed the Flat

formation. It is 500 ft. thick at El Tigre, but diminishes in thickness in all directions from the mining camp. The tuff is well stratified, indicating that it was deposited under water. The binding material is secondary calcite and quartz, the latter predominating. In many places the deposition of secondary silica has been so intense as to obscure the tuffaceous character of the original rock, only slight tabular parting remaining along the original bedding-planes. Silicification is especially noticeable in the bottom of the formation and along old fissures and veins. Unchanged specimens of the tuff contain 71% silica, indicating that it should be classed as rhyolite.

The Cliff formation consists of a massive flow of fine-grained rhyolite, 250 ft. thick. It shows small phenocrysts of sanidine and quartz in a felsitic groundmass. The most important mine-workings are now in this formation. Near the vein-systems the formation is criss-crossed by minute quartz veinlets. The silicified rock is the hardest in the region and is being used with success

in the tube-mills. The Cliff formation contains 80% silica and is classed as rhyolite.

Overlying the Cliff formation are beds of rhyolite-tuff, aggregating 60 ft. in thickness. It is always greatly altered, is the softest rock in the region, and is characterized by containing large cubes of secondary pyrite. Some of the best orebodies have occurred in this formation. The tuff contains 71% silica, indicating that it should be classed as rhyolite.

The Tigre formation is a flow of rhyolite, 400 ft. thick, in which occurred the principal orebodies of the upper part of the mine. It is a medium-hard porphyritic rock with abundant crystals of sanidine and quartz in a felsitic groundmass. Pyrite, in small cubes, is abundant, especially near the veins. The Tigre formation contains 72% silica and is classed as rhyolite.

Overlying the Tigre formation are the Upper Tigre formation, quartz-rhyolite, quartz-mica rhyolite, and glassy rhyolite. All are porphyritic, containing crystals of sanidine, quartz, and mica in a glassy groundmass. The silica content ranges from 68% in the Upper Tigre formation to 81% in the quartz-rhyolite. No ore of commercial importance has been found in any of these flows.

Cutting through all the rocks of the region are a number of andesite stocks and dikes. One dike was intruded along the Sooy vein after ore deposition was complete. The North Tigre deposit occurs in a sill of this andesite. The wide distribution of andesite dikes along the whole Teras range and the occurrence of large bodies of andesite in the deeper canyons indicate that the andesite constitutes the core of the range. It seems possible likewise that the intrusion caused the faulting and general blocking out of the range, and may have been responsible for the ore deposition. The rock consists of minute laths of labradorite, interspersed with grains of augite. It contains 52% silica and is classed as augite-andesite.

Faults are numerous and in places produce dislocations of several hundred feet. All those observed are normal, that is, when the fault-plane is inclined, the upper side (or hanging wall) has slipped downward. All the major faults traverse the country in a general northwest-southeast direction, parallel to the axis of the range. Minor displacements cross the district in various directions.

The veins themselves are minor faults and represent the first fracturing in the region. While ore deposition was in progress, the south end of the main vein was intersected by a series of faults parallel to the vein, but dipping at a steeper angle westward. The total throw aggregates 200 ft. The best ore has been found near these faults. During the same period the north half of the vein was dislocated by three east-west faults, each with a throw of 50 ft. south. The principal deposits in the north half of the mine have occurred near these faults. In general the ore occurs in fractures and faults dipping west and is associated with fractures and faults dipping west and south. Faults dipping east or north were later than ore deposition and have no relation to it.

By far the greatest dislocations of the region have occurred during comparatively recent time. Two great

fault-systems traverse the country in a northwest-southeast direction. The larger cuts diagonally across the south-west corner of the quadrangle, extending for miles along the foot of the high mountains. The entire western flank of the range has slid downward along this fault, the displacement ranging from 1500 to 3000 ft. This fault has been re-opened twice since 1880, both these reopenings being accompanied by severe earthquakes. The second largest fault traverses the centre of the quadrangle, passing between the mine and the mill. The east side has been dropped 500 ft. The two great faults have depressed both the central ridge and the western flank of the mountain range, leaving an intermediate zone stratigraphically higher than the formations on either side. The resulting inequality of the surface has been pared off by erosion till the zone is lower than the depressed areas. This explains why the oldest rocks of the region are found in the eroded area surrounding the mill, whereas the districts both east and west are composed of more recent lava-flows.

Three late faults cut the main vein. They all dip north. The throw is also to the north and ranges from 150 ft. for the two northernmost to 400 ft. for the most southerly. All three have dislocated the vein and have caused some confusion in the development of the mine. All are normal, and the recognition of this fact has aided materially in the solution of the fault problems.

A simple rule for locating the continuation of faulted veins has been found to apply to normal faults: "If the fault dips from you as you face the end of the drift, cross-cut into the foot-wall of the vein; otherwise cross-cut into the hanging wall." The two words "from" and "foot-wall", beginning with "f", aid in remembering the rule. The rule is not applicable to reverse faults and may not be applicable where there has been a side movement along the fault, or where the vein is nearly vertical and strikes nearly parallel to the fault; but it probably applies to 80% or more of the fault problems encountered in mining. It is suggested as a convenient rule of thumb for the practical miner.

ECONOMIC GEOLOGY. The Tigre mine is essentially a silver-gold property. Silver constitutes 85% of the value and gold 11%. Copper and lead are of secondary importance, each contributing about 2% of the total value.

Since the beginning of operations in 1903, the total ore extracted from the mine has amounted to 700,000 tons, assaying gold 0.25 oz.; silver, 39 oz.; copper, 0.25%; lead, 1%; and zinc, 1.5%. The various shipments to the smelters have aggregated 15,000 tons of shipping ore, 34,000 tons of concentrate, and 290 tons of bullion. The shipping ore and concentrate have averaged 2.7 oz. gold and 390 oz. silver per ton. The bullion has averaged 700 fine in silver and gold.

There are four important veins on the property of the Tigre Mining Company. Named from west to east, they are: the Sooy vein, the Tigre or main vein, the Palomitas-Protectora, and the Seitz-Kelley vein.

All the veins have been deposited along fissures, filling is composed of kaolinized or partly silicified country-rock, usually with deposition of quartz along a

Geological Plan and Section A-A.

El Tigre, Sonora, Mexico.

fissure-planes and in the interstices between the fragments of country-rock. The ore consists of mixed sulphides of zinc, iron, lead, copper, and silver, with their decomposition products. Gold is associated with the copper. The ore occurs in discontinuous lenses of high-grade sulphides, and as low-grade impregnations in the vein-matter. The wall-rock is rhyolite and rhyolite-tuff; it is silicified at points where the veins are highly silicious, and kaolinized where silica is scant or lacking in the veins.

All the veins strike nearly north-south. The Tigre or main vein strikes N. 10° W. The Sooy, Palomitas-Protectora, and the Seitz-Kelley veins are parallel to each other, striking N. 5° E. The dip of all the veins is to the west, averaging 60°.

The Tigre, Sooy, and Seitz-Kelley veins are the only ones in the district that have been worked at a considerable profit. The Tigre has been the most productive, having yielded 90% of the ore so far produced. It extends from a point 300 ft. east of camp to the south slope of Gold Hill, a distance of a mile and a half.

The croppings are insignificant. Sulphide ore appears at one spot only, namely, in the south fork of Espuelas canyon, near the entrance to No. 2 level. Here the outcrop is 200 ft. long and six inches wide. A half-mile south, near the Brown shaft, a rich pocket of gold ore was found at surface. Again on Gold Hill, south of Tigre canyon, low-grade ore outcrops for a distance of 100 ft. Aside from these three insignificant showings, the croppings are scant and practically barren.

The development on the Tigre vein consists of ten levels, driven at 100-ft. intervals. Six only of these are adits.

The ore-channel so far developed on the Tigre vein is a mile long by approximately 700 ft. along the dip. It extends from Espuelas canyon on the north to the centre of Gold Hill on the south. The upper limit of the ore-body coincides with Level A. The bottom limit roughly follows the contact between the Cliff and Flat formations, dipping south in conformity with the volcanic beds. Thus at the north end of the mine, the ore terminates on Level 5, while at the south end good ore continues below Level 8. Within the limits outlined two-thirds of the vein has been ore.

The average width of the vein is three feet. In places it narrows to a mere cleft, elsewhere it widens to 10 or 20 feet.

The Sooy vein outcrops strongly in the Espuelas canyon, just south of camp, the sulphide ore coming to surface. It was at this outcrop that the first discovery was made. The vein is worked in conjunction with the Tigre. The orebody has the shape of an inverted equilateral triangle, 500 ft. on a side. The apex of the triangle rests on Level 8, the base on Level 3½. The ore occurs between the walls of the Tuff, Cliff, and Flat formations. The vein is much shattered, showing evidence of movement subsequent to ore deposition. The shattered condition has permitted surface-waters to come in contact with the sulphides, decomposing them. Much of the ore in the upper levels consists of oxides and carbonates.

Irregular dikes of andesite have intruded into the Sooy vein since its deposition.

The Seitz and Kelley deposits are on the same vein system. The Kelley deposit joins the Main vein just north of Tigre canyon. The junction of the two is poor. The Kelley deposit is disc shaped, 500 ft. in diameter and three feet in average width. The deposits on the Seitz vein are 1000 ft. north of the Kelley deposit. They consist of small lenses, separated by extensive areas of barren vein-matter. The largest lens lies in the north end of the mine at the horizon of No. 2 level. It is elliptical, 600 by 100 ft., the longer axis being horizontal. The vein seldom exceeds six inches in width.

The Palomitas-Protectora vein extends from Combination hill to within a mile of the Bota canyon. From its position, dip, and strike it can be considered as the north extension of the Sooy vein. The deposit exposed in the Palomitas mine is roughly 150 by 50 by 3½ ft., and consists of oxidized ore assaying 0.11 oz. gold and 50 oz. silver per ton. The Protectora (North Tigre) deposit, as developed to date, is 1000 ft. long by 350 ft. deep by 2 ft. in average width. The ore consists of sulphides of zinc, lead, iron, and copper in a gangue of quartz and decomposed country-rock. The silver is associated with gray copper and chalcopyrite. Galena and sphalerite are the predominating sulphides. They assay much lower than at Tigre.

RELATION OF ORE DEPOSITS TO STRATIFICATION. Ore has been found at El Tigre only in the Tigre, Tuff, Cliff, and Flat formations. The deposit at North Tigre occurs in the Flat formation and in andesite. The character of the wall-rock has affected the shape of the ore deposits. In the Tigre formation, the veins are of fairly uniform width, varying from one to five feet, and increasing to greater width only near the intersections with cross-veins. The deposits are continuous for long distances. Branch veins, with the exception of the Kelley vein, are short in extent.

In the Tuff formation the vein is extremely variable in width. In most places it consists only of a tale seam with no ore. At cross-fractures or branch veins the width is sometimes 20 ft. In all cases the deposits are irregular and difficult to follow.

In the Cliff formation the brittle character of the rock has been especially favorable for fracturing. The ore characteristically occurs in two or more veins. Usually both the veins and the walls are hard and firm.

Ore has been found in the Flat formation only in the Sooy vein. Here the deposit was lenticular, 200 ft. in diameter and 20 ft. in maximum thickness. The ore consisted of sulphides of copper, zinc, and lead, in a quartz gangue. The silver was associated with the copper minerals (as is the case at North Tigre) and not with the zinc and lead, as in other Tigre deposits. It is possible that the lower Sooy orebody was deposited at the same time as the North Tigre ore.

There appears to be little relation between wall-rock and the character of the ore. This is especially true as regards the silver and lead minerals. There is perhaps a slightly increased proportion of chalcopyrite and gold

COLUMNAR SECTION OF LOCAL GEOLOGY

in the Cliff and Flat formations. Zinc-blende also is more noticeable in the bottom of the mine, but this may be due to its susceptibility to the agencies of secondary enrichment.

GENESIS OF ORE DEPOSITS. There are two possible explanations of the genesis of the ore deposits.

The first is that the ore deposition was associated with deep-seated granitic intrusions from which the rhyolite flows were derived. Such intrusions have been clearly recognized in the Chitahueca mountain 25 miles to the east. It is possible also that the granite of Pita canyon was of this age, for it is much fresher than the Pre-Tertiary granite at the Tigre mill. The possibility of an extensive intrusion of Tertiary granite beneath El Tigre is indicated by the tilting of the lower volcanics before the extrusion of rhyolite was complete. The tilting of the volcanics could have caused the minor fracturing and faulting associated with the vein formation. The vein-filling could have been dissolved from the cooling intrusion and contiguous rocks. The granitic intrusion unquestionably contained silver, for the rhyolites, derived from it, average 0.1 oz. silver per ton.

The second theory is that the ore deposition was associated with the great post-volcanic intrusion of andesite which underlies the region. The presence of extensive dikes and stocks of andesite near all the large ore deposits is a strong argument in favor of this theory. The occurrence of the North Tigre deposit in andesite proves that ore deposition followed at least the first manifestation of the andesitic intrusion. On the other hand, andesite dikes which traverse the Sooy vein prove that ore deposition preceded at least the last manifestation of the andesitic intrusion. Conceivably the dikes cutting the Sooy vein were derived from the molten core of the main intrusion, after the cooling exterior had caused the formation of the orebodies. The Sooy and North Tigre ores are sufficiently similar to each other and to the ores of the other veins to indicate the same source for all the ores of the region. It can therefore be argued consistently that the ores of the Tigre district were deposited while the andesite intrusion was solidifying and cooling. Thus the andesitic intrusion fills the modern requirement of a cooling igneous intrusion (preferably basic) as the source of the ore-bearing solutions.

The andesite assays 0.06 oz. silver per ton, and the rhyolite, lying between the andesite and the ore deposits, assays 0.10 oz. per ton. The ground-water at Tigre is noticeably charged with alkaline sulphides.

It is not unreasonable to suppose that the veins were formed by hot alkaline-sulphide solutions, which derived their heat and part of their mineral content from the cooling intrusion. Part of the minerals may have been derived from the rhyolite and other rocks overlying the andesite intrusion.

In connection with the above theory it is interesting to note that the volcanic rock beneath the ore deposits have been greatly altered for a distance of 100 yards or more on each side of the veins. The alterations in the Nodular formation take the form of kaolinization and loss of silica in the groundmass. The Flat formation is intensely silici-

fied. In the Cliff, Tuff, and Tigre formations there is extensive deposition of secondary pyrite. The altered rocks assay less in silver than unaltered specimens of the same rock. A possible explanation is that the ascending mineral-bearing solutions were partly confined beneath the shale in the bottom of the Flat formation, and spread laterally through the Nodular formation, following the lines of weakness between nodules and groundmass. The groundmass has been much leached, analysis showing a marked reduction in silica, iron, and silver. After the solution had finally forced diffusion through the shale of the Flat formation, the pressure was reduced sufficiently to permit the deposition of silica, which is so marked in this formation. On diffusing still higher into the Cliff, Tuff, and Tigre formations, the solutions dissolved more metals. Iron, being the predominating metal in the rocks, saturated the solutions and was precipitated as pyrite in the rock itself. The other metallic sulphides, together with the remaining iron and silica, entered the veins in a manner analogous to lateral secretion, being precipitated on encountering the reduced pressure and temperature of the open fissures.

The above theory is suggested because it appears to explain the relation existing between the veins and the pyritization and silicification of the wall-rock. This relation has been so repeatedly verified by development work that it has come to be an axiom that the ore is to be sought at the horizon where pyrite occurs in the wall-rock, and just above the horizon of intense silicification.

SECONDARY ENRICHMENT. Secondary enrichment has only slightly affected the orebodies. Most of the ore is primary. This is especially true in the north end of the mine, where the sulphide grains are completely encased in quartzose vein-matter. Here sulphide ore outcrops and shows little evidence of leaching or enrichment.

Farther south the vein is less silicious, and hence more pervious to water. The upper part of the deposit has been leached to a depth of 200 ft. or more. In the leached zone silver ore usually occurs as chloride; only occasionally as sulphide, where the denser portions of the vein lent some protection to the sulphide grains. In the early days of the district a rich gold deposit was found just south of the Brown shaft. The deposit consisted of native gold in an iron-clay gangue. Little silver was present. On the strength of this discovery the company was called the Lucky Tiger Combination Gold Mining Company. Development in depth has shown the silver to be ten times as valuable as the gold. Only the name of the company remains to show that the discoverers thought they had found a gold mine. Undoubtedly, the original silver minerals of the Brown shaft deposit had been removed by the leaching action of surface-waters.

Beneath the leached zone is an ill-defined zone of secondary enrichment. Veinlets of stromeyerite traverse the wall-rock and the original silicious-sulphide ore. In one case a seam of native silver, a quarter inch in thickness was observed traversing low-grade galena.

MINERALOGY. The Tigre ore consists of metallic sulphides (or their decomposition products) in a gangue of quartz and decomposed or silicified rhyolite. Named i-

order of their preponderance the sulphide minerals are: sphalerite, galena, pyrite, chalcopyrite, stromeyerite, and freibergite. The sulphides are invariably much intergrown. Crystals, apparently pure, show traces of other metals on analysis. The rich ore of the Tigre mine is freibergite or stromeyerite containing lead and iron as impurities. The finely crystallized sphalerite and galena are usually intergrown with minute particles of stromeyerite. Hence such ore is generally high in silver. When coarsely crystalline, sphalerite and galena are much lower in silver. Sphalerite generally assays higher than galena. Pyrite is practically barren of silver.

In the oxidized portions of the veins, the important minerals are native gold, native silver, and cerargyrite (hornsilver). A unique occurrence of gold was found in the upper part of Gold hill; it consisted of a druse of fine gold deposited upon a crystal of hornsilver.

Gold is usually associated with chalcopyrite. There is no fixed ratio between gold and silver. One of the samples richest in gold (900 oz. per ton) contained only 100 oz. of silver. Likewise the high-grade stromeyerite ore is practically barren of gold. Only by averaging the production over long periods can any definite relation be found between the gold and silver. For each ounce of gold produced since the inception of operations, the mine has yielded 162 ounces of silver.

CONCLUSION. The knowledge gained by geologic study has proved of much value in the development of the mine. The study of the stratigraphy of the lava-flows has helped in the solution of fault problems and has served to indicate the horizons at which ore may be encountered. The knowledge of the characteristics of the veins in the various volcanics has made possible more intelligent systems of development and mining. The relation between ore deposits and faults dipping south and west has been another aid in the discovery of ore. Likewise the relation between ore deposits and pyrite in the wall-rock has helped in the search for new orebodies—especially by diamond-drilling. Finally, the fact that the zone of ore deposition lies immediately above the zone of intense liquefaction, has aided in following the trend of the orebodies and in avoiding unprofitable development work.

In conclusion I wish to acknowledge the participation of C. M. Heron in the preparation of this article. He did much of the field-work and prepared the original maps and sections. The petrographic work was done by Professors George D. Louderback and G. H. Cox. I desire especially to thank L. R. Budrow, general manager for the Lucky Tiger Combination Gold Mining Company for authorization of the work and for constant suggestions and criticisms throughout its progress.

SELENIUM is a rare and little-known element principally used to give a red color to glass, such as that used on railroads for signal-lights, and in coloring enameled ware. It is also used to overcome the natural green color of ordinary glass. Selenium is peculiar in being a very poor conductor of electricity in the dark and a fairly good conductor in the light and is used in several elec-

trical devices whose utility depends on this peculiarity. It has been used in telephoning along a ray of light and in transmitting sounds and photographs from one place to another over a wire.

The New Cornelia Co-Operative Store at Ajo

*The town of Ajo is built in the desert and consisted of but a few houses when the New Cornelia Copper Co. started operations. Since there were no stores at Ajo or vicinity the New Cornelia Co-operative Mercantile Co. was established to serve the needs of the employees of the New Cornelia and allied companies. The company advanced the money to erect the store-building and to buy the stock, and assumes all risks. In all, \$85,000 has been advanced, representing the capital stock of the enterprise.

The store is run by a store manager, appointed by the company, who reports only to the general superintendent. A committee of seven workmen, representing the various departments, meet with the manager monthly and make suggestions for the betterment of the service and present complaints which have been brought to their attention. The store is well managed, carries a large and well assorted stock, and is modern in every respect. Prices are at the same level as in the other South-Western mining towns. The mining company does not participate in the profits of the store, but does receive 6% interest on the capital advanced. At the end of the year, after making proper deductions for interest on capital account, depreciation of store equipment and fixtures, and for a proper sum to the surplus account, the rest of the profit is distributed among the employees of the company in proportion to the amount of their purchases.

To participate in the store profits employees must be in the company's employ at Christmas, when the dividend or rebate is paid, and must have worked four months previous to December 20, when the books are made up. When a man quits he forfeits any interest in the dividend-fund that he may have acquired, and it has been found that this rule promotes the stability of the working force besides reducing the cost of living of the regular employees. The following profits have been distributed by the store to date:

1917 (9 months)	\$12,052 to 472 employees
1918	32,777 to 773 "
1919	40,825 to 618 "

The average discount has been 15% and about 70% of the men have benefited. Employees, to receive the rebate, must make purchases on credit and all store-accounts are deducted from pay-checks; accordingly no bad debts are accumulated. The store does considerable cash business with others than employees and the profit from these purchases as well as from the business by the men who have quit the company's service, all goes into the general dividend fund.

*Report of investigations, U. S. Bureau of Mines.

Labor the Holder of the Nation's Wealth and Income—II

By W. R. INGALLS

*The report of the Commissioner of Internal Revenue gives some specific figures for 1916 as compiled from the income-tax returns by persons who had incomes in excess of the statutory exemption of \$3000. We may assume that roughly as the dividing line between the wage-earning and the high-salaried and employing classes. There were some wage-earners who overstepped this line, but their number was only 2304, and their net income of about \$16,000,000 may be disregarded. Besides the corporations reporting, there were 437,036 individuals, comprising investors and speculators, corporation officials and superintendents, manufacturers and merchants, bankers and brokers, engineers, lawyers, physicians, and other professional men, public officials, etc. Here is a distinct grouping of capital and mind as distinct from the mere manual workers. Let us see what they got.

The corporations that made any profit reported an aggregate net income of \$8,765,908,984, but the unsuccessful corporations had a deficit of \$656,904,411, wherefore the real net income of all corporations was \$8,109,004,573.

Individuals engaged in business, trade, and commerce earned \$2,637,474,520, salaried and professional men got \$1,851,276,776, while the income from property (such as rents, interest, etc.) not including dividends, was \$1,724,682,062, making a total of \$6,213,433,358, from which there is to be deducted \$461,243,258 for exemptions that could not be classified, leaving a net individual income in the aggregate of \$5,752,190,100, not including dividends. The dividends received by these classes were \$2,136,468,625, and bring their direct income up to \$7,900,000,000.

The corporations of the country, although reporting a net income of \$8,765,908,984, did not distribute anything like that in dividends. We lack a precise figure for the actual distribution of dividends. Neither the Bureau of Internal Revenue nor the Federal Trade Commission has computed this essential figure. However, David Friday, in a study on 'The War and the Supply of Capital' in the 'American Economic Review' for March 1919, gives this figure as \$3,784,000,000. Professor Friday compared the net earnings and the dividends of a large number of corporations, and applied the factor to the \$8,765,908,984 total net earnings of corporations as reported by the Bureau of Internal Revenue. The number of corporate accounts summarized laboriously by Professor Friday in arriving at his factor was so large that his estimate for the total dividends made in this way may be accepted as highly probable.

I must digress here to point out a fundamental difference in thought between Professor Friday and myself. He assumes that the surplus of net income above divi-

dends is retained by the corporations for the improvement and extension of their properties, and consequently is an annual addition to the wealth of the country, according to which theory it would be a capitalistic deduction from the produce of industry. I dissent from this, and hold that the apparent surplus is used largely for maintenance of property. Every student of corporate finance knows that neither a railway nor a mining nor an industrial company is ever safely able to distribute as dividends more than a percentage of its 'net income'. If it does, sooner or later it comes to grief. Professor Friday shows that in 1911-'14 the corporations paid only 67% of their net income in dividends, and presumably that was an approximate representation of their true earnings.

It is, of course, undeniable that corporate surplus goes to a considerable extent toward the increase of capital. The finances of the United States Steel Corporation are an illuminating example of the upbuilding of a business in this way. But whether such increase of capital be shown in the displacement of 'water' in an original stock-issue, in the cancellation of bonds or in stock dividends, the only thing that counts in the division of income is the distribution of cash dividends. The only deranging condition is that the actual new capitalization of 1915, let us say, may not have fructified in cash dividends until 1917 or 1918.

It was in 1915 that American industry began to experience great profits accruing from the war in Europe. In that year of large earnings our corporations, according to Professor Friday, distributed dividends only a trifle larger than in 1914, but the distribution was only 49.1% of the total net income, instead of the pre-war average of 67%. In 1916 and 1917 there were large increases in the distribution and further declines in the ratio. This shows clearly the point that I have made as to delayed benefit. I think it may be deduced, moreover from Professor Friday's figures that the dividends in 1916, 1917, and 1918 were no larger than they were owing to the fact that large parts of the surplus were put into plants that became useless and into inventories that shrank with declining prices. Many companies know sorrowfully how their noble surpluses of 1918 shriveled in 1919. I feel, therefore, that what concerns us in a study of the division of income is simply what was actually paid in dividends.

But these statistics indicate another interesting and important thing. If the dividends of corporations in 1916 were \$3,784,000,000, the capitalistic and directing classes got only about 56% of that sum. Whither went the remainder? Manifestly it could have gone nowhere except to those classes whose net income was less than \$3000; in other words, to the mass of the people. This leads to the

*From 'The Annalist', of September 20, 1920.

thought of elderly people who have invested their savings and to the wage-earners themselves, and there springs into the mind the knowledge that many workers have invested in the stock of companies, like the United States Steel Corporation, for which they work.

The corporate net income in 1916 was \$8,109,004,573, whereof about \$3,784,000,000 was distributed in dividends, leaving a surplus of \$4,325,004,573. If it be assumed that one-half of that surplus was preserved in such a way as ultimately to accrue to the stockholders, which is a liberal estimate, I think, and that the other half went into maintenance (or was destined eventually to be written off), and if we add in the dividends received by persons of less than \$3000 per year income, we have the following summary:

Received by + \$3000 class	\$7,900,000,000
Received by — \$3000 class	1,647,500,000
Retained by corporations	2,162,500,000
	<hr/>
	\$11,710,000,000

Consequently, it appears as clearly as figures can show that in 1916, out of a national produce estimated at \$45,000,000,000 to \$50,000,000,000 the deduction by persons receiving incomes of \$3000 and upward was about \$7,900,000,000, much of which was ascribable to their own efforts, and by corporations was about \$2,162,500,000, nearly one-half of which was destined to go to persons of less than \$3000 annual income, giving a total of about \$10,000,000,000. Everything else, that is, from \$35,000,000,000 to \$40,000,000,000 or 78 to 80%, was the dividend of the people possessing incomes of less than \$3000, and especially was it the dividend of the wage-earners. They could hope to get the remainder only if they acquired possession of all the capital of the country and had all the talented persons working for them as slaves with the same efficiency that they exhibited in working for themselves, which is a preposterous idea. In such an event, however, the people of the country receiving incomes of less than \$3000 per annum to whom went nearly half of the corporate dividends in 1916, and a larger proportion of the interest on bonds and notes, would simply be deprived of that income which is derived in large measure from their own savings.

Thus we see that out of the nation's produce of about \$50,000,000,000 in 1916 the representatives of capital and land received only about \$7,900,000,000, of which about \$3,775,000,000 was from dividends (\$2,136,468,625), interest, rents, etc., and about \$4,100,000,000 was the result of personal effort in business, trade, commerce, and professional practice. This income by personal effort involves the use of capital to a more or less extent. The manufacturer and trader may use a good deal. The lawyer, physician, and engineer use very little, although their ability to earn is largely based on prolonged and costly education and professional training.

I have made a distinction between the income from agriculture and all other income, for I shall make it clear that radically different conditions exist. According to the income-tax returns for 1916 there were only 14,407 farmers, stock-raisers, orchardists, etc., who made returns; they showed aggregate net income of \$129,642,432.

Agricultural corporations reported \$69,862,431. These returns constituted so small a percentage of the total that they may be disregarded, and it may be assumed that agriculture, engaging the labor of about 14,000,000 men, stands apart from the previous considerations in this paper. The produce of agriculture in 1916, according to the United States Department of Agriculture, was \$9,054,000,000 for crops and \$4,352,000,000 for animals and animal products, a total of \$13,406,000,000, but in these figures there is a large duplication, for a great deal of the product of the fields is fed to animals. According to the census of 1899 about 33% of the crop-value was fed to animals. Professor Friday, in the paper to which I have previously referred, estimates about 30%. I am content to adopt his figure, and assume a net gross value of \$10,725,000,000 for farm products in 1916. The value of pasturage, estimated at about \$1,000,000,000 by the U. S. Department of Agriculture, appears, of course, in the animal products.

From the gross income of the farms must be deducted, in order to arrive at the labor return, the cost of supplies and materials (such as machinery, vehicles, harnesses, tools, fertilizers, binding twine, etc.) that are the products of other industries. There is no way of determining this, and I am here forced to resort to conjecture, using a certain rough basis. An estimate of \$2,725,000,000 for such costs will not outrage probabilities, and will leave \$8,000,000,000 as the reward for the labor of 14,000,000 farmers and farm laborers in 1916. According to these figures, the yield per person was only about \$571, including not only the remuneration for labor, but also the interest on invested capital. Of the 14,000,000 persons engaged in agriculture about 7,000,000 were farmers in their own right, and about 7,000,000 were hired men. Without any doubt the former received more than the latter.

It will be perceived immediately that there is something wrong with these figures. The quotient is manifestly too small. The statistical evidence in favor of the substantial accuracy of the divisor is preponderating. Clearly the dividend is in error, and it is no stretch of the imagination to conjecture that it does not include the produce that the farmer uses for himself and his hired men. Indeed, anybody who is acquainted with the accounting practices of farmers knows that not one in a thousand of them keeps track of this, or could report it. Therefore, it is clear that the farmer is not really so badly off as the figures indicate; that the actual produce of agriculture in the country is greater than the figures indicate; that in considering the position of the country as a whole agriculture and its returns must be segregated, and that having done so we have to deal with a total produce of about \$42,000,000,000 instead of \$50,000,000,000. Out of the \$42,000,000,000 we have previously seen that about \$7,900,000,000 was taken out by the persons receiving more than \$3000 net income per annum, and about \$2,100,000,000 was retained by corporations. So far our feet have kept on pretty firm ground.

I am now obliged to enter a rather shadowy vale. The

wage-earners will probably disclaim the men earning \$3000 per annum as being any of them, and we have seen from the income-tax returns that the number of wage-earners who appeared in the tax-gatherer's list was insignificant. Where, then, shall we draw the line between salaried men and wage-earners, pure and simple? There can be no sharp line. I shall not, however, violate common sense if I draw an arbitrary line at \$2000. Even in 1916 there were many classes of mechanics, railway-men, printers, and others who received \$6 per day, and could work 300 days per year if they wanted to. Accepting this dividing line, it remains to segregate the share of persons earning from \$2000 to \$3000, and I am bound to say that I know of no good method for doing this. The Bankers Trust Company, in a pamphlet published in 1918, estimated 1,247,000 families receiving an aggregate of \$3,077,425,000 at the rate of \$2000 to \$3000 per year. Assuming this estimate to be carefully made, it is manifestly too large for my present purpose for it is computed on the basis of the family rather than the person, and undoubtedly includes farmers whom I have segregated. Moreover, this class of persons undoubtedly participated largely in the rents, interest, and dividends that were not received by the capitalistic class. This is, indeed, a zone of great uncertainty; one whereof the conditions cannot be deciphered with the aid of any existing data. In this zone the number of families and workers is probably more nearly coincident than in the class receiving incomes below \$2000. I am going to assume that the number of workers in the \$2000-\$3000 class was 1,250,000, and that they received \$3,000,000,000 in 1916 without duplicating anything else in these calculations.† In fact, the number of workers duplicates what will appear in a subsequent list aggregating 41,000,000, and the deduction of \$3,000,000,000 will duplicate to a more or less extent the deductions for agriculture, dividends, and interest in the next following table.

I may now usefully summarize this line of reasoning and deduction in a table as follows:

Total produce of the United States, 1916.....	\$50,000,000,000
Deduct net produce of agriculture.....	8,000,000,000
Total of all other produce.....	\$42,000,000,000
Deduct share of persons receiving plus \$3000.....	7,900,000,000
Total remaining.....	\$34,100,000,000
Deduct retention by corporations.....	2,100,000,000
Total remaining.....	\$32,000,000,000
Deduct share of \$2000-\$3000 class.....	3,000,000,000
Total remaining.....	\$29,000,000,000
Deduct dividends, etc., received by \$3000 class.....	1,000,000,000
Total for non-agricultural wage-earners.....	\$28,000,000,000

As previously pointed out, the sum retained by corporations will eventually go, to the extent of 44%, to the \$3000 class. My last deduction, \$1,000,000,000, is purely one of conjecture.

The foregoing computation is by no means to be accepted as precise. There was a considerable evasion of

income tax by persons just over the line, which has been established rather conclusively in a paper by Professor Friday on 'Statistics of Income' in the 'American Economic Review' of September 1919. Certain governmental officials were exempt from making returns. Finally, the interest on some Federal, State, and municipal bond issues was exempt in behalf of everybody. I believe, however, that my rough deductions for the \$3000 classes are sufficiently liberal to allow for all unreturned capitalistic income.

In this connection Professor Friday makes a significant statement that is in line with what has been pointed out herein respecting the division of dividends. He says: "I estimate that the total interest paid by corporations alone during 1916 was \$1,700,000,000. The total amount reported by people with incomes of \$3000 and over is \$667,566,376. We do not know how much of this interest comes from sources other than corporate securities, such as real estate mortgages, but after making some reasonable allowance for these it seems pretty evident that not more than 30 to 35% of the interest-bearing obligations of corporations are held by persons having incomes of \$3000, who reported to the Department of Internal Revenue in 1916."

It seems to me that this information is far more portentous than the above conclusion would indicate. If the interest paid by corporations was \$1,700,000,000, the total interest, including that on notes, mortgages, and Federal, State, and municipal bonds must have been far greater, and if what the people of plus \$3000 incomes received was only about 39% of the corporate interest it must have been a far smaller proportion of the total interest.

Let us now examine the number of workers, other than agriculturists, among whom \$28,000,000,000 was shared. With respect to the number of wage-earners in the United States in 1916, a year that is about midway between two census years, there are some conflicting estimates, all of them official. We have the U. S. Census of Manufactures in 1914 giving the number of factory workers in that year. Other governmental bureaus have given estimates for particular industries, year by year. The Public Service Reserve of the Department of Labor estimated the total labor-power (men and women) in the United States in 1917 at 40,100,000. The Provost Marshal General, on the basis of the figures of the first Selective Draft in 1917, estimated the total industrial population in 1917 at 43,282,911. In February 1919, a total of 43,206,912 was estimated.

An examination of the estimates for 1917, with the aid of collateral data, leads me to adopt the following figures as the most probable approximation of the labor power and its distribution among major occupations:

Farmers.....	7,000,000
Farm laborers.....	7,000,000
Lumbermen.....	200,000
Coal miners.....	750,000
Metal miners and quarrymen.....	200,000
Petroleum producers.....	50,000
General laborers.....	4,000,000
Builders.....	2,800,000
Factories.....	7,200,000
Transportation.....	2,800,000

†This estimate, rough though it be, finds strong support as to number in the income-tax returns for 1917, which show that 1,832,132 persons reported net income of \$2000 and over.

Trade	4 000 000
Public service	500 000
Private servants	4 000 000
Clerks, not elsewhere included	500 000
Total	41 000 000

This is an industrial classification rather than an occupational. Thus, the clerical class is distributed among the industries in which employed instead of being segregated as a class. Socially and economically, however, the position of the clerk is substantially the same, irrespective of the industry in which occupied. It will be noted, moreover, that throughout this study my thought has been directed to the division of the national income first between the directing and directed classes and next among the directed classes, that is, the great body of workers. My dividing line is purely the arbitrary line of a certain income. This makes no discrimination among those who work alone (for their own account) those who hire one or more helpers, and those who are hired (the proletariat). According to my view there is no economic difference between conditions of how work is done, but there may be distinct social difference. According to the socialistic view the proprietor of a boot-blackening chair, deriving a net annual revenue of \$800 from his business and employing a helper, is a member of the capitalistic class. I do not so regard him.

The total number of persons engaged in clerical work is given at 2,000,000 in one estimate, but that figure would manifestly duplicate persons entered under other classifications in the above table, and I have used the figure of 500,000 as a conjectural allowance for those not elsewhere included, arriving at an estimate of the total number of workers that is a little larger than that of the Department of Labor and a little smaller than that of the Provost Marshal General.

From the total of 41,000,000 workers I deduct the 14,000,000 agriculturists, whose position is considered separately. I might with some reason also exclude the persons in public service who do not produce and the domestic servants who are direct producers to only a partial extent and whose remuneration comes largely out of the income of persons receiving upward of \$3000 per annum. However, the service classes, public and private, have to participate in the division of national income, and, except those who minister solely to purposes of vicious and wasteful pleasure, they are indirectly producers through promoting the efficiency of the direct. Consequently it may be said that the non-agricultural dividend of \$28,000,000,000 in 1916 was shared by 27,000,000 wage-earners, the quotient being about \$1040 per person.

The actual average receipt may have been even larger than that for two major reasons, namely: (1) A significant part of what is enumerated as the industrial population is habitually idle, from choice, either a part of the men or all of it. (2) The large class of men, amounting nearly 10% of the whole, that is engaged in domestic and manual service, and a much larger proportion of the women, receive a large part of their remuneration in the form of board and lodging, which is paid mainly, if not wholly, by the classes enjoying incomes in excess of \$2000. It would be an extraordinarily valuable thing if we

could analyze the receipts of labor according to major groups. Unfortunately, there does not exist sufficient data to permit that to be done with anything like completeness. Nevertheless, with the aid of such figures as are available, plus some imagination and conjecture, we may be able to discern the broad outlines of the structure.

According to the U. S. Department of Agriculture, 61.9% of the farm labor is hired "with board" and 38.1% "without board". The average wage in the whole country "with board" in 1916 was \$23.25 per month; "without board" it was \$32.83. These are arithmetic averages by States, not weighted averages taking into account the relative number of men employed in the several States; nor is there any cognizance taken of the lost time by the laborers employed by the day. However, we may deduce the rough idea that the average income of the farm laborer in 1916 was something like 12 by \$32.83, or \$394, say, \$400, approximately, which by the majority was received partly in money and partly in goods (board). The actual income of this class of workers, which is subject to a great deal of lost time, owing to the seasonal character of its occupation, was probably materially less than that. This is the largest class of workers, numbering about 7,000,000, and is the most poorly paid. If this class received \$2,800,000,000 in the aggregate, the 7,000,000 farmers must have got about \$5,200,000,000, or an average of about \$743 each.

Coal mining is divided into anthracite and bituminous, in which important differences of conditions exist. Unfortunately, I have been unable to find comprehensive statistics of wages in either of these industries in 1916. In connection with the settlement of the bituminous strike in the latter part of 1919 the following statement was issued officially from Washington:

The table below, compiled from data furnished by the Federal Trade Commission, shows the average earnings of mine-workers in the central competitive fields during 1918. This table covers a tonnage for the year of 148,393,227, or 56% of the total production of the central competitive fields and nearly one-third of the total normal production of the entire country.

Tonnage	148,393,227
Labor cost	\$197,160,499
Average number of operators	385.8
Average days worked	250.8
Average days worked per month	20.9
Average number of miners per month	68,599.4
Average number of other employees per month	58,554.8
Average number of all employees per month	127,154.2
Total days worked, miners	17,204,729.5
Total days worked, all employees	31,890,273.4
Average tons per day worked, miners	8.63
Average tons per day worked, all employees	4.65
Average pay per day, all employees	\$6.18
Average pay per period, all employees	\$1550.56
Average labor cost per ton	\$1.33

It is to be noted clearly that the above data are for 1918, not 1916. Dr. Garfield computed the advance in wages from 1914 to 1919 as having been in the ratio of 100:157.6. This would indicate that the average earnings of a great group of the bituminous coal miners, approximately one-third of the total number, were at least \$1000 in 1916.

Metal mining, which employed 200,000 men in 1916 (including quarrymen), is a well-paid vocation. In 1916

miners received \$3 to \$5 per day and were able to work full time. Metal mining is a well-organized industry, in which operations are conducted on a large scale, continuity of work being one of the elements of success. Mines and mills are commonly operated from 300 to 310 days of the year. There are no statistics available respecting the total earnings of metal miners in 1916, but there is much illuminating data.

The most highly paid among the metal miners are those engaged in copper mining in the Rocky Mountain region. In 1916-'17 the Anaconda Copper Mining Co. paid \$17,027,720 to 11,442 miners, an average of \$1488 per man. The Butte scale determines not only the wages throughout Montana, but also those in the Coeur d'Alene silver-lead district, while throughout the copper districts of Arizona the rates conform closely to it. About the lowest rate of wages in metal mining obtains in the lead mines of southwestern Missouri, where the base rate in 1916 was \$2.80 per day in February, rising to \$3.10 in November. There can be no doubt about metal mining being one of the more lucrative of the major industries, and I conjecture that the average per man in 1916 was fully \$1250.

This is one of the most illuminating revelations of this statistical study. If we exclude quarrymen and miners of miscellaneous substances, we should find that the great metal-mining industry of the United States is conducted by about 150,000 men, producing about 150,000,000 tons of crude ore per annum. Such a performance has been rendered possible only by the mind of engineers and the resources of capital backing them, which have reduced the requirements for manual labor. That the men working in the mines have participated in the benefits is seen from the fact that in 1916 they received an average wage of \$1250 (probably), while the railway-man got only \$886, the factory worker \$675, and the agricultural laborer \$400. If the farm could be so mechanized as the mine, and if farming could be conducted by great corporations, able to employ talent, there can be no doubt that the number of agricultural workers would be reduced and the average earnings per man would be increased.

Smelters also are well-paid workmen. The Anaconda Copper Mining Co. in 1916-'17 paid its 4793 men at Anaconda and Great Falls a total of \$8,558,793.57, an average of about \$1800 per man. The American Smelting & Refining Co., however, whose operations are mainly in manufacturing districts rather than mining, paid its 21,073 employees in 1916 an average of only \$809.

In the iron and steel industry we find precise figures of earnings in the reports of the big companies. The United States Steel Corporation, Midvale, Republic, and Bethlehem in 1916 paid \$359,185,642 in wages to 343,785 persons, an average of \$1045 per person. This is not exactly an indication of the earnings of iron and steel workers, for the employees of these companies include miners, coke makers, railwaymen, etc.

Respecting the position of the factory workers we may get some indices from the United States Census of Manufactures in 1914. For that year there was reported a total of 7,036,337 wage-earners, male and female, employed on the average, who received an aggregate of

\$4,078,332,000 in wages, or about \$580 per person. The highest paid were the machinists—the makers of vehicles—who got about \$750. Railway shopmen got about \$700 and persons engaged in the iron and steel industry received about the same figure. The lowest paid were the textile workers, clothing makers, and tobacco workers, who got only \$440 to \$450. These lowly paid industries employed the largest proportion of women. In the more highly paid industries, involving heavy work, the percentage of women was least.

These figures do not agree very well with those of the United States Steel Corporation, which, in 1914, employed 179,353 persons and paid them an average of \$905. This company's average payment increased to \$1042 in 1916. If the wages of all the factory workers of the country increased in the same ratio, a not unreasonable assumption, considering its moderate character, their average earning in 1916 was something like \$668 compared with the average of \$580 in 1914. The Department of Labor of the State of New York, which obtains direct reports of wages paid, number of employees, etc., in a large number of factories in that State, estimates (in a private communication to me by L. W. Hatch, chief statistician) that total wages of \$826,665,000 were paid in 1916 to 1,206,000 employees, an average of about \$685 per person. This agrees closely with my estimate of \$668 based on the census figures for 1914. It is rational to estimate that the factory workers of the United States received an average of \$675 in 1916.

According to the statistics of the Interstate Commerce Commission 1,700,814 railway employees in 1916 received \$1,506,960,995, giving them an average of \$886 per person.

Professional service, according to the Provost Marshal, occupied about 2,200,000 men. Figures issued by the same authority in February 1919, put professional service at 1,912,093 and clerical occupation at 1,938,906. It is uncertain just what these groups do or do not include. According to the income tax returns for 1916 the number of purely professional men who received taxable incomes was about 70,000. I cannot make any sure deductions from the figures that are available. It looks as though there might be somewhere from 2,000,000 to 3,800,000 men engaged in clerical work and the lower ranks of professional service. These men receive incomes ranging from \$3000 per annum down to \$500, with an average that is probably higher than those of any of the major classes of manual workers.

BORAX is a valuable flux for chemical and metallurgical purposes. It is used in the manufacture of pottery-glazes and enamels, and as a glaze for paper and linen. It is also used in tanning and glue manufacture. Its property of adhering closely to clean surfaces of metal under high temperature and preventing oxidation causes it to be largely employed in brazing and as a flux in brass manufacture. It is also used in the manufacture of soap and glass, and in numerous other ways. As an antiseptic it is used as medicine, and as a food preservative. Borate of chromium is used as a pigment in calico printing.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

FIRST SHIPMENT FROM THE NEW MILL AT THE KINGMAN CONSOLIDATED.

PRESCOTT-JEROME DISTRICT.—Ben Rybon, president of the Silver Belt Consolidated Mining Co., has announced that financial arrangements are complete and operations at the mine which is located half way between Humboldt and McCabe, will be commenced immediately. Twenty-five years ago this mine produced over \$1,000,000 in silver. It is said that there are 17,000 tons of ore on the dump and 25,000 tons in the stopes that will average 20 oz. to the ton in silver. It is planned to build a mill and sink the shaft to the 300-ft. level. It is reported that the Shannon Copper Co. is still carrying on development at the Yeager Canyon property and that some ore is being shipped from the company's mine at Gleeson.

Sinking of the Dundee-Arizona shaft, it is reported, will probably be resumed in the near future. Through the efforts of the pumps the water has finally been lowered to the bottom of the shaft, approximately 820 ft. below the collar. Plans are under way to put on three shifts in the shaft and continue sinking to the 900 or 950-ft. level before cutting another station. The new reverberatory furnaces at the United Verde Extension were tried out during the month of August; with the operation of both the reverberatory and blast-furnaces, the total production for this month was approximately 5,000,000 lb. of copper. The average tenor of the ore was 14%.

KINGMAN.—The Walnut Creek Mining Co. has taken over the Harrison group of claims in the Secret Pass district. Grading for the shaft site, head-frame, and hoist is completed. The Harrison group of mines has had some development which has exposed several veins of high-grade silver ore. It is the intention of the new company to sink the shaft several hundred feet. Jack Zwinge is in charge of the work. Contractors are now at work in the shaft of the Old Dad Mining Co. which is being re-financed. The shaft has reached a depth of 10 ft. and exposed a 3-ft. vein. The new electrical machinery has been installed at the I. X. L. mine and sinking below the 265-ft. level is under way. It is the intention to sink to the 500-ft. level at which point lateral development will be commenced. The first carload of concentrate from the new mill of the Kingman Consolidated Mining Co. has been shipped. The company is also shipping high-grade ore obtained from leases. The main tunnel is being driven rapidly, all new machinery now being in place. William Halloran is in charge. The Cyclopic mine has

just made an \$800 gold-bullion clean-up from the first run of the new mill. Recent development to the northwest, it is reported, has opened a large body of \$12 ore. F. Humphrey is superintendent.

BISBEE-WARREN DISTRICT.—Smelter production of the Phelps Dodge Corporation in September was 7,998,000 lb. of copper, compared with 15,500,623 lb. in September 1918. Copper production by Calumet & Arizona in September was 3,038,000 lb., compared with 4,868,000 lb. in 1918. The Shattuck-Arizona company's output for September was 166,513 lb. copper, 921,912 lb. lead, 57,008 oz. silver, and 524 oz. gold.

According to the Arizona State mine inspector, Arizona mines are now employing about 60% of the normal number of men. There are now engaged in and around the mines and mills approximately 20,000 men as compared with more than 30,000 during normal times. One of the large copper-producing companies is reported to be now handling about 130,000 tons of ore per month through its reduction plant as compared to 300,000 tons per month during the peak of production during the War. Other large companies are said to be handling from 40 to 75% of their normal capacities. The U. S. Geological Survey in co-operation with the Arizona State Bureau of Mines, under the direction of G. M. Butler of Tucson, director of the State bureau, has recently prepared a detailed map of the State of Arizona. The map is on a scale of eight miles to the inch and gives valuable geographical as well as geological and mineral data.

VERDE VALLEY.—One of the interesting engineering projects which will be undertaken in Arizona in the near future is the construction of an impounding dam at the Box Canyon, nine miles below Camp Verde, and which it is said may be started as early as next January. The proposed dam will impound water for the irrigation of 90,000 acres of fertile land in the Paradise valley, northeast of Phoenix. It is estimated that the dam will take from two to three years to complete, and next to Lake Roosevelt the reservoir will be the largest artificial lake in Arizona.

AJO.—The September output of the New Cornelia Copper Co. was 3,314,000 lb. Through a judgment of the U. S. court of appeals at San Francisco, reversing a verdict of the federal court at Tucson, the New Cornelia Copper Co. is finally victor in one of the oddest lawsuits known in mining litigation. On November 27, 1918, a number of Mexican employees of the corporation built a fire to warm themselves while waiting for the time to go

to work. The fire was lighted against an old boiler, property of the company, but for some time unused. In the boiler was a quantity of dynamite stolen from the company, and hidden there by the thieves. There was an explosion of the powder with injury to some of the men. The widow of Jesus Maria Ochoa, killed, sued for damages, after refusing an offer of settlement by the company, which, however, at no time assumed any degree of responsibility. She was given \$10,000 in the lower court, but the appellate court failed to find that responsibility attached to the defendant, and reversed the decision.

GLOBE.—The disseminated orebody on the Castle Dome has been prospected by diamond-drill borings for a length of more than 3000 ft., and shows an average copper content of 1.4%. A capping, 20 ft. thick, is estimated to contain 1,000,000 tons of ore of the same character carrying 2½% copper. At the Superior and Boston a force of 125 men is employed on development and extraction of ore, which is shipped to the El Paso smelter, and the International at Miami.

CLIFTON-MORENCI DISTRICT.—The Morenci branch of the Phelps Dodge Corporation is still further curtailing its prospect and development work. It is over a year since this company ceased production and was put on a purely development basis. During this period the mill and smelter have both been closed down. Incidentally, plans have been under way regarding a consolidation of this company's property with that of the Arizona Copper Co., which has extensive ore-reserves, but as yet nothing definite has materialized. The working force of the Morenci branch of the Phelps Dodge Corporation has been cut to about one-third of its former number.

COLORADO

THE COLORADO CONSOLIDATED INCREASES THE CAPACITY OF ITS MILL.

CRIPPLE CREEK.—Drilling has reached 1300 ft. depth in the formation test, the core showing granite with slight fracture. The drillers are making about 20 ft. daily. The district mines report serious labor shortage with more miners leaving the district than returning, a condition not expected after the harvest season.

IDAHO SPRINGS.—The unwatering of the Little Mattie shaft by the recently organized Commonwealth Silver Mines, Inc., is progressing. The mine and mill are being electrically equipped and heavy production will follow. The Golden Edge property, controlled by this new company, has ore of smelting and milling-grade exposed in both shaft and tunnel workings. The mill at the Reynolds property at Alice is to be enlarged to handle ores from the Reynolds and Meteor mines.

SILVERTON.—Albert Kolz, former superintendent, has leased the Hamlet and is adding a flotation-unit to the mill and erecting a tram for the transportation of ore from the tunnel mouth to the mill. The ore carries silver, lead, and copper ranging in value from \$20 to \$100 per ton. The property has been idle a long time. Magnet lessees are mining ore containing gold, silver, and lead

and are preparing a shipment for the smelter. During September, 76 cars of ore were shipped from Silverton mines, the Sunnyside leading with 42 cars.

LAKE CITY.—The Home Mining Co. is constructing an ore-house and blacksmith shop at the Little Chief, adjoining the Pelican, a steady producer of the Lake City district.

The Colorado Consolidated Mines & Power Co. is increasing the capacity of its plant at Sherman; the mill is being changed from chlorination to concentration with a flotation-unit.

MICHIGAN

COAL SUPPLIES AMPLE FOR THE WINTER.

HOUGHTON.—Superior Copper is about to suspend, temporarily at least, until costs get to lower levels. High freight-rates are largely responsible for the suspension, because all material must be transported over the Mineral Range railroad. For the past four or five months, Superior has been shipping about 2000 tons per month, practically all of which came from the 31st level, north and south of the shaft, and cross-cuts across the formation where copper-bearing 'rock' was sought, both in the Superior and West lodes. It had been proposed also to extend the 33rd level drift both north and south from the 31st level winze in the hope of opening ground that would yield a profit.

Prevailing high prices for supplies and labor, coupled with scarcity of labor, has resulted in temporary suspension of operations at the Michigan mine. There is little likelihood that the property will be re-opened until there is a decided change in conditions. Physically the mine is in splendid shape. The openings on the 4th, 5th, 6th, and 7th levels have disclosed encouraging ground on the Butler vein, while the openings on the Omega and Evergreen lodes are promising. An important feature is the unusual width of the Butler, which is 30 to 80 ft. Ordinarily a lode rarely exceeds 40 ft. at the outside and there are mines on the Lake that consider 20 ft. wholly sufficient. With the small force that has been employed for the last six months, Michigan has been producing from 110,000 to 180,000 lb. per month. Under favorable conditions it is believed the output could be easily doubled.

The Lake copper mines now have coal enough on hand for about 60% of their needs for the winter on the present operating basis, which is about 60% of normal. Coal shipments have been coming in at the rate of approximately 140,000 tons per month for the last two months, and if this rate is continued until December 1 the coal supplies for the mines, mills, and smelters will be ample. The advance in freight-rates has been a serious proposition for local mines that do not own their own railroads and it is one that is far from solved. Calumet & Hecla, owning its own line, is not affected, but some of its subsidiaries, including Ahmeek, Osceola, and Superior, are hard hit. Under existing rates it is costing Ahmeek \$14.50 for each car of 'rock' that is hauled over the Mineral Range railroad, or approximately \$700 per day,

The freight on coal is \$22 per car and this item alone represents upward of \$2500 per month. The rate on Allouez rock is the same as Ahmeek's, and as soon as the mine resumes work on the old schedule of operations its cost for hauling rock will be about \$400 per day. North Kearsarge No. 4 shaft is in the same class, while the shafts to the south are in a different one and accordingly their rate is slightly lower. Centennial, when operating at capacity, also will have to pay a large freight bill, both for ore haulage and coal transportation. The Calumet & Hecla has had under consideration the building of a railroad between Lake Linden and the Ahmeek mine to serve its subsidiaries, but no definite conclusion has yet been reached. A preliminary survey of the 7-mile route was made several years ago.

September shipments of copper, by boat, including

conglomerate, one has been sent to Ahmeek, where it is operating with splendid results. Unlike some of the models that were introduced two or three years ago, the new scrapers are comparatively light in construction and can be employed in any stope. The principal drawback of the shovels used in some of the other mines was the size and weight.

Mayflower-Old Colony has encountered some highly mineralized ground about 200 ft. from the shaft in the south drift. It is regular amygdaloid material, containing small bits of copper not unlike that in the vein when it was first opened on the 1700-ft. level. The most encouraging feature of the operations in the south drift, however, is the indication that the formation is becoming regular. There is a likelihood that the disturbed zone has disappeared. Wolverine soon will begin to blast out

LEAD SMELTER OF THE CIA. METALURGICA, SAN LUIS POTOSI, MEXICO

about 1000 tons that went from the Calumet & Hecla smelters to France, totaled 7,274,000 lb. This compares with 16,860,000 lb. in August and slightly over 10,000,000 lb. in July. The shipments this summer, exclusive of small quantities that went out by rail, totaled 44,834,000 lb., considerably less than was produced during the same period. Tonnage records for the Calumet & Hecla subsidiaries reflect a decrease in the output of the old Osceola, which reported 4650 tons for the month. This is due to the recent reduction in the working forces, incident to the operation of the mine on the one-shift basis. The North Kearsarge branch of Osceola, however, is holding well up to the normal of the year with 37,500 tons for the month. Ahmeek's production for the month was the most promising of any of the Calumet group, for 72,050 tons was shipped. On a yield of 22 lb. per ton this means a refined copper product of 1,607,000 lb., the equal of the August record.

It will be late spring before the Calumet & Hecla has a sufficient number of underground scrapers in operation to make any material difference in output, but the work of constructing them will be started at once. In addition to three or four models in use in the parent mine, in the

the concrete dividers and stringers from the 32nd to the 35th level, because of the fact that the pillars have been moving and crushing, just as occurred from the 27th to the 29th level in No. 4 shaft. Operations at Wolverine still consist in widening out stopes and drifts, cutting out vein-matter along the foot-wall in recent and older workings, and regular stoping north and south of both shafts. The cutting-out process netted more than 30% of the ore shipped to the mill last year and this work promises to yield equally as much during the present year. Like Mohawk, Wolverine could use many more miners and trammers. The production of each is 50% of normal. Ultimately Mohawk will have mastered the trammer problem by the use of the stope scraper, mechanical and rope haulage, and a level-scraper. It is proposed to install stope scrapers in Mohawk as soon as the price of material drops. As long as the metal market holds around present levels, there will be no special effort to increase the output of either mine. Mohawk's openings are as extensive, if not greater, than a year ago at this time, while Wolverine during the past six months has prepared to cut out the vein from surface to the 19th level.

NEVADA

CONSOLIDATED VIRGINIA WILL RE-OPEN THE 2250-FT. LEVEL.

DIVIDE.—The presence of Jackling-Hayden, Stone & Co. engineers lends color to the report that Easterners are heavily interested in the Tonopah Divide and that the mine will be re-sampled for them. H. C. Brougher, president of the company, also is at Tonopah. The Tonopah Divide will stop shipping to the MacNamara mill on November 1 and from that date the ore will be sent to the Belmont mill, where it will be treated at a lower rate than is charged at the MacNamara. After November 1 shipments will be made at a rate of 50 tons daily, or 15 tons more than the present rate. The cross-cuts on the 800 and 1000-ft. levels are now within 50 ft. of the vein.

TOLICHA.—The Loring interests have taken an option on the Landmark group of three claims, owned by Thomas A. Harney, Edward S. Harney, Edward Yeiser, Nick Ableman, Edward Ashton, and others. Neither the terms of the option nor the purchase price have been announced. The closing of the deal ends negotiations of several months and it is reported that the holders of the option have secured full control, with the right to do whatever work is considered advisable. Charles D. Wilkinson, engineer for Loring, has completed a second sampling of the claims. Tolicha is 45 miles south-east of Goldfield, the nearest important town, and is 12 miles from the Tonopah & Tidewater railroad. The claims contain seven veins, three of which have been prospected at a depth of 50 ft. by a tunnel. Reports of remarkable widths of high-grade gold ore in the Landmark group frequently have come from the district.

VIRGINIA CITY.—Driving of the tunnel of the United Comstock has been started from the portal on American Flat and it will be continued by three shifts. The company is reaching through several shafts other places from which the tunnel will be driven. The Consolidated Virginia has started to re-open the 2250-ft. level to prospect for the extension of the ore-shoot now being mined through a winze from the 2150-ft. level. A drift from this winze continues to open ore.

BARCELONA.—In the fourth annual report of the company, Jules V. Barnd, president of the Spanish Belt, says that the building and the foundations for the machinery for the 50-ton mill have been completed and that the machinery will be moved to the mine in the very near future. The plant will have 10 stamps and concentration and flotation will be used. The ore contains silver and lead and it is estimated that the extraction will be 90%. There is 75,000 tons of 'probable ore' in the mine, assaying \$20 to \$30 per ton, according to the report. The company plans to ship the concentrate by auto 60 miles to the Tybo smelter.

MONTUZUMA, ESMERALDA COUNTY.—Edwin S. Giles of Goldfield has been employed as manager for the Montezuma Silver Mines Corporation, succeeding Arthur H. Cooper. The mine has been practically closed but the 240-ft. Caracas shaft, in which no work had been done for 45 years, is being re-timbered as the first work under

the new management. Work at the Arizona shaft will not be resumed for several months. The Montezuma is an old silver-lead producer. The 305-ft. Arizona shaft was sunk in recent years, but all of the late work has failed to open an orebody. Several months ago the company shipped a carload of ore, but the return was much lower than had been expected.

HAWTHORNE.—Work in the Lucky Boy, west of here, is to be resumed. This will be the first real effort in 10 years to develop the mine. Little, except the re-timbering for 350 ft. of the 6500-ft. drainage tunnel, has been done by the company since 1915. This tunnel is connected by a raise with the 700-ft. Hubbard lease shaft and it will be in the vicinity of this shaft that the first mining will be done. The Hubbard was a bonanza lease in the early days, but sinking of the shaft was stopped when the water-level was reached at 700 ft. The drainage tunnel reaches a depth of more than 1000 feet.

RENO.—Complete electric equipment is being put in place at the Black Panther, a copper-silver-gold mine three miles north of here, and when this has been completed the shaft, now 200 ft. deep, will be continued to 500, with stations for lateral work at 100-ft. intervals. A four-mile electric-power line is being constructed to the mine.

ARROWHEAD.—A 35-hp. gasoline hoist and a 40-ft. steel head-frame have been bought by the Arrowhead for use in sinking the shaft 100 or 200 ft. from the present depth of 265 ft. Shipments of \$150 to \$200 ore continue to be made to Tonopah. There is in the bottom of the shaft 18 in. of \$170 ore. Mark G. Bradshaw is now consulting engineer.

ROUND MOUNTAIN.—Shortage of water again retarded the operations of the Round Mountain in the placer field during the season this year and lode mining has been discontinued by the company because of the high cost of supplies. However, the lode mine is being developed on a good scale by lessees and to September 1 it had produced \$40,000. The placer mine produced \$53,000 to September 1. The Fairview mill produced \$99,500 gross, \$34,000 net, to September 1.

ROCHESTER.—On application of a Lovelock mercantile company, a receiver has been appointed for the Nevada Packard Mines Co. The indebtedness is \$53,000. The application for a receiver, a friendly proceeding, was made after the mine and mill had been closed for two months because of lack of power due to low water in the Lahontan dam at Fallon. During this period the capacity of the mill was increased from 150 to 225 tons daily and improvements were made in the mine. The receiver, Herman Davis, formerly superintendent, expects to resume work before November 1.

PIOCHE.—A meeting of mining men in this district was called on October 9 to discuss the effect of the increase in freight-rates on the mineral industry of this district. The meeting was largely attended. For a number of years past, the Pioche district has supplied the Salt Lake Route with approximately 400 to 500 tons of ore per day

for shipment to Utah smelters, and unless a lower freight-rate is granted, there will be a continuation of the decrease in shipments, which is already noticeable. A number of constructive suggestions and inquiries were brought up at the meeting, among which was the building of a sampling-mill at Pioche and the mechanical mixing of the ores to take every possible advantage of the existing rates, and also the pooling of ore tonnage on contracts. Shipments are nearly 50% below normal as a result of the increased freight-rates. During the week ending October 9, the Prince Consolidated shipped 950 tons; Virginia Louise, 400; Bristol Silver Mines, 150; Black Metals, 110; Emerick-Deerfoot Lease, 85; Combined Metals, 50; S. T. Campbell, 50; making a total of 1795 tons.

MARBLE.—The Rural Mines, Inc., which has been operating extensively in Mohave county, Arizona, is now opening up the old Lodi mine. The mill has been over-

UTAH

NEW HOISTING-EQUIPMENT AT THE LEHI-TINTIC AND TINTIC PAYMASTER.

SALT LAKE CITY.—About two months ago, fire broke out in Sunnyside mine No. 2 of the Utah Fuel Co. at Sunnyside, and rescue-car No. 11 of the U. S. Bureau of Mines has been there continuously to assist in fighting the fire. The mine is now being opened, and G. C. McElroy, the engineer in charge of the car, is on the ground to take personal charge of the work and make investigations for the Bureau. During the week ending October 9, the Murray sampler of the Utah Ore Sampling Co. released 73 cars of ore from Utah mines, 11 from Nevada, 2 from California, 1 from Colorado, and 1 from Montana. The Tintic sampler of the same company released 35 cars of ore from Utah mines.

LOGAN.—A large body of magnesite ore is being de-

KENNEDY MINE, AMADOR COUNTY, CALIFORNIA

hailed, and necessary changes made, under the direction of G. E. Bateman and T. D. Walsh. It is the intention of the management to start milling operations before November 1. At present the ore-reserves are sufficient to supply the mill for two years, but development will nevertheless be continued actively. The present mill has a capacity of 25 tons per day; as soon as the proper flow-sheet has been determined, another milling unit, doubling the present capacity will be added.

EUREKA.—For the week ending October 9, the following shipments of ore and speiss, in transit to the Utah smelters, for reduction, went out over the Eureka-Nevada railway to Palisade, the cars carrying approximately ten tons each: from Eureka-Holly mine, 13 cars of ore; Cyanide mine, 3; Eureka-Croesus, 6; Eureka Prince, 5; from the old Silver West smelter dump, 3 cars of speiss; Eureka Consolidated smelter dump, 29 cars.

ADAMS HILL.—The Fraser brothers have finished several hundred dollars worth of work, cleaning out adits, drifts, etc., in advance of more important work planned for development in the near future, on the Altoona, Mohawk, and Loudown mines on Adams Hill, which have yielded large quantities of highly silicious ores that have assayed in carload lots up to and beyond \$100 per ton.

veloped in the Wasatch mountains, about 6 miles northeast of this city, according to Otto Hudson, who is operating the property. The initial shipment was made recently. This is the first magnesium carbonate to be discovered in Utah, and only two other States—California and Washington—are producing this kind of ore. It is reported that the deposit is 250 ft. thick and 1500 ft. long, and Mr. Hudson states that extensive operations are contemplated.

ALTA.—The Prince Alta Mining Co. has begun suit in the Third District Court at Salt Lake City against the Alta Consolidated Mining Co. to recover for 6000 tons of ore, valued at \$360,000, alleged to have been unlawfully and secretly extracted from the property of the plaintiff company. It is alleged that secret extraction of ore from the Christina Johnson claim began January 1, 1917, and that the ore was taken out through the workings of the defendant company. The plaintiff asks that judgment for damages in three times the amount of the actual value of the ore be allowed and that an injunction be issued against further working of the property in litigation.

BINGHAM.—The directors of the Utah-Apex Mining Co. have declared a dividend of 25c. per share, payable No-

vember 1. This will call for the payment of \$132,050 and will bring the grand total up to \$1,254,475. This is the first dividend disbursement in two years. Federal Judge Tillman D. Johnson has not yet announced a decision in the case of the Utah Apex Co. v. the Utah Consolidated Co., which was heard in Salt Lake City last spring. The company is now sinking a shaft to the 2000-ft. level, where the downward extension of the orebody now being mined on the 1800-ft. level will be opened. In addition to straight smelting-ore, the company is producing a quantity of low-grade ore, which is being handled in its mill, and the silver-lead concentrate is shipped to the Murray smelter. Like all other mining companies in this district, the Utah-Apex is short of skilled miners and could use 100 additional men. About 250 men are now employed by the company. During the first seven months of the current year, the Bingham Mines Co. and its subsidiaries earned \$238,149 after taxes, depletion, and depreciation, or the equivalent of \$1.59 per share. Net quick assets on August 7 were \$446,959, or approximately \$3 per share, most of which was cash and demand loans.

EUREKA.—During the week ended October 9, the mines in this district shipped a total of 142 cars of ore. The Chief Consolidated shipped 37; Tintic Standard, 27; Mammoth, 26; Dragon, 11; Eagle & Blue Bell, 8; Iron Blossom, 6; Victoria, 5; Iron King, 5; Swansea, 3; Gold Chain, 3; Gemini, 2; Blue Bell, 2; Grand Central, 2; Eureka Hill, 1; Centennial-Eureka, 1; Yankee, 1; Griggs-Huish, 1; and Ridge & Valley, 1. A contract for 100 ft. of sinking in the shaft at the Central Standard property has been awarded, according to John W. Taylor, who is in charge of the property. The shaft now has a depth of 575 ft. and the sinking is costing the company about \$30 per foot. During the last 100 ft. the shaft has been in solid limestone, which now shows considerable iron. J. Will Knight and Thomas Pierpont, of Provo, and their associates, control this property. At the Copper Leaf property, which is also under Mr. Taylor's supervision, several hundred feet of drifting has been done on the 100-ft. level. The drift is now being pushed to the north-west, and the face is about 1100 ft. from the shaft. Work is to be resumed at the property of the Tintic-Delaware Mining Co. in the western part of this district, according to John F. Rawson, former secretary-treasurer of the company. About two years ago, disagreement among the directors resulted in the suspension of operations. The company is one of the promising and well-known properties in the western part of the camp, and it is reported that there is a considerable quantity of ore averaging 12½% lead developed in the mine. Streaks of ore averaging from 30 to 70% lead, with 5 to 70 oz. in silver per ton, have been found in various winzes. The company is planning to resume both sinking and drifting. The new hoisting equipment at the property of the Lehi-Tintic Mining Co. has been received and erected. It is capable of handling shaft-work for a depth of 1000 ft. Charles Zabriskie, who is in charge of the property, stated that a shaft will be sunk 400 or 500 ft. from the lower

tunnel-level. H. G. Snyder, manager for the Tintic-Paymaster Mining Co., reports that an electric hoist, with a capacity of 1200 ft., has been installed and sinking commenced. About October 1, the work of cutting a station on the 375-ft. level was completed, and vigorous development will be carried on during the coming winter. At a meeting of the directors of the Chief Consolidated Mining Co. on October 15, a quarterly dividend of 10c. per share was declared, payable November 1. This will call for the payment of \$88,423, and will bring the grand total of such disbursements up to \$1,871,517.

PARK CITY.—Seven mines in this district shipped a total of 1707 tons of ore during the week ending October 8, of which the Judge M. & S. Co. produced 554; Silver King Coalition, 541; Ontario, 259; Daly-West, 117; Keystone, 83; and Naildriver, 60. A shipment of 40 tons of premium spelter was made by the Judge smelter. Work has been resumed on the 2000-ft. level at the Ontario mine, the deepest in the property. About a month ago, the breaking of a crank-shaft on the compressor caused suspension of work, with the result that the lower levels were flooded. A new pump has been installed, and the water has been pumped out. An exceptionally promising strike was reported to have been made on the 2000-ft. level at the time of the accident.

BIG COTTONWOOD CANYON.—Development work at the Big Cottonwood Coalition Mines Co. is approaching an interesting stage, according to C. E. Robertson, secretary-treasurer. The main working-adit, now in the formation over 3200 ft., is rapidly nearing its objective. The face, which is about 600 ft. from the Copper King fissure, is showing increasing mineralization. This company owns a total of 74 claims, adjoining the Woodlawn and Prince of Wales mines. Recently a survey of the property, both underground and surface, has been completed by Robert Gorlinski, the company's engineer, and all the claims relocated. During the past year the company acquired the old Copper King property, consisting of 23 claims. Conditions at the Cottonwood King property are promising, according to S. A. Parry. The Sunnyside fissure, which has been reached, shows several inches of lead-silver ore on the hanging-wall side and on the foot-wall side about 8 in. of the same kind of ore, which is in a decomposed blue limestone. The fissure, which is about 8 ft. wide and striking north-west, should intercept the Congor fissure in 20 to 25 ft. The working-face is a blue limestone and lime spar, showing seams of lead and silver with copper stain, and is considered favorable to the finding of ore.

BRITISH COLUMBIA

DEPLETION OF ORE-RESERVES MAY BE RECOGNIZED IN
TAXATION OF MINES.

HAZELTON.—The 1000-ft. tunnel at the Babine Bonanza has cut a 34-in. lode, 17 in. of which is high-grade, an average of 10 assays running \$236 per ton. The assays ranged from \$2 to \$20 in gold and 132 to 358 oz. in silver per ton, and from 3 to 7% copper, 3 to 19% lead, and 2 to 22% zinc. The remainder of the lode is milling-ore.

Another tunnel is to be started at a lower level, and arrangements have been made to continue the development throughout the winter. The Steamship Mining Co. has bonded the Paddy Higgings property, on Babine mountain, and has started to develop it by a tunnel. There is a good surface showing.

PRINCE RUPERT.—Diamond-drill exploration at the Spider group, Salmon River district, has been so satisfactory that the Algonican Development Co., which has a bond on the property, has established a permanent camp, and will continue development through the winter. Work at the Forty-Nine group, in the same district, has been suspended indefinitely. Officers of the company state that work will be re-started as soon as suitable roads have been made, but that under present conditions transportation charges are too high for profitable work. R. G. Leekie has let a contract for a tunnel and a shaft at the Hercules group, Salmon river, and work will be started at once. Assays from a new discovery on Glacier creek, Bear river, have given returns running between \$320 and \$400 per ton. A small consignment of high-grade ore from the Esperanza group, Alice Arm district, is awaiting shipment to the Tacoma smelter. The Moose mine and the Silver Tip Extension, in the same district, are said to be developing well. What is required at the present time for the development of the numerous small properties in the mining districts within easy reach of this city is a sampling works, where trial shipments of a few tons could be sent and accurate returns obtained.

GRAND FORKS.—The shaft at the Molly Gibson, at Paulson, is being deepened, and is being sunk on a 7-ft. vein, which assays \$80 per ton in gold and silver. A tunnel also has been started to connect with the deepened shaft. Philip B. Freeland, district mining engineer, visited the Gloucester group recently, where the government diamond-drill is in operation, and reports that satisfactory progress is being made. The drill is being used to explore a pyroxenite belt carrying chalcopyrite in bunches and veinlets, and in places the chalcopyrite has been found to contain from a trace up to 0.38 oz. of platinum.

CRANBROOK.—The Consolidated Mining & Smelting Co. has started preliminary work for a concentrating plant to treat its Sullivan mine ore on the site of the old smelter, at Marysville. It is understood that the experimental work that has been undertaken at Trail has been practically completed, and a satisfactory concentration process has been devised for the treatment of the ore. The first unit of the plant is to have a capacity of 2500 tons of ore per day. Up to now only grading work has been done.

SLOCAN CITY.—The long-lost vein at the Evening Star mine at last has been recovered. On the advice of F. J. Parker, formerly manager of the North Star mine, at Kimberley, who now is acting as consulting engineer to Hugh Sutherland, owner of the Evening Star, a cross-cut was driven from about the middle of the tunnel that had been driven in an effort to re-locate the lode, and in this cross-cut the vein was found. The vein where cut con-

tains the same rich streak that characterized it in the upper workings of the mine.

VICTORIA.—Representatives of the mining operators of British Columbia are anxious to induce the Provincial government to amend the Taxation Act in order that allowance may be made for the depletion of ore-reserves in mining property. As it now stands, anything that is allowed comes as a concession from the Minister of Finance after an investigation. The opinion among mining men is that the principle of allowance for depletion of ore-reserves should be recognized in arriving at

THE COBALT DISTRICT

the basis for the taxation of a producing mine. A delegation from mining companies interested in this Province recently met the Premier to discuss this and other phases of the Act. The hearing given them was sympathetic and they are confident that the desired amendments will be made at the next session of the legislature.

Instructions have been given the Provincial Mining Engineers to prepare to deliver a series of lectures at the different centres of their several districts during the winter, the idea being to give prospectors an opportunity to obtain the knowledge necessary to guide them in selecting prospecting-ground and to enable them to recognize valuable minerals. This policy follows a suggestion from the Prospectors' Protective Association. W. E. Cockfield

of the Geological Survey has returned from the Keno Hill district. He says that much development is being carried on by the Yukon Gold Co., one of the Guggenheim enterprises. The company expects to ship 3000 tons of ore this winter. The ore was high-grade silver-lead, running 200 oz. silver per ton and from 50 to 60% lead. The principal minerals were galena, siderite manganese, and occasionally freibergite. The gold content was small, not exceeding, as a rule, \$4 per ton. On the upper Stewart river there were some stamp-mills in operation, but little placer mining was being done. A gold-dredge had been in operation on Hightett creek during the summer. A shipment of ore from the Nettie L. ran \$290 in silver per ton, while other shipments have given returns of 21 oz. gold, 230 oz. silver, a considerable amount of lead, and a small amount of zinc.

A local syndicate has been developing a talc property on the Port Alberni line of the Canadian National railway. At the present time it is producing about two cars of talc per week.

TRAIL.—During the last nine days of September ore receipts at the Trail smelter, of the Consolidated Mining, Smelting & Power Co., aggregated 12,744 tons, bringing the total for the year at 251,735 tons. The Washington mine, of Sandon, is added to the list of shippers. Mines of the smelter company contributed 11,549 tons of the total, leaving 1195 to the credit of independent operators.

STEWART.—W. R. Tonkin, president of the Fish Creek Mining Co., is quoted as stating that seven years work on its property, west of Salmon river and on the American side of the Portland Canal area, has justified a continuance of work and that shipment of ore will commence as soon as transportation facilities are secured. The lodes are quartz fissures carrying silver and gold and it is proposed to build a concentrator. Mr. Tonkin declares that as large a tonnage of ore will be developed on the American side of Salmon river as within Canadian territory, affirming that it has been only because of the remarkable showing of the Premier mine that the adjoining section has not received the attention its merit deserves. About 600 ft. of diamond-drilling is to be done on the Titan group of claims on Fisher creek. This property possesses a well-defined quartz vein. The Riverside group also has been under development, 350 ft. of tunneling having been done with satisfactory results. At the Premier mine the concentrating-mill, which will have a capacity of 100 tons per day, is making good progress.

ONTARIO

M'INTYRE-PORCUPINE AND TEMISKAMING PURCHASE COAL MINES.

TORONTO.—Notwithstanding the issue of an Order in Council by the Ontario government on December 18, 1919, relieving the claims staked by returned soldiers from forfeiture for non-performance of assessment work until January 1, 1921, such claims have in several cases been thrown open by mining recorders and re-staked and assessment work done by other parties. The attention of

the Minister of Mines having been drawn to the matter, instructions have been issued to protect such claims and reinstate the original holders.

PORCUPINE.—An interim report issued by the Hollinger Consolidated for the period between January 1 and September 8 shows that, with fewer employees and a lower tonnage than last year, the profits of the company have nevertheless increased. The net profits were \$2,581,373 from the treatment of 1838 tons of ore, as compared with \$2,408,209 from 1902 tons of ore during the corresponding period of 1919. The average number of men employed was 1838, as against 1902. At the annual meeting of the McIntyre on October 7, R. J. Ennis, general manager, said that exploration of vein No. 7 had resulted in the discovery of an extensive orebody between the 1375-ft. and 1600-ft. levels, which had been penetrated at two points 900 ft. apart and was found to contain ore yielding from \$13 to \$14 per ton. It was described as being richer than vein No. 5, so far the chief source of McIntyre ore, which has yielded 900,000 tons averaging about \$10 per ton. The work of de-watering the Vipond-North Thompson property has been commenced. As soon as it has been effected it is planned to put down the shaft from the 600-ft. level to a depth of 1100 ft. and open up levels at every 100 ft. In the meantime there is sufficient ore on the 600-ft. and upper levels to keep the mill working at capacity. On the Miracle property, controlled by the Miller Independence interests of Boston Creek, the diamond-drill is reported to have passed through a 40-ft. body of \$11 ore.

COBALT.—Adolph Lewisohn, president of the Kerr Lake, stated in his report that, due to the gradual exhaustion of the ore-reserves, production had been considerably less than in the preceding year and the cost higher. The mine is now producing a relatively small amount of silver and no definite estimate can be made as to how long this will continue. The Mining Corporation, which holds a lease on the old Foster property and is getting out good ore, is undertaking further exploration work by diamond-drilling. The Penn-Canadian, formerly a producing mine, which has been closed since last summer, has been taken over on option by F. C. Sutherland & Co., of Toronto. It has a pile of about 200,000 tons of slime and sand and about 8000 tons of low-grade ore underground. The shareholders of the Temiskaming Mining Co. have approved of the company's joining the McIntyre-Porcupine Mines in the purchase of two coal properties in Alberta, one of which is to cost \$600,000 and the other \$1,500,000. The Temiskaming has a treasury surplus of about \$1,000,000, while the McIntyre's surplus amounts to \$1,500,000. The decision to enter the coal business on a big scale is an expression on the part of the stockholders of a bid for the perpetuation of the Temiskaming at the expense of present dividends.

A fourth vein has been found on the Kerr Lake mine, running parallel to the three high-grade veins reported last week. During the fiscal year ended August 31 the Kerr Lake produced 956,049 oz. of silver at an average cost of 56.04 cents.

THE MINING SUMMARY

CALIFORNIA

Amador County.—Unwatering of the Kennedy mine at Jackson is progressing rapidly. The water has been lowered below the 2800-ft. level. There was some delay during the past week, caused when one of the large water skips got caught in the shaft and tore out some of the timbers. The broken sets have been replaced and smaller skips are being used for bailing and will continue to be used until the large skip is altered to make its use safe. The shaft is reported to be in first-class condition.

Mono County.—Application has been filed by C. F. Wildasin of Bishop for 1 cu. ft. per second from the drainage water from the Mammoth mining tunnel for power purposes. Total amount of power to be developed is 73.8 hp.

Nevada County.—The Empire Co. is re-opening its Pennsylvania unit, the closing of which was brought about by the power shortage. Between thirty and forty men have been placed on shift during the last few days. According to the management, the allowance of power has not been increased, but it has been found practicable to utilize compressed air from the Empire, the two mines being united underground. The Idaho-Maryland mine has now been unwatered to the 1200-ft. level, a gain of 100 ft. having been made during the last few days despite the power shortage. The installation of an electric pump in the incline shaft branching from the 1000-ft. vertical shaft has been completed, and rapid advance in unwatering is anticipated.

Plumas County.—The Seneca Eureka mine, in the Seneca district, about five miles from Lake Almano in one direction and an equal distance from Butte Valley in another, is now being actively developed by its owner, C. D. Hazzard of Quincy. The property, which has been in the possession of Hazzard for over 28 years, and has already cost him about \$45,000 for development work, covers an area of ground approximately two miles in length and one mile in width.

San Bernardino County.—The Giant Ledge property at Ivanpah has been examined by the California & Arizona Copper Co. This is one of the old properties of the district. High-grade silver ore has been found in the Don Longo, shipments containing as much as 300 oz. per ton. The Nevada-California company has also found rich ore in its Carbonate mine.

Shasta County.—The Original Quartz Hill Mining Co. has brought suit in the United States Court in Sacramento against the Mammoth Copper Co. and its parent corporation, the United States Smelting, Refining & Mining Co., to recover \$150,000 on account of an alleged breach of contract. The Mammoth, which had for eight years treated ore at the Kennett smelter from the Quartz Hill, as flux principally, shut down its work in the Quartz Hill in March 1914. The Quartz Hill claims the contract did not expire until October 15, 1916. The suit was brought Tuesday, October 12, or just three days before the claim would have been outlawed by the statute of limitation. The Estabrook gold dredges near Trinity Center has shut down on account of the high cost of material and labor.

Sierra County.—Application has been filed by G. W. Peer and H. L. Berkey of Scales, for 60 cu. ft. per second from Canyon creek, for hydraulic placer-mining purposes. The

amount of water to be stored is 8212 cu. ft. Diversion works: Main canal 8.12 miles long. The project consists of seven storage reservoirs, final diversion to be from the lower reservoir of this group. Thomas and Leo Bessler are preparing to build a five-stamp mill on their property in Downieville. Power will be furnished by water from the Downieville Water Co.'s ditch. The pay-shoot at the Oro mine has widened and a tunnel has been driven to cut it at a lower level.

IDAHO

Coeur d'Alene.—The Sterling Silver Mining Co. reports that five men are employed at the mine. The lower tunnel has been extended 400 ft. and a drift on the No. 1 vein has been driven for 100 ft. showing gray copper. This will reach a point beneath the surface-showing in another 200 ft. The holdings of the company cover two silver-vein systems and both are to be explored during the winter. Lessees operating the Yankee Boy mine are shipping high-grade ore, some running 300 oz. silver per ton. The management of the Silver Dale and Big Hill, operating on the west fork of Big creek, states that development work will be resumed. A cross-cut tunnel is being driven to reach the orebody 700 ft. beneath the upper workings where 5 ft. of concentrating-ore was uncovered. The Liston property, now known as the First National, will soon be under active development. The lower cross-cut tunnel has been extended over 3000 ft. to reach the vein at a depth of 1000 feet.

Mullan.—Consolidation of three groups of mining claims located in the Mullan district, including the Lucky Boy, the Silver Star, and the Goldbar is to be effected, according to M. D. Needham of Wallace, one of the owners of the Lucky Boy. A crew will be put to work extending a tunnel to the Lucky Boy vein. Surveys are said to indicate that it will require 170 ft. of additional work to reach the Lucky Boy vein. This will give the workings a depth of 40 ft. "New faces of ore have been disclosed at several places near here," said Harry W. Ingalls, manager for the Copper King Mining & Smelting Co. "The Copper King has struck a body of ore 4 ft. wide. It was found on the new level, which is 200 ft. above the tunnel-level, and was reached by a cross-cut from the raise. No assay has been made, but the appearance of the ore suggests a content of 12% lead and 10 oz. silver per ton, and no zinc. The ground is not broken, as in places on the main tunnel-level. It is away from the fault and so solid that it is not necessary to use timber. About 200 ft. of work has been done on this level, the depth of which is 1500 ft." A contract has been awarded for sinking an additional 200 ft. of shaft in the Morning mine.

Wardner.—A find of large promise has been made on the property of the North Bunker Hill Mining Co., near here. The ore has been entered for 15 ft. without determining its extent. Its grade is low, running 6% lead and an ounce of silver per ton. According to reports the strike was made on the 500-ft. level. A cross-cut from the shaft was driven 300 ft. west, where it entered the vein, and the vein was followed by a drift for 130 ft. Neither wall is in sight at the face of the drift. The property is composed of three patented claims and two fractions lying between the Caledonia and the East Caledonia and not far from the property of the Bunker Hill & Sullivan Mining & Concentrating Co.

A large body of ore has been reported on the west hill of the Intermountain Mining Co.'s properties. The report to the company said that there are "three distinct and well-defined chimneys on the west hill, all connected by an ore-shoot of considerable dimensions". It is also stated that these bodies contain large amounts of silver-lead ore. The Caledonia Mining Co. is disbursing the regular quarterly dividend of \$26,050. This is at the rate of a cent per share. The company has 1800 stockholders. The current disbursement will increase the total dividend payments to \$4,141,950.

Wallace.—The shaft being sunk jointly by the Federal Mining & Smelting Co. and the Marsh Mines Consolidated from the Russell claim of the Marsh has attained a depth of 350 ft. from the tunnel-level. The shaft is following a vein which, it is averred, is the same as the Hecla east orebody. The Russell shaft has reached a horizon to which the Hecla is said to have raised on ore at the western part of the shoot. The shaft and the raise are reported to be 280 ft. apart. Whether the course of the orebody follows the horizon or parallels the fault-line is not known. If it parallels the fault-line it should be reached in 280 ft. of sinking, the angle of the fault being 45°, but if it follows the horizon it may be reached with any round of shots. The orebody is said to be 800 ft. long and to be rich in lead and silver. The Russell vein is nearly vertical at the bottom of the shaft, and its walls are well defined. The shaft is proceeding at the rate of 5 ft. per day.

The Nabob Consolidated Mining Co., in the Pine Creek district, is operating two shifts daily and expects to operate three in a few days. Four stopes are yielding ore and more are being prepared. The mill is producing a concentrate containing an average of 53% lead, but the tables produce 54% and the jigs 60%.

NEW MEXICO

Lordsburg.—The main shaft of the 85 mine, in the Virginia mining district, some three miles south-west of Lordsburg, is being sunk an additional 300 feet.

Red Rock.—It is reported that a deal has just been closed by which capitalists from Battle Creek, Michigan, will take over the fluorspar and plant holdings of the Great Eagle Mining Co., at Red Rock, about 30 miles north of Lordsburg. The purchasers will form a new company under the name of the Great Eagle Fluorspar Co. The consideration of the sale is said to have been \$200,000, of which a considerable portion was cash. This property is believed to be one of the largest fluorspar mines in the entire South-West, having opened up a vein which, on the surface, was 5 ft. wide and has increased in depth to approximately 30 ft. wide. The development, mostly by tunnels and stopes, is reported to show, blocked out, 60,000 tons of ore valued at \$30 per ton, or \$1,800,000 total, above the lower tunnel-level. New equipment is being purchased and shipments are reported daily. It is announced that Mr. Wentworth, president of the Battle Creek Sanitarium, is president of the new company.

Boston Hill.—Rich gold and silver ore is reported at the Silver Spot mine. Assays show over an ounce of gold per ton and 13 oz. of silver, with 25% manganese. Efforts have been made, which it is reported have recently met with success, to secure adjustments in freight-rates on manganese ores which would permit resumption of shipping of manganese from Boston Hill.

Silver City.—The American Fluorspar Co., composed of Silver City business men, is reported to have started development work on a deposit of fluorspar situated near Derry, about 18 miles north of Hatch station on the Rincon branch of the Santa Fe railroad. J. W. Bible is the engineer in charge. The deposit is said to be a large one, and to contain high-grade spar.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Scott Turner is in New York.

C. M. Eye has gone to Los Angeles.

C. Erb Wuensch is here from Colorado.

Thomas Cochran was at Salt Lake City recently.

Charles A. Mitke has been at Tyrone, New Mexico.

A. T. Thomson, of New York, is at Douglas, Arizona.

C. Colcock Jones has returned to Los Angeles from Mexico.

William D. Grannis, of Kingman, Arizona, was here last week.

Otto N. Ruger has left Sonora, Mexico, and will reside at Bisbee, Arizona.

Fred. E. Wood, of Denver, is examining shale deposits near Elko, Nevada.

Edwin T. Hodge is general manager of the Liberator mine in British Columbia.

Downie D. Muir, Jr., has returned to Salt Lake City from British Columbia.

S. M. Soupcoff has returned to Salt Lake City from British Columbia and Montana.

Harold Cogswell is with the Idaho Maryland Mines Co., at Grass Valley, California.

Stanley N. Graham is now professor of mining in Queens University, Kingston, Ontario.

William Wraith, of New York, was at Salt Lake City recently on his way to California.

Samuel W. Cohen, of Montreal, sailed on the 'Empress of France' on October 6 for Europe.

Robert D'Eichthal and Albert Dellanger, of Paris, France, have been visiting the mining districts of Utah.

Lloyd C. White has resigned as consulting engineer to the Simon Silver Lead Mines Co., of Mina, Nevada.

Edwin L. Forbes has accepted a position as auditor for the La Fe Mining Co. at Guadalupe, Zacatecas, Mexico.

William W. Adams, superintendent for the U. S. Smelting, Refining & Mining Co., at Grantsville, is in San Francisco.

J. I. McGeorge, formerly with the Silver King Coalition Mines, at Park City, Utah, has moved to Florence, Colorado.

Arthur B. Foote, manager for the North Star Gold Mines Co., at Grass Valley, is taking a short holiday in San Francisco.

Walter R. Vidler, superintendent for the Vanadium Corporation of America, at Page, Oklahoma, is at Long Beach, California.

L. Ibanez Velasco, assayer for the American Tin Corporation at Hill City, South Dakota, has moved to Sabinas, Coahuila, Mexico.

W. B. Plank has resigned from the U. S. Bureau of Mines to become instructor of mining engineering at Lafayette College, Easton, Pennsylvania.

G. C. McElroy has been assigned as engineer in charge of U. S. Bureau of Mines rescue car No. 11, succeeding R. V. Ageton, who went to a similar position in Michigan.

Frederick Lyon, former managing director of the Mammoth Copper Co., and A. P. Anderson, mining engineer for the U. S. Smelting, Refining & Mining Co., visited the property at Kennett last week.

John Smeddle, recently at Guanajuato for the Cubo company, is on his way to New York by way of Zacatecas, and will then return to Mexico for the La Fe Mining Co., at Guadalupe, Zacatecas.

George L. Kaeding, having finished a complete plant for the driving of a long development tunnel for the Consolidated Cortez Silver Mines Co., in Nevada, has resigned as general superintendent and is leaving for Mexico.

THE METAL MARKET

METAL PRICES

San Francisco, October 19

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	18.75
Lead, pig, cents per pound.....	7.50-18.50
Platinum, pure, per ounce.....	\$95
Platinum, 10% Iridium, per ounce.....	\$135

Spelter, cents per pound.....	9.00
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

October 18.—Copper is inactive and weak. Lead is quiet and steady. Zinc is lifeless but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

GOLD SHIPMENTS

"The Boston News Bureau" publishes the following from London: "There is to be no change in the policy of the British government regarding export of gold to New York, and large shipments of yellow metal will continue indefinitely. Volume will be limited only by the output of the mines, as it is understood the major part of all gold arriving in London will be sold for American account. Reports of gold arrivals in New York appearing in the financial columns of the London newspapers are now taken as a matter of course.

"None of the gold recently shipped has been on the Government's account. Shipments to cover the British share of the Anglo-French loan were completed long ago. All the gold now going is on private account, and the export is not merely permitted, but promoted by the British as tending to restore healthy financial relations. Every shipment of gold means that bills are being paid in that metal in New York as the easiest and cheapest way of settlement. A large part of the commodities represented by these payments are goods of British manufacture. The British Treasury sees no advantage in having the gold held in Great Britain. The reserves in the Bank of England cannot be augmented. The English banks are amply protected. With London as the world's immediate gold reservoir, the British government is always in a position to regulate its outflow.

"Just now its interest is in having a good deal of gold flow into the vaults of the Federal Reserve Board. British and American finance is so closely interwoven that the British treasury takes almost as great an interest in our financial structure and transactions as it does in the Bank of England. The theory is that the supply of British gold to the Federal Reserve Board is a sustaining influence that will react favorably, not merely to British interests but will help to keep our Federal banking system in a favorable position as regards world finance.

"Mention has been made recently of the decrease in the world's supply of gold, which it is estimated will this year fall below 270,000,000, a 27% decrease from the world output five years ago, when it was over 298,000,000," and Samuel Montagu & Co. state that the gold imports and exports of the United Kingdom for August were:

	Imports	Exports
Russia	£ 715,530
Sweden	40,400
Netherlands	6,636	£ 530
Switzerland	4,300	1,320

MONEY AND EXCHANGE

Foreign quotations on October 19 are as follows:

Sterling, dollars: Cable	3.43½
Demand	3.44½
Francs, cents: Cable	6.44
Demand	6.45
Lire, cents: Demand	3.85
Marks, cents	1.51

Eastern Metal Market

New York, October 13.

Extreme dullness characterizes all the markets. That the worst has passed is a quite general belief, particularly in some well-informed quarters. The observance of Tuesday, October 12, Columbus Day, as a holiday was a damper on business.

Copper buying is exceedingly light, though it has increased a little with a further fall in values.

The tin market is very quiet with consumers uninterested and dealers only spasmodic buyers.

The lead market is the firmest of all, but is without animation. Prices are stationary.

Quotations for zinc are lower and demand is insignificant. Antimony is quiet and unchanged.

IRON AND STEEL

The expectation of lower prices still controls the steel market, but the readjustment is slow-paced, irregular, and confused, says 'The Iron Age'. This week signs of changed conditions have appeared in wire-products, tin-plate, and some other lines which previously had escaped the effects of the business reaction. Buyers of nails who have readily paid independent makers' prices are now holding off and some cancellations are reported. The weaker tendency in tin-plate comes with the passing of demand from makers of perishable-food containers. The largest independent producers, with three months business on their books, are generally maintaining their position.

Steel-ingot production in September was substantially the same as in August—2,999,551 tons by 30 companies, which made 85% of the total in 1919, as against 3,000,432 tons in August. For the entire country the September output was thus about 3,524,000 tons, or at a yearly rate of over 42,000,000 tons.

The re-selling of pig-iron has increased to such an extent as to dominate the market in leading centres, with almost no buying from furnaces. Some blast-furnaces may stop in the event of lower pig-iron prices with no accompanying decline in coke. The persistently high market for coke, \$17 to \$18 being paid on spot shipment, makes a serious problem for merchant blast-furnaces.

COPPER

Conditions in this market are by no means improved. Prices, forced down by dealers and some small producers and perhaps even by some large ones, have fallen to lower levels. Just what the market is, it is difficult to definitely say. One representative of a large producer placed the range for electrolytic copper at 17 to 18c., New York. It can definitely be said that small lots of electrolytic have changed hands at 17.50c., which we quote as the market for both Lake and electrolytic. It is possible that as low as 17 to 17.37½c. could be done, but there has been no fair test on a large scale in the absence of demand by large consumers. They are evidently waiting to see what the bottom will be as a result of a nation-wide lowering of commodities in general. There is a note of optimism, however, as to the future and the belief of a radical change for the better by November 15.

TIN

The week has again been a quiet and featureless one. There is almost no demand. Consumers are uninterested and buying by dealers has again fallen off owing to the unsuccessful attempt of one dealer a week ago to revive the market. This was referred to last week. Even on the New York Metal Exchange business has been light. There was a sale on October 5 of 25 tons of spot Straits under the hammer at 42c. On October 7 there were sales of 75 tons of

Straits for October-November shipment in three lots of 25 tons each at 43.25, 43.37½, and 43.50c., respectively. The quotation for spot Straits on Monday was 41.50c., New York, and in London it was £265 15s. and future standard £269, all declines from a week ago. Because of the holiday on Tuesday, yesterday, and the lower London market, no business was expected until today. Arrivals thus far this month have been 1130 tons with 5065 tons afloat.

LEAD

There is very little to be said about the market, which has undergone few changes. More metal is being offered, both foreign and domestic, with sellers seeking orders but buyers very scarce. Imported lead is available at around 7.50c., New York, or seaboard, which establishes the Eastern market; the quotation of the leading interest remains at 7.75c., New York, but it is not selling. Domestic lead has sold for prompt shipment from the West at a slight concession from the price of the American Smelting & Refining Co., or equivalent to 7.70c., delivered at some Eastern points. The outside market is quoted at 7.35c., St. Louis, while that of the Trust is unchanged at 7.50c., St. Louis.

ZINC

There is very little demand and producers are not quoting and are selling only to favored consumers for hand-to-mouth needs. Prime Western, as established by imported metal re-shipped from Europe, is quoted at 7.50c., New York, while domestic zinc is quoted at 7.35 to 7.40c., St. Louis. An inquiry for a substantial amount for delivery in the first quarter at 7.40c. offered, St. Louis, was frowned upon by sellers. A feeling of optimism is current, however, that the bottom has been reached and that some will sell higher inside of two months. While imported metal is a factor in this market it is not expected to increase. Estimates place the total amount contracted for for importation at about 7000 to 7500 tons.

ANTIMONY

The market is quiet and unchanged at 7c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The market is unchanged. Virgin metal, 98 to 99% pure, is held by the leading producer at 34.90c., producer's plant, while other sellers handling foreign metal largely ask 29 to 30c., New York.

ORES

Tungsten: The market is without developments of any significance and demand is very small. Quotations are largely nominal and unchanged at \$4.50 up per unit, depending on the ore, its quality, source, and delivery. Prices for ferro-tungsten are unchanged. High-speed steel is down to \$1.10 per pound.

Molybdenum: Quotations are unchanged in a very dull market at around 70c. per pound of MoS₂ in regular concentrates.

Manganese: About 2000 tons of Indian high-grade ore has been sold at around 55c. per unit, seaboard, the lowest in some months.

Manganese-Iron Alloys: There is no demand for ferro-manganese and prices are unchanged on a basis of \$170, seaboard, for foreign and domestic alloy. Production continues heavy, having been 27,686 tons in September, according to the blast-furnace reports of 'The Iron Age'. Re-sale alloy, at least, could be purchased at a concession, it is believed. The spiegeleisen market is quiet but steady at \$80 and \$82.50, furnace, for the low and high-grade product, respectively.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

'SONIC' TRANSMISSION OF POWER

There are at present five methods in commercial use for the transmission of power, namely, steam, direct mechanical, electric, compressed air, and hydraulic. 'Wave-transmission' and 'sonic transmission' are alternative names used to describe a sixth method in which are employed wave-motions or pulsations set up in an enclosed column of liquid. The liquid (usually water) is contained in a pipe connecting the apparatus generating the wave-motions to the machinery which applies them to useful work. Although apparently similar to hydraulic transmission, the underlying principle of 'wave-transmission' is totally and absolutely distinct. In hydraulics a continuous flow of liquid or motion of the

There is no continuous flow, the fluid progressively moves forward and backward about mean positions. The wave thus travels through the column of liquid and gives up its energy to the motor at the far end. The motor is a simple mechanism for converting the waves of energy into any desired mechanical action.

Taking the simplest form of 'wave-transmission', imagine two cylinders fitted with plungers, the cylinders on the underside of the plungers being connected together by a long pipe completely filled with water. If one of the plungers is moved rapidly up and down it will set up at each downward stroke waves of compressed water, which traveling along the pipe at the speed of sound (about 4800 ft. per second) will exert their energy on the plunger at the far end, and if this be suitably loaded, a simple reciprocating motion will be produced in exact synchronism with the reciprocations of the first plunger.

Wave-transmission equipments are inexpensive to manu-

Wave-Generator, Electrically Driven

Wave-Power Drill

liquid column as a whole invariably occurs, whereas in 'wave-transmission' there need be no direct or continuous flow, the particles of the liquid merely pulsating backward and forward about a mean position.

Water is compressible. Owing to the degree of its compressibility being very small compared to many materials in daily use, the idea that water was incompressible came to be accepted even by engineers. For the first time in the history of mechanics advantage is taken in 'wave-transmission' of the elasticity of water (and also of oil and other fluids) to transmit energy.

What occurs in 'wave-transmission' can be illustrated by simple analogy. In the ordinary speaking-tube, pulsations set up in the contained air by the vibration of the speaker's vocal cords travel in the form of sound waves to the far end, where their energy is utilized in reproducing the vibrations in the ear of the listener. The column of air in the tube does not flow through the tube, but the particles merely subjected to small movements to and fro as the sound-waves pass along. Similarly in 'wave-power transmission' the pressure impulses set up by the wave-power generator travel through the column of fluid contained in a metal pipe which connects the wave-power generator to the wave-power motor.

facure, simple in construction, and practically 'fool-proof' in operation. They consist of:

Wave Generator: One or more metal cylinders each fitted with a piston connected by a crank-shaft to any type of high-speed prime mover such as an ordinary steam or internal-combustion engine or electric motor.

Wave Motor: One or more metal cylinders each fitted with a piston, designed to receive the power-wave at the intake end. The other end of the piston is suitably connected to the tool or other mechanism desired to be operated. The simplest application is found in such appliances as rock-drills and riveting-hammers in which the piston is used as a floating hammer and strikes directly on the shank-end of the drill-steel or rivet-snap.

'Wave-Transmission' Pipe-Line: Ordinary rigid or suitable flexible piping is used to contain the liquid which extends from the wave generator to the motor, and is referred to as 'the liquid column'. Various kinds of fluid may be used, from water to heavy oil. The highest transmission efficiency is, however, obtained through water.

In many ways electricity offers an excellent analogy to explain both 'wave-transmission' and hydraulics, ordinary hydraulics being represented by the continuous current and

'wave-transmission' by the alternating current systems. From the scientific and practical point of view one of the most interesting facts about 'wave-transmission' is this similarity in many features to alternating-current electrical transmission. The points of resemblance are not mere coincidences. They go to prove the important fact that this purely physical method of transmitting energy is closely allied and is for all practical purposes a sister method, to the alternating-current electrical system. Anyone with a knowledge of electricity will find it easy to understand 'wave-transmission'. The laws and formulae of wave and of electrical transmission coincide to the extent that they are nearly interchangeable. Most of the phenomena of electricity have their parallel in 'wave-transmission'. For instance there are direct equivalents for volts, amperes, frequencies, angle of phase, induction, capacity, resistance, condensers, transformers, and single-phase or poly-phase systems. In both systems there are used generators, rotary and reciprocating motors, and transmission lines.

G. Constantinesco is the inventor and W. H. Dorman & Co., Ltd., Stafford, England, is manufacturing a complete line of tools to take the place of compressed-air systems. The Dorman company claims simplicity, portability, low initial cost, and safety as leading features of their equipment and estimate the comparative efficiency as follows:

	Compressed air	Wave-power transmission
Mechanical efficiency over all.....	10%	50%
Cost of maintenance per annum in proportion to the original cost of tools.....	100%	33%
Capital cost of plant, including prime mover.....	100%	50%
Power required to be put into the system to pro- cure 1 hp. at the working-face.....	10 hp.	2 hp.

This method of transmission was used during the War for 'C. C. gears' for automatic firing of aeroplane guns and more than 30,000 equipments were made. Generators are constructed in sizes from 10 hp. up and for frequencies up to 50 cycles per second.

SULLIVAN LIGHT MODEL DRILL SHARPENING MACHINE

The success attained by the adaptation of the all-hammer process in sharpening and shanking drill-steel as incorporated in the Sullivan drill-sharpening machine, has recently induced the manufacturers to design a new-model sharpener, embodying the same principles but of smaller and lighter construction, suitable for making and sharpening bits on the steel used in the standard sizes of hammer drills. This machine, which is shown in the accompanying illustration, is known as the Sullivan Class B sharpener, and is designed for handling solid or hollow steel of any section up to 1½ in. diameter, and to make bits up to a maximum gauge of 2½ in.

The Class B sharpener weighs 1500 lb. as compared with 4000 lb. for the larger machine, occupies a floor area of 4 by 2½ ft., and stands 5 ft. high. The essential features of the Class B sharpener consist of a horizontal hammer cylinder and piston, operating a dolly for upsetting, and a vertical cylinder and piston operating dies for swedging the drill-bits or shanks. For upsetting, the steel is clamped in steel dies mounted in the lower, or stationary, and upper, or movable, jaws of a yoke or vise operated by a horizontal air-cylinder situated in the base of the machine. The two hammer cylinders are modified Sullivan DR-6 drills, equipped with floating hammer-pistons, and a valve motion which imparts a blow of great strength and liveliness to the dies and dollies. Air is admitted to the horizontal hammers by the same valve mechanism which controls the vise. In order to secure the advantages of the floating hammer-piston in the vertical member of the sharpener a novel construction has been employed. When air is admitted to the vertical hammer-cylinder, the pressure acts on top of an annular piston fitted in the lower cylinder-head, which forces the upper

vertical swedging-die down against the steel and holds it in this position in the same manner as the hand blacksmith, or his assistant, holds the flatter or swage in hand forging. The vertical hammer then strikes against the die, drawing out the corners of the steel to proper gauge and thickness.

In making or re-sharpening bits the steel is shifted from one hammer to the other, being alternately upset and

swedged until of the proper gauge and shape and the wings, corners, and the cutting edge is properly drawn out to be uniform, and of the right thickness and angle. With a little practice perfect bits of the usual shape are made in one heat, in a minute or less, on either solid or hollow steel. Ordinary dull bits may be sharpened in from 20 to 25 seconds. In making shanks one heat is sufficient to forge those that require upsetting only, or swedging only, and two heats are necessary for shanks requiring both upsetting and swedging, such as the lugged or ear shanks used on Sullivan DX-61 and DR-6 drills. The Class B sharpener is fitted with a number of improved devices, which enable ordinary and special operations on the drill-steel to be performed with a greater measure of economy and time, and convenience for the operator. As it has been found that a drill-steel punch for opening the hole in hollow-steel bits and shanks is a practical necessity, such a punch has been built into the new machine. The double-taper bits which are doing so much to reduce the cost of mining can be accurately formed on the new Sullivan sharpener by means of an adjustable gauge-plate and dies, which are operated by action of the clamping-yoke or vise. Sixteen different gauges can be provided by means of the gauge-plate which is controlled by a key.

ONE EASY STEP

No. 86 Marcy Mill,
showing sectional
view of grate.

This Marcy Ball-Mill will take coarse feed and reduce it to any fineness

With the ordinary ores there is no crushing advantage in running two mills in tandem. Coarse ore mixed with balls of many sizes results in an economy over the tandem arrangement. The coarse ore assists in crushing the fines. The ultimate fineness is determined by the classifier or screen, with a 300% circulating load—this represents three stages and the very action of the balls and the migration through the mill is graded crushing.

Literature describing the Marcy Mill best suited to your requirements will be sent if you will write an outline of conditions.

T. A. RICKARD, . . . Editor

THERE are aids more urgent than the bonus on gold that the Californian miner ought to have. As soon as the recent rains started to swell the mountain streams the State Railroad Commission gave permission to the 'movies' to run longer hours and to the merchants to light their show-windows and electric signs more freely, but left the mining industry 20% short of its normal power.

STATISTICS prepared by the U. S. Bureau of Immigration indicate a net decrease, during the year ended June 30, 1920, in the number of aliens working in the mines of this country, of more than 2000 as a result of emigration. While 3080 immigrants entered the mining industry, 5279 miners departed for their native lands. The iron and steel mills, on the other hand, gained 1515 alien recruits and lost only 174.

FIGHTING FIRES in mines is the subject of an article in this issue by Mr. H. J. Rahilly. He holds the appointment of mine-fire superintendent to the Anaconda Copper Mining Company and is therefore in a position to write with authority. We take the opportunity to compliment Mr. John L. Boardman, the editor of 'The Anode', which is the organ of the Bureau of Safety of that company, on his publication, in which we often find something to interest us.

IDAHO has reason to be proud of the fact that both the candidates for the State Mine Inspectorship are fully qualified engineers, and not, as has happened heretofore, farmers, sheep-herders, or cheap politicians. The Republican candidate, Mr. Stewart Campbell, is a graduate of the mining school in the University of Idaho and served with the engineer corps of the Army in the War. The Democratic candidate, Mr. William M. Snow, is likewise a mining engineer and a graduate of the State School of Mines; he has practised successfully in the Coeur d'Alene. Both are good men, and whichever is elected the State of Idaho will have an excellent Inspector of Mines.

DIVERSION of the traffic in copper from the railroad to the steamship is one result of the increased transcontinental freight-rates. It is announced that the Anaconda company henceforth will transport its copper from Great Falls by way of Seattle, thence by sea, through the Panama Canal, to New York. Overland the

railroad tariff is \$22 per ton; the freight by rail to Seattle is \$7.75 and from there to New York by steamship it is \$8, making a total of \$15.75, or a saving by the sea-route of \$6.25 per ton. The first shipment of 1000 tons was loaded on the 'Hannawa' of the Luckenbach Steamship Company at Seattle on October 16. Other smelting companies are likely to follow suit.

WE note that the San Francisco Chamber of Commerce advises the people of California to vote against the initiative measure to amend the Alien Land Law of 1913, as against the Japanese, because it believes that the real problem is "in the last analysis, one of immigration" and it considers that the measure contains "unnecessarily harsh provisions concerning the guardianship of the children of residents not eligible to citizenship". The immigration of those "politically ineligible to citizenship" should be forbidden by the Federal government, either by treaty or legislation, and preferably by treaty. The initiative measure is considered likely "to stir a spirit of irritation and hostility", calculated to prove "a hindrance to the Federal government in the attainment of a final solution of the question of immigration". We concur.

DECISION in the litigation between the Utah Apex and the Utah Consolidated companies over lead-silver deposits at Bingham has been made by Judge Tillman D. Johnson of the U. S. District Court of Utah. The opinion sustains the contentions of the Utah Apex Mining Company. Briefly, it determines that the ore deposits are associated with fissure-veins in the limestone and that the limestone beds themselves do not constitute 'lodes' within the meaning of the Federal mining law. We shall give the text of the decision in a later issue. The chief bearing of the decision upon controversies in other districts arises from the fact that the Court refuses to recognize the outcrop of the mineralized limestone as the apex of a lode in a locality where the distribution of the ore is associated with fissures that cross the beds at a high angle.

WE note the organization of a Mining and Metallurgical Society on the Kolar goldfield, in India. The first president is Mr. C. F. Heathcote, the resident manager of the Champion Reef mine and an engineer well fitted to preside over a gathering of technicians. At

the first meeting he said: "We do not want to flood the profession with papers on Kolar practice, but we do want it to be known that we are leading in deep mining, in the treatment of our ore, and in measures for the health, safety, and welfare of our workmen." Among the local problems on which information would be welcome is the mitigation of the effects of 'rock-bursts' or 'air-blasts', the consequence of stopes so extensive as to cause excessive pressure on the hanging wall, as in the Lake Superior copper region. Another is the alleviation of the heat incidental to deep mining, that is, the technique of ventilation. As to the mining of the ore and the treatment of it, we believe our American engineers have not much to learn from their friends in India, but concerning "the health, safety, and welfare" of workmen there is much yet to be said and done. We hope the new society will be a means for stimulating improvements in this branch of mine management.

ALTHOUGH so many of our people fight shy of the League of Nations, they approve of plans for promoting international co-operation in finance and commerce. At Brussels an International Chamber of Commerce is now firmly established. We are told that "for years, enlightened business men everywhere looked forward to the day when there would be set up in the world an institution which would serve to bring the nations together, and facilitate settlements of foreign trade problems. They had recognized that personal friendships between business men and bankers of the different nations go a long way toward minimizing misunderstandings and prejudices." So says the bulletin of the Chamber of Commerce of the United States. It is true, and it is pleasant to record, that business brings men together and establishes mutual good feeling; but is it not sad to recognize that the interest in money affairs will promote co-operation and lead to the organization of leagues for expediting business, whereas the bigger and vastly more important purpose of promoting international peace in political affairs is relegated to one side. "The necessity for co-operation in matters of world trade", says the bulletin we quote, "is realized as never before". One need not be a cynic to note that there is more care to protect the money of the worthy bankers and their friends than to safeguard the lives and happiness of the helpless millions whose fate it is to be sacrificed in war.

LIQUID OXYGEN is of growing importance as an explosive. Not long ago Mr. George S. Rice, of the U. S. Bureau of Mines, discussed the subject in San Francisco before the local section of the Institute. He has published sundry data recently. Among other facts, he states that one company, the Deutsche Oxhydric, of Surth, near Cologne, has furnished, since the Armistice, 64 plants for making liquid oxygen on the German coal-fields. These plants have a total capacity of 1820 litres of liquid oxygen per hour. At the metal mines of Germany there have been added, since the Armistice, 46 plants with a total capacity of 1407 litres, and at the potash and salt mines there have been added 14 plants

with a total capacity of 450 litres per hour. Assuming that only 25% of this aggregate capacity is utilized and that the plants are operated for only nine hours daily for 300 days in the year, this additional production of liquid oxygen would be equivalent to 8,000,000 pounds of dynamite per annum. Another interesting development is the design and construction of small portable plants for making three to five litres of liquid oxygen per hour; such plants are placed on trucks and are made easily available for various engineering activities. Liquid oxygen is an explosive that generates no injurious gases; on the contrary, it improves the air of mine-workings. For this reason we expect its use to expand in this country.

IN this issue we publish the third and last of the articles by Mr. Ingalls. We feel certain that they will have been read with keen interest. He brings into relief the gain that has come to brawn from the successful use of brain. The story of copper mining during the last decade is a case in point. If it were not for the ingenuity and inventiveness of the mining engineer and the metallurgist many of the biggest mines would not exist as a source of wages to thousands of laborers. During recent years their wages were scaled in proportion to the selling price of copper, which, in turn, was supposed to measure the profit won by the employing companies. For a time, in 1915 and 1916, the efficiency of labor did not suffer; we remember being told cheerfully that the increase in wages in Arizona, from \$3.50 to \$5.00, did not cause an increase in the cost of producing the copper. Everybody was happy. This did not last long. The workers slacked; some of them took a holiday and thereby caused disorganization; others felt the relaxing effect of prosperity; it is certain that higher wages and shorter hours diminished the output per man per shift. Various classes of workers fared unequally during the period of expansion due to the exigencies of war; the metal miner fared best. Theoretically it might be desirable, as Mr. Ingalls suggests, if corporations earning an excessive profit would pay a bonus to their employees, but would the employees of the successful corporation deserve more than those employed by its competitors? One may say also that the stockholders in one corporation are not as individuals more deserving than the holders of stock in the less successful enterprises. Even if one conclude, with Mr. Ingalls, that the profit is due to managerial excellence, that is, to the superior intelligence of a few directing minds, one must face the fact that much of the success of mining is due to luck. Who is to decide how much is due to luck and how much to skill? Any scheme of economics that tries to correct the irregularities of life on the basis of desert, of what various people deserve, is stultified at the start. The greatly successful industrial enterprises of this country are due first to natural resources, next to the development of technicians competent to exploit them efficiently, and last to an adequate supply of labor. Each is essential. The technician, or the engineer, using the word in its broadest sense, is the connecting link; his is the mind that applies muscle to mat-

ter, labor to material, for the purpose of turning the matter and material to fruitful use for the benefit of mankind. Only one man in sixteen is capable of directing his own labor.

Our National Responsibility

As Mr. Elihu Root says: "A large majority of the American people earnestly wish for an organization among civilized nations, through which the nations shall co-operate to prevent future wars, and that the United States shall do her full share in that organization". The wishes of this majority have been frustrated by throwing the issue into party politics and thereby creating a prejudice that now makes it difficult to consider the subject judiciously. Most of us will place the blame on both sides, on the President for disregarding the treaty-making power of the Senate and on the group of Senators who so obviously determined to disregard the welfare of humanity in their keen desire to humiliate the President. The consequence has been an entire failure in constructive legislation looking toward a League of Nations and a perversion of the co-operative spirit that marked our effort in the War. The fine emotions of that heroic period have been allowed to subside and an Americanism has been invented that has "no foundation whatever in any of the authentic traditions of the Government". We who went forth nobly to keep the world free for democracy are now bidden to let the world, the old world of Europe, stew in its own acrid juice. It is none of our business, say the politicians; we have done enough, let us attend to our own affairs; if we allow ourselves to be tied by this Covenant we shall have to send our young men to fight in quarrels that do not concern us, we shall become entangled in all sorts of wars for which we are not in the least responsible.

At the bottom of much of the opposition to our underwriting the Covenant is an earnest feeling of pacifism and a desire to keep out of more wars. The people of the United States desire peace intensely and they hate the idea of becoming mixed in the traditional enmities that are still disturbing Europe. If we could avoid war by political detachment from the rest of the world, we would be justified from the point of view of enlightened self-interest in keeping aloof. A man's duty to his own household comes first; a Government's fundamental duty is to protect the welfare of the people it represents. The pose of minding one's own business is not heroic, but it may be called shrewd. Unfortunately the conditions of the world in which we live render any such detachment or isolation entirely impracticable. We are not living in the days of Washington and Hamilton; they would smile at those who quote them in regard to "European entanglements" because they would be the first to recognize the changes that have taken place in political geography. There is more intercourse today between America and Europe than there was a hundred years ago between North Carolina and South Carolina. The Atlantic is less of a barrier today than the English Channel in Napoleon's time. It should not be necessary to empha-

size this point; the incidents of the late war have proved in most dramatic fashion to what extent time and space have been contracted in consequence of modern inventions, and they suggest how much the development of aerial attack may further shrivel the intervals of space upon which in Washington's day it was possible to count as a factor of political separation and national detachment. Since the Republic was founded we have been drawn into both of the two general European wars, despite every effort to keep out of them. The opponents of Mr. Wilson say rightly that he spoiled the national purpose, as Mr. Root says, of co-operating for the prevention of future wars, by playing a lone hand, in despite of the Senate; but are not Mr. Wilson's opponents doing their best to drive our country into exactly the same kind of blunder, by urging the Nation to play a lone hand in world affairs and to ignore the partners with whom but lately we played a winning game against our common enemy in the common interest, as we believe, of mankind? Shall we wash our hands of the War with our purpose half-fulfilled? Today we are economically the richest and most resourceful nation in the world; shall we shirk our responsibility as a trustee of the common civilization to which we belong? Humanity is in travail, it is making a painful effort to emerge from the barbarism of war, the inheritance of the jungle; shall we stand by as a selfish spectator? Would Washington or Lincoln approve it? No answer is needed; we dishonor their names by the mere supposition. All this talk of surrendering sovereignty to the League supposes that an association is possible without restriction of individual freedom; it is the freedom to make war and the liberty to plunge millions into death and destruction that we want to limit. We have entered into numerous arbitration treaties, each one of which has meant some parting with our liberty of action. Sovereignty is lost only when liberty of action is taken from a country against its will. The State cannot function without limiting the liberty of the individual citizen, yet he is not conscious of losing his essential freedom to do what is right and proper. The whole structure of civilized life is based upon the surrender of self-assertion for the sake of the common good. We have taken from the individual man the right, which he brought with him from savagery, to attack his fellow. We must take from a nation the similar right, also a belated barbarism, to attack its neighbor. For nations as for individuals we substitute a court of appeal, with power to arbitrate, adjudicate, and if all else fail then to outlaw the offender. The swashbuckler and the bandit among nations must be suppressed; the double standard of conduct as between individuals and as between nations must be rendered obsolete. That is the purpose of the League of Nations. Surely it is a noble purpose and worthy of our support as the chief exponent of the democratic idea. For that we fought but lately with no inconsiderable enthusiasm. We esteemed our young men to have died for a noble cause. We talk now about erecting memorials to them in the shape of monoliths, towers, and sacred fanes all over our broad land. The sentiment is excellent, but somewhat hollow. To

those who have stood on the desolate battlefields of Europe and seen with their own eyes the sacred ground upon which millions of men died for the sake, as they believed, of putting an end to wars, it seems but a mockery to erect structures of granite and marble. The only memorial worthy of the unreturning brave is the consummation of the idea for which they died: a league of the nations for the enforcement of peace.

The Ownership of Mine-Water

The hearing of the suit of the Snake Creek Mining & Tunnel Company v. the Midway Irrigation Company, on appeal from the decision of Judge Tillman D. Johnson of the U. S. Federal Court for the District of Utah has been set for December next, when the case will be argued before the U. S. Circuit Court of Appeals at St. Louis. To the mining industry the final outcome of the suit is sufficiently important to warrant discussion at this time. The Snake Creek tunnel, which, by the way, is really an adit, was projected jointly by the Judge Mining & Smelting Company, owner of various mines and of a large area of mining property in the Park City district, and by the group associated with Mr. Jesse Knight of Provo; but the Judge company is now sole owner by deed of conveyance of all property, water, power contracts, and other assets formerly owned by the Snake Creek Mining & Tunnel Company. The tunnel has been driven 14,500 feet from the portal on Snake creek toward the Daly Judge mine, the purpose being threefold: to afford drainage of the Park City properties at a lower level, to explore the territory traversed, and ultimately to provide a means for cheaper haulage. Two 18-inch tracks or a single track of 36-inch gauge can be accommodated. The feature of the project that is the cause of controversy is the development of an unexpectedly large flow of water, the present stream being 20 second-feet with a probable increase to 30 feet by the time the tunnel has been completed. The ownership of this water is an important asset to the mining company, on account of its value as a source of hydro-electric energy; in fact, one of the factors determining the construction of the Judge electrolytic-zinc plant near Park City was the possession of favorable power-contracts, which could not have been obtained except for the title to the Snake Creek tunnel-water. The Midway Irrigation Company had certain water-rights that it believed were affected detrimentally by the driving of the tunnel; the purpose of the suit is to quiet title to any interest in the water developed by the tunnel. There is an established principle of common law providing that percolating water belongs to the soil: the crux of the question is the meaning of the word 'percolating'. The interpretation for which the plaintiff contends presumes that water issuing from a tunnel or adit belongs to the owner of the ground through which it is driven, regardless of its draining any spring or other water-channel, unless the owner of the ground in which such channel exists can prove beyond reasonable doubt that the water claimed to have been diverted comes from known channels with a definite direction of flow

leading to streams whose water is owned by the adverse claimant. When the suit was originally tried, the Judge company merely presented evidence to establish ownership of the ground traversed by the tunnel and rested its case there. The defendant company thereupon presented evidence to establish its ownership to the water, the conduct of the trial being similar to suits involving apex controversies in that elaborate exhibits and expert testimony played a prominent part. One of the plaintiff's exhibits was a hydrograph of the flow from the tunnel showing the periodic fluctuation during successive years. However, it appeared that the periods of maximum flow post-dated the peak-flow of the surficial streams by from two to three months. This, it was argued, proved that in reaching the tunnel the water from the surface must have passed through minute cracks or capillary and sub-capillary openings in the rock rather than through open channels of definite direction. Otherwise a much briefer period must have elapsed between the time of greatest surficial flow and the maximum flow in the tunnel. Sundry other arguments based on the technical testimony of scientists were advanced and the Court held in its decision that the plaintiff had proved the water to be 'percolating'.

Litigation of a similar character was discussed in our columns by Messrs. G. A. Duncan and R. T. Walker two years ago. The dispute was between two mining companies operating in the Eldorado Canyon district in Nevada. It appears that the defendant company, after a particularly dry season, sank a shaft at a point where one of the strongest faults in the district crossed a deep gulch. Water in considerable quantity was found and was pumped to the company's mill a mile and a half distant. The plaintiff, whose property was situated farther down the same gulch, found that its supply of water began to dwindle at about this time, although at the trial it was established that this decrease was noticed some weeks before the other company began to pump from its 'water shaft', or well. At any rate, operations at the plaintiff's property had to be suspended entirely owing to the inability of its mine to supply sufficient water to keep the cyanide plant in operation. At the trial it was shown that the total amount of water pumped by the defendant was only a small proportion of the decrease noted by the plaintiff, and the plaintiff was unable to establish any significant relationship between the lessening of its own water-supply and the pumping from the defendant's new water-shaft. The decision of the Court, however, did not undertake to pass upon the question as to whether water "flowing along a fault-plane entirely enclosed in rock, is or is not 'percolating' water". Mr. Walker pertinently suggested the complications that might follow an attempt to narrow the scope of the term 'percolating water', that is, to recognize a fault, fracture-zone, bedding-plane, or other vague passage-way as constituting a 'well-defined channel'. It is evident that there is enough scope for mining litigation without recognizing obscure passage-ways as definite water-channels. Were such a precedent established a company would risk some legal entanglement every time it started to sink a shaft or drive an adit.

DISCUSSION

Engineering Education

The Editor:

Sir—In your issue of August 14 you discuss engineering education and invite further discussion. I believe that a four-year course ought to be considered ample, for only a small percentage of students would be able to afford six years in college. A mining engineer once told me that the schools which insisted on a course longer than the usual one of three or four years (I presume he had in mind one of the German centres of learning) frequently turned out men who, to borrow an expressive term, were “meticulously precise”. It sometimes happens that certain data are required quickly and not altogether accurately. The man who has had a long scientific training has had inculcated in him a reverence for the greatest possible accuracy. For doing relatively precise work a highly trained man is liable to prove annoyingly slow. I give my friend’s argument, for one must acknowledge that there is a little substance in it. Yet it is open to attack from so many points of view that I find myself unwilling to make the argument mine. An engineer who must have certain information right away has been asleep somewhere along the line. I believe a man would benefit far more from his attendance at college if he were to precede it with a year’s practical experience. It is usual, of course, to spend a few weeks of each college year in a mine or mill. However, I do not think that these spasmodic efforts are of full value, because the average young man, and to meet the problem squarely we must bear in mind the average young man, looks on this period of work rather in the light of a pleasant change from the lecture-hall. As you point out, the medical student rightly serves a long apprenticeship. You perhaps remember the story of the *viva voce* examination at which the examining doctor after giving the details of a case asked, “How many grains of — would you administer?” “Twenty”, replied the student, and then on further reflection said, “No, sir, five grains”. “Too late”, was the rejoinder, “your patient is already dead”. After I had left the university I realized how short a time was actually devoted to instruction. Three sessions annually, each one of 10 to 12 weeks. Subtract Sundays and half-holidays and there is not much left. While recognizing that the university is an institution where character ought to be molded and strengthened and where one should be taught how to think, I feel that more hours of each day should be spent in the lecture-room or the laboratory. Five or six hours daily are inadequate. I am therefore of the opinion that

instead of lengthening the college period, from four years to six, the extra time necessary to embrace courses in economics, etc., could be made easily enough by calling for a seven-hour day. That would leave ample opportunity for social intercourse and evening study. I am glad you stand for an all-round rather than a specialized training. A mining engineer ought not to be dumb on every subject but mining. The university attempts to cover too much ground, so that the knowledge reposing in the brain of the graduate is a criss-cross of impressions rather superficially received and written in a species of short-hand which he himself cannot always decipher. I plead for the teaching of principles without an attendant mass of useless trimmings.

Umpire Assays

The Editor:

Sir—A few days ago, during the course of conversation, an assayer of this city complained rather bitterly of the lack of a definite standard for umpire assays of gold and silver ores, and it seems to me that the time has arrived for making ‘corrected assays’ in determining the precious-metal content of these ores. By ‘corrected’ assay I mean adding to the ordinary fire-assay a correction, properly determined, for the loss in cupellation and when necessary for the loss in the assay slag. At present ore-contracts are made on the basis of payment for 95% (usually) of the silver content, which in turn is based on the theory that smelter losses average 5%. The fact of the matter is that while the apparent loss of silver may be 5%, the real loss varies with the ore treated and its true amount is obscured by the metallurgical gains made on the silver not paid for because of the cupellation and kindred losses.

The harm from this practice is due, not so much to the actual quantities involved, which are comparatively small, but to the lax work and uncertainties resulting, especially the uncertainties involving the umpire assayers.

W. J. Sharwood, at the conclusion of his experiments, says that the percentage of cupellation loss varies inversely with the cube root of the weight and is 1% for a 1000-mg. button of silver and 10% for a one-milligramme button. Contracts usually specify that silver is to be determined by the scorification assay and 0.2 A.T. is the amount usually taken for assay, so one milligramme

would represent 5 oz. per ton or \$5 at the present price, and 10% would be 50c. per ton, a not insignificant item to large shippers. To this is to be added the uncertainty due to changes of heat and draft in the muffle, the presence of impurities, and the assay-slag loss. In the case of ores containing 100 oz. per ton the cupellation loss would be 3.7 oz. per ton, and if the ore contains zinc and tellurium in appreciable quantities it would be more. If the sample is referred to an umpire without statement as to the method of assay, he will have to decide whether to use crucible or scorifier and if the latter whether to use 0.1 or 0.25 A.T. for a charge, which of itself will cause a variation in the result obtained. Of course, he is supposed to act "in accordance with good practice", but does good practice demand that he should cupel three or four buttons together to reduce the loss, or does it not? It cannot be said that he should get the maximum amount possible because this might even be more than the silver in the ore. There is no definite answer to the question, but there should be, because this alone accounts for many discrepancies between shipper and buyer. Has the shipper the right to run three or four assays and scorify the buttons before cupelling so as to reduce the cupellation loss and if two why not eight? The practice seems to be that the shipper can run any number or combination, on which by umpiring he can win enough to pay for the assay bill. This is passing the buck to the umpire and is just the thing that was being complained about. Why let such a condition exist? Why not run proof-assays, as is done in bullion work, and if the amount be too small to pay for the work of a proof-assay then make a correction to bring the result to the 'proof' in accordance with the figure shown by practice to be necessary. The more accurate knowledge of the true precious-metal losses resulting from this practice would result in better recoveries in many cases. The only way to get the practice adopted is for the shippers to insist on its use, because naturally the buyer will not. In selling zinc-precipitate it is quite important.

Oil-Shale and Shale-Oil

The Editor:

Sir—To answer your question off-hand, "What does it actually cost to mine a ton of shale?" is like answering similar conundrums, "How old is Ann?" How long is a piece of string? Where does Senator Harding stand on the League question?

Almost every group of shale-lands is a law unto itself. For instance, it is definitely known that at the Catlin property in Elko, Nevada, a 5-ft. vein of shale is now being mined at a cost of \$1.25 per ton, and this figure is expected to be scaled down to \$1 under steady operations, but this means nothing to operators in the adjoining States of Utah and Colorado, where conditions are quite different.

When I first became interested in the shale deposits of Utah, and after having sampled several of the beds that

were practically free from overburden, it was evident that these deposits, ranging from 10 to 100 ft. in thickness, would have to be handled by up-to-date means and under the direction of an efficient mining engineer.

Fortified with photographic views of these workable deposits, I interviewed Daniel C. Jackling, of Salt Lake City, and laid the matter before him. Mr. Jackling advised the employment of the Stimpson Equipment Co., of Salt Lake City, and Mr. Paul T. Boise, of that firm, made an examination of the property and laid out plans for mining equipment, handling material to the crushing plant, and conveying same to the bins, estimating cost of same at less than 40c. per ton.

Last month I wrote to Mr. Jackling, asking for his estimate of mining cost on another group of shale-lands located in Rio Blanco county, Colorado, where there is a bluff of workable shale about 50 ft. thick, practically free from overburden, and at an elevation of 300 ft. above the proposed plant-site. In his reply, received a few days ago, Mr. Jackling estimates a figure of 50c. per ton as being safe for present calculations, comparing costs with those obtaining at the Chino and Nevada copper properties.

Underground mining of shale will present many difficulties, as shale is a stubborn product to deal with. I think, however, that James Doyle, of Denver, who has located and validated large tracts of land in both the States referred to, could throw light on this subject, as he is a practical mining man and the work done by him shows intelligent direction. I do not think, however, that much underground work, if any, will be undertaken so long as there are so many attractive quarrying prospects available.

The oil-content in the shale of the Uintah basin ranges from a trace to 60 gallons of oil per ton of shale with plenty of tonnage available that will average about one barrel of oil. These higher-grade shales will average in by-products about 27 lb. ammonium sulphate, 2% wax, and 5% asphalt. Some thin strata ranging from two to four inches in thickness, show as high as 76 gallons of oil to the ton of shale, but no practical man would give serious attention to these small deposits.

The commercial success of the shale-oil industry will depend largely on the process adopted for destructive distillation, and we have now 57 varieties to choose from. One Denver 'scientist' claims to recover all the oil at a trifling cost, and then from the residue he extracts gold, silver, platinum, portland cement, fertilizers, and Liberty Bonds.

About three years ago, my attention was drawn to the Wallace process, at the St. Louis Gas Co.'s plant at East St. Louis, and after witnessing several tests, it not only appealed to me, but also to others. Acting on the advice of Dr. David T. Day, the Ute Oil Co. subsequently entered into a contract for the installation of a 250-ton plant, which is now nearing completion, and will be in operation the latter end of this year.

Through a friend of mine in New Brunswick, Mathew Lodge, who with his associate Sir William MacKenzie

owns the principal shale deposits of that Province, the Wallace process was recommended to the Anglo-Persian Oil Co. of London, as being worthy of investigation; and after a year's study their subsidiary company, the D'Arcy Exploration Co., decided to install an initial plant at Moncton, N. B., and their representative, John Henderson, is now on this side to close a contract with the Wallace company.

Taking a 5000-ton mining and retorting plant, and basing the cost of mining at 50c. per ton, crude oil should be produced at a cost not to exceed 80c. per barrel. A refining plant of like capacity would cost considerably more than the retorting-plant. Tests in refining have been made by the Wells Oil Refining Process Co., of Columbus, Ohio, and show a loss in refining of about 3%. The Standard Oil Co. at its research department, in New York, on recent tests shows a loss in refining of 2%. The loss in retorting will vary from 5 to 7%. The quality of the gasoline, lubricating oil, and wax is as good and possibly better than that refined from petroleum. The wax especially is far superior to any produced up to date and has been so admitted by the trade.

HECTOR McRAE.

The Price of Gold

The Editor:

Sir—Writing upon this subject in your issue of June 21, Mr. A. Moline stated, among other things, that no matter what the premium might be on gold as regards its value in paper money, its price in terms of itself, that is, in sovereigns, is still £4.25 per fine ounce (neglecting the fraction) and he showed by example how it could not be otherwise. This is tantamount to saying that one piece of gold can only be worth as much as another of the same weight and composition. Of course, if it were pure there could be no variation in its value.

One might think that such an obvious fact would be self-evident to everyone, but, on the contrary, it is one that is by no means universally recognized. The ignorance and misconception that exists regarding this once common medium of exchange is really quite extraordinary. This applies not only to its economic functions, but also to its physical qualities. The superstition and belief in its miraculous powers that so obsessed the minds of all throughout the Middle Ages is dying hard. Even many of those who are closely associated with its production have very vague ideas as to what is actually meant by the term 'fineness' of gold and the relation this bears to its value.

While engaged in running a custom mill I have often tried, with indifferent success, to explain to a prospector why his gold was worth, say, only £3 15s. per ounce when his ore had assayed so many pennyweights per ton, worth 1s. 3d. per dwt. And anyone who has had anything to do with a public treatment plant knows that these people are not wanting in acumen. A good many years ago I was in charge of a plant on a gold mine managed by one of the 'old school' mine captains. On one occasion it

became necessary to re-smelt and refine a bar of cyanide gold that had previously been handed into the office. When the output was finally made up this individual was much perturbed to find that in spite of this particular bar being worth several shillings more per ounce, its total value was no more than before; it was slightly less, in fact. He remarked in an insinuating manner that he had observed a similar phenomenon on a certain occasion when my predecessor was in charge. I could only answer that although the coincidence was remarkable there was really no evidence of collusion. This does not profess to be a verbatim report of the conversation, which was chiefly a monologue consisting of "Where's it to, where's it to".

Even in better informed circles, and among those who, nominally at least, control the policy of some of our gold mines, one can see indications of the idea that the value of gold bullion depends upon some virtue, either peculiar to a certain mine, or that can be instilled into it by a metallurgical process, much in the way in which the quality of steel can be altered by tempering or annealing. It is probably this general failure to understand that the relative values of gold coin and bullion depend upon their respective contents in that element, and not upon some internal change, or even the impress of a ruler's head or other device, that enables quack political economists to foist upon the public those fantastic schemes for balancing the national ledger by diluting the gold contents, or reducing the size of coins.

The Japanese in California

The Editor:

Your resumé of the Japanese question as it affects California is complete and you have called attention to its importance, but I do not think that you have adequately stated the problem or the conditions governing it.

The standard of living in the United States is the highest in the world today. This is not because of our natural pre-eminence in brain power and physical ability, much as we would like to believe it. We are the direct descendants of the people inhabiting European countries, and in many cases only one generation removed, so there can be little difference in natural mental and physical equipment. Our standard of living is high because of natural resources, such as a favorable climate, and more acres of fertile land per capita than there are in any European or Asiatic country. This may hurt our pride, but it is true. We had the natural resources, ambition, and strength because of a suitable climate and proper food and so we devised the machinery to avail ourselves of the wealth at hand and thus became a nation of doers; but our standard of living has reached or nearly reached its maximum unless we take radical steps to preserve the conditions that permit its increase.

Before the War it was estimated that our standard of living required the produce of 15 acres of land per per-

son to maintain it. This does not mean that the produce of 15 acres of land had a value in dollars and cents that would pay for the material needed by one person under the present standard, but it means that, throughout the country, the corn, apples, cotton, barley, hay, and sugarcane, used direct or as raw material, necessary for the average person, required 15 acres of land to produce them. Our standard of living has not been lowered since the beginning of the War, so the estimate of 15 acres per person made prior to that time is, to say the least, a moderate one. Now there are in the United States only a little over 18 acres per person and some of that is sterile. In other words, the country is at the present time approximately self-sustaining, but there is little or no margin. It is true, we are exporting raw materials such as meats and grains, but we are also importing an equivalent amount of coffee, sugar, rubber, tobacco, and wool. To obtain the raw materials cheaper than anyone else we must depend on South American and African products, and the amounts available are becoming insufficient for the whole world, consequently we must compete with European and Asiatic countries, which, because of their lower standard, are able to offer more labor in return than we can. In other words, there is no market large enough in which we can dispose of our manufactured products for raw products at a return that will enable us to maintain our standard. We can, of course, exchange manufactures with Europe and live, as the old phrase has it, by taking in each other's washing, but this is limited by the fact that in most cases Europeans or Asiatics can better afford to spend ten hours of lower-standard life than we can spend ten hours of higher-standard, so the market will be limited to a few things in which our conditions permit us to excel. The country with the lower standard can outbid the one with a higher as long as other conditions are equal, because in reality the bidding is in hours of labor, not in dollars.

The time has come therefore to restrict foreign immigration, Japanese or otherwise, if we are utilizing all our available land in producing raw material. We are not quite doing it yet, and California is one of the most favored States in the amount yet available, but we have already reached the point at which the law of diminishing returns applies, and the next decade will see the condition reached when it will be seriously felt.

We have the example before us, or at least those who live on the Pacific Coast have. The Chinese came here as a coolie class to work in the fields at a low wage. They came in direct competition with the white laborers in the early days and their further coming was stopped. The Japanese came in much the same guise, but only met a half-hearted opposition from the unions because it was said that they would not cut the ruling schedule of wages; besides, at that time there was a shortage of labor, or there were more opportunities than there were men, and the Japanese were content to take the places that the white man did not want. They are, however, not a servile race by nature and now they have come into direct competition, not only with day-laborer but also

with the small storekeeper, the orchardist, and gardener, and even the large rancher and big merchant. By their willingness to cut prices and work longer hours they are forcing down the standard of living of the white race on the Coast; that is, they bid more hours of work for the best opportunities and there are not enough opportunities to go around. The Atlantic Coast has not felt this competition directly and hence regards their presence here with equanimity.

There are only two classes that desire the presence of the Japanese: The first is the employer of labor on a large scale. He needs more laborers than are available at the moment and besides he needs them to keep the misguided efforts and arbitrary actions (and sometimes not misguided ones only) of the labor-unions in check. Numerically this group is small but influential. The other class consists of those with a militant belief in the Universal Brotherhood of Man and therefore necessarily one great race of black and tans. Because the physical effect of Japanese immigration has been felt so far only on the West Coast this latter class is mainly in the East. When it comes down to bedrock facts very few people of any race, white, black, or brown, really believe in the one big race idea, but there is a large class of people who think they do, until brought face to face with the results.

I think the question is answered. I have seen it stated that California cannot prohibit the ownership of land by Japanese because the treaty between the United States and Japan permits such ownership, and the present law is therefore a violation of the treaty. The treaty provides that citizens of both countries may rent and own warehouses, buildings, etc., for residence and commerce and lease land for such purposes, but no provision is made for the purchase of land. Japan itself has a law prohibiting the ownership of land for foreigners, and this law applies to Americans. Furthermore, the treaty says "It is however understood that the stipulations in this and the preceding Article do not in any way affect the laws and ordinances with regard to trade, the immigration of laborers, . . . which are in force or may be hereafter enacted in either of the two countries". This is a provision that seems to cover amply any reasonable exclusion act that may be desired.

Then why all this outcry by Japan? Apparently it is a smoke-screen sent out to cover up their doings in the Orient, something to distract our attention while they repeat the Korean episode just as the cry for racial equality was raised at Versailles to furnish a *quid pro quo* for the Shantung (let us call it) appropriation. Japan's trade with the United States amounts to one-third of that country's foreign commerce. She cannot afford to have real trouble with us unless we have so far relaxed our vigilance that a victory in a clash of arms would be almost certain, but she is driven by the same force that will drive us in a few years if we do not put a stop to foreign immigration, and it is best to begin with the non-assimilable races.

C. A. GRABILL.

San Francisco, October 20.

THE SHAWMUT MINE AND MILL

The Mine and Mill of the Belmont Shawmut Mining Company—I, The Mine

By ARTHUR B. PARSONS

INTRODUCTION. The operations of the Belmont Shawmut company are interesting for several reasons. The mine, formerly known as the Eagle Shawmut, is one of the oldest on California's Mother Lode; likewise, it is one of the most developed mines and it ranks among the first in the value of its past production. The Belmont Shawmut company is a subsidiary of the Tonopah Belmont Development Co., which owns virtually all of its capital stock, acquired at the time the Belmont Shawmut was organized in 1916. This is one of three promising properties that the Tonopah company purchased pursuant to its policy of utilizing its financial resources, as well as its excellent administrative and technical organizations, for the development of new mines, to supplement the profit derived from the remarkable bodies of gold-silver ore at Tonopah that first made the success of the parent enterprise. Although handicapped by the prevalent high prices for labor, material, and power, and by the additional burden that confronts any company whose output is gold alone, namely, the fixed price for its bullion, creditable results have been obtained. In order to minimize the cost of mining comparatively low-grade ore averaging less than \$5 per ton, it was necessary to select the most economical methods of mining applicable to the orebodies, and to equip the mine mechanically for efficient operation. Of particular interest also is the development of a scheme for metallurgical treatment whereby bullion rather than concentrate is marketed. This treatment includes the cyaniding of raw flotation concentrate.

The mine lies somewhat south of the centre of the Mother Lode, about five miles east of Chinese station, in Tuolumne county (see map). It is near the site of the Hetch Hetchy reservoir, which is to supply water and

power to San Francisco, and is on the main road to the Yosemite valley. The adjacent country is remarkable for its natural beauty, being rugged and not too thickly covered with timber.

GEOLOGY. The Shawmut vein is distinguished by the characteristic outcrop of massive quartz; it strikes N.

40° W. and the dip is approximately 70° in a northeasterly direction. The rock on the hanging wall is a schist, resulting from intense metamorphism of sedimentary rocks and is readily distinguished by its dark color from the lighter brown slate of the foot-wall. The width of the vein varies from 12 to 35 ft., the average being about 18 ft. Just beneath the vein proper is a layer of impure dolomite that varies considerably in thickness; this separates the vein from a band of gouge, which, because of its unusual character, has a peculiar bearing on the methods of mining. There are three fairly distinct

kinds of ore, although sundry intermediate types grade into them. The ore styled 'sulphide' contains little free gold, but about 9% of gold-bearing sulphides including pyrite, marcasite, and mispickel. In general, the sulphide orebodies are composed of a series of well-defined lenses, with their long axes horizontal; one shoot, south of the shaft, averages 25 ft. in width and is 500 ft. long. The north, or 'quartz', orebody contains a larger proportion of free gold and is more nearly a true-fissure deposit. A third kind of ore called 'schist' is found at different points throughout the mine; it contains a smaller proportion of sulphides.

THE MINE. At the present time the working entrance to the mine is a long cross-cut adit, untimbered for the most part and about 8 by 10 ft. in dimensions. At a point 1800 ft. from the portal the adit meets the old inclined shaft that formerly was used for hoisting ore to the surface 400 ft. above the adit-level. Some years ago the shaft-pillars above the adit were robbed to such an extent that the shaft was lost in spite of belated efforts to save it; a huge 'glory hole' on the surface, looking as though a good many thousand tons of ore had been taken from it, marks the site of the caved workings.

It was finally decided to utilize the adit for hauling the ore to the mill and to cut a large underground station in the hanging-wall side of the vein for the erection of the electric hoist and auxiliary equipment that had been at the collar of the shaft. Below the adit, the shaft was in fair condition, although in need of some repairs; there were two hoisting-compartments, 5 by 5 ft., and a manway, 5 ft. by 4 ft. 6 in.; and by swinging a short distance into the hanging wall, as further sinking was done, it has been possible to maintain the shaft at a reasonable cost. The hoist-room is 45 ft. long by 33 ft. wide and is timbered with five-member arches of 18 by 18-in. sawed timber spaced 6 ft. centre to centre. Smaller timbers would serve to hold the ground; the larger were used to ensure durability and avoid replacement. The important factor in first cost is not the expenditure for material, but for labor; and this is little more for 18-in. timbers than for the smaller ones.

The entire floor is concreted. A two-compartment raise was driven at an angle of 27° with the horizontal to accommodate the 1½-in. round hoisting-cables running over 7-ft. sheaves, set on concrete pillars at a point 100 ft. above the level of the adit. This is shown in the accompanying sectional drawing of the underground crushing-plant. The hoist, set on substantial concrete foundations, was built by the Union Iron Works of San Francisco; it is actuated by a 400-hp. General Electric induction motor, which is connected through a flexible steel coupling and a large 16-in. herringbone gear to the hoist-shaft. The brakes and clutches are operated by compressed air and a set of C. R. Welch safety devices automatically applies the brakes in case of over-wind or excess speed. A small Giant duplex compressor independently supplies air for operating the hoist-brakes if the main compressor-plant at the portal is not running. Should the electric current fail at any time, the brakes on the hoist would operate automatically under the influence of heavy counter-

weights. The centre of the 7-ft. drum of the hoist is 127 ft. from the sheave and 120 ft. behind the shaft-timbers. Power is brought to the vicinity of the hoist at 2200 volts and a bank of 125-kw. General Electric and another of three 75-kw. Wagner transformers step the current down to 440, all the underground motors, including those in the crushing-plant and in the various pumping-stations, requiring this voltage.

HAULAGE. In conjunction with the placing of the hoist underground, it was also determined to erect the coarse-crushing plant at the same point. Among the considerations that weighed, a few may be mentioned. The ore originally had been lowered from the hill above in a gravity tram. The portal of the adit, on the other

FIG. 3. SIDE-DUMP ORE-CAR

hand, was somewhat lower than the head of the mill, so that, if the coarse crushing were done outside the mine, elevating and conveying-machinery would be necessary. As it is, the mine-cars, by running on a slight up-grade after leaving the adit, can be dumped directly into the mill-bins. The hoist does the elevating and the amount of handling is reduced to the minimum. Another saving is the decreased time required to load crushed ore as compared with run-of-mine material; this has resulted in a considerable economy in equipment as well as labor. The capacity of the 450-ton storage-bins affords desirable elasticity in hoisting operations, with resultant saving. The design of the bins and the arrangement of the crushers is shown in the accompanying illustration, Fig. 1. The construction throughout is strong and substantial, and should require little expense for maintenance. Concrete is used generously, with reinforcement where needed, for example under the crushers and the floor of the coarse-ore bin. Above the bins are 33-ft. arches similar to those that support the roof of the hoist-station.

Three-ton steel skips made by the Angels Iron Works dump directly into the bin, which holds 300 tons. The gates of this bin are of the finger type, seven individually counter-weighted fingers constituting each gate. One

man operates the two No. 5-D Gates gyratory crushers set to crush through a two-inch ring; they are driven by a 75-hp. General Electric induction motor connected to the line-shafting through a flexible leather coupling. A 10-in. double leather belt with short-centre drive runs one crusher, while for the other a 12-in. six-ply Good-

was discarded as being troublesome and unnecessary.

Loading from the crushed-ore bin is done through four are-type gates, the details of which are shown in the sketch, Fig. 2. A novel feature is the operation of these gates by compressed air in a pivoted cylinder to which the air is brought through short flexible hose connections.

FIG. 1 UNDERGROUND CRUSHING-PLANT

rich Blue-streak is used. One crusher is equipped with a manganese-steel mantle, which has crushed 75,000 tons and is expected to crush 250,000 more, while a solid head of chilled steel on the second was discarded after crushing 75,000 tons. The concaves are made in two sections, the upper, 13 in. long, being made of chilled iron, and the lower six-inch section being of manganese-steel. A traveling grizzly was planned to precede the crusher, but this

The loader operates the gates while standing on a platform on the side of the car opposite the chute. A hinged lip balanced by a counter-weight is available in an emergency to catch possible runs.

The pumps underground are operated by electricity, although several air-pumps are placed at critical points to serve in the event of the failure of electric power. It may be mentioned that the company has some water-

power available as an alternative, so that compressed air may be supplied independently of electric current. On the sixth level, 450 ft. below the adit, a Deming horizontal 6 by 8-in. triplex pump run by a 25-hp. General Electric induction motor raises 150 gal. per minute through a 4-in. column. The mine does not make a great quantity of water and an old drift in which has been built a concrete bulkhead has a capacity sufficient to store the accumulation of 48 hours. A Snow steam-pump, connected with the air-line, can be used if required. From the 16th level, 1834 ft. below the adit, an Aldrich 4 by 10-in. vertical triplex pump relays 100 gal. per minute to the reservoirs on the sixth level, while a smaller pump, of

circulation and improve ventilation. The company's policy is to make conditions comfortable for its men, but at the same time it appreciates thoroughly the good influence of desirable conditions on operating account as a result of increased efficiency of its employees.

MINING METHODS. The stations on the lower levels are 10 ft. high, 20 ft. wide, and run back 45 ft. Except for a brow-set there is no timbering; this speaks well for the character of the rock of the hanging wall. The ore-chutes, or skip-pockets, with a capacity of 225 tons, are made by raising in solid rock from a point 50 ft. below the floor of the station. The front of the pocket is 28 in. behind the shaft-timbers at the bottom, and is vertical.

FIG. 2. ARC-GATE OPERATED BY COMPRESSED AIR

similar manufacture and type, provides for the water made between the 16th and 18th levels.

On the 18th level at the shaft-station there is installed a Sirocco fan, or blower, with a capacity of 30,000 cu. ft. per minute, run by a 50-hp. Westinghouse induction motor. The mine had always been warm, and when the lower levels were opened this condition became more marked. The blower was placed at the back of the station and a light wall was built to separate the station from the hanging-wall drifts, north and south. The intake of the fan is on the station side of the wall, where fresh air from the down-cast shaft prevails; the outlet enters the drifts on the opposite side of the wall. The machine therefore acts both as a suction-fan and as a blower, the result being a decided improvement in the atmosphere of all the workings. A raise at the north end of the mine, now partly completed, is to be equipped, when finished, with another fan, to further stimulate

The steel gates are operated by compressed air and the chute-lips are folded up each time a skip is loaded. Just above the pocket for ore, and separated from it by a pillar of solid rock, is a smaller one for waste. The grizzly over the ore-chute is novel. It is 12 by 10 ft. in area and is composed of old stamp-stems, spaced 8 in. apart and laid 3 ft. below the level of the track. The large size permits as many as eight or ten cars to be dumped at once, so that tramping need not be obstructed, while the car-men are breaking the large pieces. One-ton side-dump cars of the cradle-type, manufactured by the Angels Iron Works, run on tracks on either side of the grizzly. This car, shown in Fig. 3, is highly esteemed at the Shawmut. It is simple in construction and easily and safely operated. Large rocks cannot jam in it and there are no gates, hooks, or levers to get out of order. It is substantially built, has roller-bearings, and seems to be an ideal car for the requirements at this mine.

For drilling in development work and in shrinkage stopes the Ingersoll 148 and 248 machines and a few Waugh 'Dreadnaughts' are used. Ingersoll stopers, type 'C-11, are preferred for raising and for stoping in the schist ore, while Ingersoll 'Jackhammers' are used for plugging and similar work. A central shop near the station on the 16th level has been established, where crippled drills are brought for repair and adjustment. Judging from several thousand holes that have been punched in solid rock, a drill does not leave this shop until its efficiency has been demonstrated by actual test. Saws, axes, and hammers also come here for repair.

During the latter part of 1919 a number of changes were made in the methods of mining. Formerly, when the heavy sulphide orebodies were worked by the ordinary square-set and fill methods, huge blocks of ore, often including lenticular masses, broke away and crushed the timbers beneath them. Bulk-heading of every alternate set was tried, but even then the pressure was so great as to completely close the working-floor, breaking or driving the timber down into the filling, so that if recovered at all the ore was obtained slowly and at great expense. Accordingly a system of top-slicing first was tried experimentally and then applied successfully in places where the level above had been mined and the old fill lay above the block to be stoped. Untimbered chute-raises, 4 by 7 ft., at 50-ft. intervals, in the hanging-wall side of the vein, were run through the ore to be removed. Mining was commenced at the point nearest the shaft just beneath the old fill on the upper level. A cut was taken immediately on the hanging wall and run to the opposite end of the shoot, being timbered with light sets sufficiently strong to hold for a short time. The next step was to retreat from the extreme end, taking the remainder of the vein as far as the foot-wall, the only support being occasional stulls with a large head-board to protect the miners. As soon as the timbers in the completed slice begin to take weight they are blasted, thus allowing the mat of old timber and overlying 'gob' to come down to the floor-level. Having reached the starting point, the next slice below is taken in exactly the same way. As the stope is carried down, a manway, above the chute-raise, is lagged and kept open to afford communication with the upper level. This system proved to be much less expensive, less dangerous, and more rapid than the old square-set procedure.

For work in the lower levels also a method of shrinkage stoping has been adopted, some features of which are of interest. Chute-mouths are inserted at intervals of 10 ft., centre to centre; they are 3 by 4 ft. in the clear, constructed of 3 by 12-in. plank. The purpose of this close spacing of the chutes is to maintain an approximately level, rather than a wave-like, top when drawing the stope, so that wall-rock and waste will follow uniformly with the minimum amount of mixing with the ore. Cribbed manways, at intervals, are advanced with the stope, which when once started must be pushed rapidly to prevent loosening of the ore overhead. This is one of the essential points on which the success of the scheme depends. When the stope has advanced to within 30 ft.

of the upper levels, raises are driven through at intervals of 40 ft. and the pillars are blasted in succession, beginning at the end of the stope farthest removed from the shaft, thus allowing the old filling from above to run down and follow the ore as drawing proceeds.

Stopes are worked so that the unmined portion of the vein forms an arch, which lessens the possibility of falling ground; where the stope is more than 100 ft. long a double arch may be established. The middle pillar rests upon broken ore until the crown on each side is advanced 20 ft., after which the pillar is blasted and new arches are started. The distance between levels is 200 ft., but below the 19th this interval is to be increased to 300 feet.

In the quartz orebodies, on the north side of the shaft, a shrinkage method with some modification has been introduced. A series of grizzly chambers 25 ft. above the sill, lagged on the hanging-wall side of the vein for the protection of the workmen, enables the breaking of the ore to shoveling size before it enters the adjacent chute. Above the chambers the work is done as in the stopes just described.

In the most recent development work, on the lower levels, laterals or hanging-wall drifts are driven 15 ft. from, and parallel to, the vein instead of following the ore. Cross-cuts at irregular intervals are then driven to the lode itself. Experience has shown that timbering in a drift on the vein will be replaced at least twice and frequently three times before the ore is mined; and since this kind of work is particularly slow and expensive there is obvious economy in placing the laterals at a reasonable distance in the wall, where any timbers that may be required will last as long as the ground must be kept open.

The hanging wall is invariably good, but the foot-wall generally gives trouble on account of a layer of gouge material, underlying the talc and dolomite that forms the immediate foot-wall. As soon as the wall is exposed, the gouge swells, cracks the dolomite where it is less than 15 or 20 ft. thick, and exerts such a pressure within a short time that no timber, apparently, is able to withstand it, although it seems that after proceeding to a certain point this swelling ceases and the excessive pressure is abated. Fortunately the swelling is not sufficient to close up a stope, so that there is always a passage for the ore in shrinkage operations, even after a considerable period has elapsed. The appreciation of this fact obviously was fundamental in the development of the mining practice.

The ore from the underground crushing-plant is hauled through the adit in trains of two 6½-ton side-dump cars with 30-in. gauge, 300 tons being delivered in an eight-hour shift. The locomotive was built by the Moore & Scott Iron Works of San Francisco and is propelled by two 30-hp. General Electric direct-current motors, one of which is geared to each axle. Current, supplied from an overhead trolley-wire, is converted from alternating to direct by a General Electric motor-generator set at the portal of the adit. The motor is 60 hp., induction type, and the generator operates at 1200 r.p.m., producing 145 amperes at 250 volts.

COSTS. The following figures include the operations during 1919 and indicate the results obtained. It should be remembered that at that time the efficiency of mine labor everywhere, as indicated by the output per man, was low; the miner was not producing at the rate of a few years before.

	Tons of ore
Per man in stopes.....	4.60
Per man on development.....	3.19
Per man underground.....	3.84
Per mine employee (including surface-men).....	3.25
Per drill-shift in stopes.....	28.09
Per drill-shift on development.....	5.49
Per drill-shift (total).....	21.18
Per mine employee (including surface-men).....	Tons ore and waste 3.30

An analysis of the mining cost for the operating period of 1919, during which time the average monthly tonnage was 12,759, is shown below, the details being given for the purpose of interesting comparison.

Tabulated Costs				
Development, direct	Labor	Supplies	Power	Total
Miners.....	\$0.094	\$0.005	\$0.014	\$0.113

Sodium Sulphate

There is a demand in Sweden for sodium sulphate, the paper manufacturers generally being in need of supplies. If American manufacturers of chemicals can promptly satisfy the present demand at reasonable prices a steady market will be assured, according to the U. S. Department of Commerce. The Swedish Paper Mills Association of Stockholm uses on an average 40,000 tons of sodium sulphate per year, and the manufacturing director states that orders will undoubtedly be forthcoming as soon as sure sources of supplies are found.

Wood-pulp for paper manufacture is likewise an important and flourishing Swedish industry, its future being assured by the vast timber supply of the country. In 1919 there were 807,761 tons of wood-pulp exported from Sweden, the value of which was \$13,649,000. The wood-pulp industry is likewise in need of a steady supply of sodium sulphate, the home manufacture being by no means sufficient to meet the demand.

The Flotation of Graphite

Much interest has been shown in the last year or two in the possibilities of oil-flotation for the concentration of graphite ores, and it has been demonstrated that by this system flake graphite can be treated both cheaply and efficiently, says the 'Canadian Mining Journal'. The avoidance of the preliminary drying of the ore, necessary in all methods of dry concentration and in surface-tension or film flotation, is an important consideration from the standpoints of expense and mill-capacity. Additional features are, that a much smaller mill building, involving less initial expenditure, is required to treat an equal tonnage of ore as compared with dry concentration; that there are fewer machines and appliances requiring constant attention and repairs, and that a smaller force of men is required for operation of the plant. A number of graphite mills in Alabama are employing oil-flotation machines of one type or another at the present time, and the system has also been applied successfully to Pennsylvanian ore. In both cases, the ore treated is of relatively low grade, carrying only 3 to 5% of graphite. Oil-flotation has also been adopted by the American Graphite Co., in New York, and is reported to be giving satisfaction. The New York ore is similar in its general characteristics—hardness, texture, and associated minerals—to the Canadian graphitic-gneiss ore. A number of tests with oil-flotation have lately been made on Canadian ores, and a Callow plant was installed in August 1914 at one of the mines in the Buckingham district. Unfortunately, however, the mill was destroyed by fire before the system had had an opportunity of being properly tried out. Three Canadian mills have since been equipped with this system of oil-flotation.

THE engineer of today who wants the latest thing in surveying instruments at a thousand of the company's dollars per transit often fails to realize what really good work can often be done with inferior instruments, or even with no instruments at all of modern design. The ancient Egyptians certainly did not have the modern transit and spirit-level, nor even the science of trigonometry, yet as a record of their achievement it is stated "the highest pitch of accuracy on the large scale was reached under Khufu in the IVth dynasty; his pyramid had an error of less than 0.6 of an inch on its side of 9069 inches, or 1 in 15,000, and its corners were square to 12 seconds. A change of temperature during a day would make larger errors than this in a measuring-rod. The accuracy of levelling and of finish of the stone is on a par with this; joints over six feet long are straight to a hundredth of an inch. . . . In smaller work, a beautiful sarcophagus of Senuser II, which is ground flat on the sides with a mat finish like ground glass, has only about a two-hundredth of an inch error of flatness and parallelism of the sides." This degree of accuracy would not be expected today in works of the same type and we can only speculate as to how it was accomplished with the inferior tools of that time.

Fighting Mine-Fires

By H. J. RAHILLY

*The mining industry, like all other industries, has to guard against the possibility of fire, which, in the case of a fire underground, is apt to be more serious than a surface fire, both as to personal injury and financial loss. In combating a mine-fire the handling of the gas is generally a much bigger problem than the actual putting out of the fire.

Butte, like most mining districts, has had several mine-fires in the past, and today there are several mines fighting fire in districts that are walled off by concrete stoppings (bulkheads).

The chief causes of such fires are:

1. Defective electrical equipment.
2. Incendiarism or carelessness.
3. Spontaneous combustion.

The use of electricity in the mines for running pumps, fans, motors, electric lights, shaft and signal bells has made it necessary to use wire covered with a good grade of insulation and cables insulated with a lead or asbestos covering. Care must be taken to see that these wires are placed where they will not be hit or injured, and in the case of trolley-wires, to see that the hangers are well insulated. On account of the acid water in most of our Butte mines, ordinary insulation is soon eaten away if the wires are in a wet place and frequent inspection is necessary, so that a bare wire will not come in contact with some inflammable material.

Incendiarism or carelessness has been the cause of numerous small fires, but these have been discovered before they became serious and were extinguished.

The other cause of mine-fires, spontaneous combustion, has been the origin of most of our large fires. Inflammable materials, such as tarry ropes, canvas, dry timber, manure, and hay have been left in the gob some years ago, and, owing to ground movement and decomposition, heat has been generated sufficient to start a fire, also the heat resulting from the oxidation of the fine sulphide ore is sometimes sufficient to set fire to the timber. These fires are serious because they generally occur in parts of the mine that have been mined out, caved, and are inaccessible.

At the present time, the places that are most susceptible to fire, such as working shafts, stations, cross-cuts and drifts having high-tension wires in them, motor, fan, and transformer stations, oil-houses, and powder-magazines are covered with 'gunite', or cement mortar, so as to make it difficult for a fire to start.

Concrete stoppings (bulkheads) with iron doors are placed near the shafts on each level throughout the different mines so that should a fire start it can be isolated to some extent.

When a fire is discovered, inspection trips are made with oxygen apparatus, if necessary, to locate, if possible, the extent and exact location of the fire. This is not always possible because sometimes the fire is in old worked-out stopes that are inaccessible. At the same time that inspection trips are being made to locate the fire, the directions of the air-currents are noted and steps are taken to control the air, so as to keep the gas from traveling to other parts of the mine. All operating shafts are down-cast, and the ventilation underground is so controlled that the gas from the known fire areas is disposed of, through up-cast shafts without passing through the active working-places.

If the territory affected is small and easily accessible, hose-lines are played upon the fire until it is put out; if, on the other hand, it is impossible to get to the active fire, concrete stoppings are started so as to completely isolate the territory affected, and to keep as much air from the burning country as possible. After this has been done cross-cuts or diamond-drill holes are put in from different places, on levels above where the fire exists, and water is then turned into the burning country through these cross-cuts or drill-holes.

In handling a fire in a Butte mine, three principal gases are encountered.

1. CARBON MONOXIDE. This gas is produced by the fire burning in an atmosphere where there is insufficient oxygen for complete combustion. This gas is lighter than air, is colorless and odorless, and has no effect on a lighted candle or carbide lamp. Carbon monoxide is the gas that forms a blue flame above a coal-fire, and in the impure state, as found in the mines, it has a characteristic odor and is known locally as 'sweet gas'. Carbon monoxide, even in small quantities, is very poisonous to the human system. Its presence underground can easily be detected by the use of small birds or mice, these animals being more susceptible to the gas than is a person.

In Technical Paper No. 11, George A. Burrell, of the U. S. Bureau of Mines, gives the following table showing the relative susceptibilities of mice and canaries to carbon monoxide poisoning:

Effect of CO on Mice and Canaries			
Mice		Canaries	
CO. %	Effect	CO. %	Effect
0.16	Very slight distress at end of hour.	0.09	Very slight distress at end of hour.
0.2	Distress in 8 minutes; partial collapse in 15 minutes.	0.12	Weaker at end of hour than after exposure to 0.09%.
0.31	Distress in 4 minutes; collapse in 7½ minutes; lost muscular power in 35 minutes.	0.15	Distress in 3 minutes; fell from perch in 18 minutes.
0.46	Distress in 2 minutes; collapse in 4 minutes.	0.20	Distress in 1½ minutes; fell from perch in 5 minutes.
0.57	Distress in 1 minute; collapse in 2 minutes; muscular power lost in 7 minutes; death in 16 minutes.	0.29	Fell from perch in 2½ minutes.
0.77	Distress in 1 minute; muscular power lost in 6½ minutes; death in 12½ minutes.		

*From 'The Anode', the monthly publication of the Anaconda Copper Mining Co.

Also the following giving the 'Relative Susceptibilities of Men and Birds'.

"In order to determine for himself the relative susceptibility of men and birds to the action of carbon monoxide, the author performed the following experiment:

"A gas-tight chamber, having a capacity of 80 cubic feet, was constructed. Into this chamber sufficient carbon monoxide was introduced to produce an atmosphere containing 0.25% of the latter. The author entered this atmosphere, taking with him canary birds and pigeons. The canary birds evinced distress in one minute and fell

These drifts and cross-cuts were opened up sufficiently to allow pipe-lines to be put to the tops of the different raises or, if this necessitated considerable labor, diamond-drill holes were run to the raises that were inaccessible. Six-inch extra-heavy cast-iron pipe conveys the tailing down the shafts to the various levels where 4-in. lateral pipes run off to the stopes. Where diamond-drilling has been resorted to, the holes are 'fanned out' to cover the entire stope. These drill-holes are $2\frac{1}{2}$ inches in diameter and are cased with 2-in. extra-heavy pipe, these casing-pipes being connected by means of short pieces of fire hose on the 4-in. lateral lines.

On the level below, as shown on Map No. 2, the concrete stoppings have been reinforced so that they are about five feet thick, and are provided with two 2-in. copper drain-pipes in each stopping. Valves are put on these 2-in. pipes and the water from the tailing that is put in on the level above is drained off. This water carries copper in the form of copper sulphate and is pumped to the surface, where the copper is recovered at the precipitating plant.

The tailing, which is the finely-ground waste material from the flotation process, averages about 600 gal. of water per ton of solid. Before entering the mine it passes over a weir that is equipped with a hydro-

from their perches in three minutes. The pigeons only showed slight signs of distress in 11 minutes. The author remained in the atmosphere for 20 minutes, and at the end of that time only suffered a slight headache, although later he became ill. The illness lasted several hours and was accompanied by nausea and headache.

"The experiment shows that small birds are much more susceptible to the action of carbon monoxide than are men, and demonstrates the desirability of using small birds, such as canaries, rather than larger ones, such as pigeons."

2. CARBON DI-OXIDE. This gas is colorless and odorless and will extinguish a lighted candle or carbide lamp. It is formed by the burning of the timber and is dangerous in that it replaces the oxygen in the air, but it has no poisonous effect on the human system.

3. SULPHUR DI-OXIDE. This gas has a very characteristic odor, like that of smelter smoke and when breathed causes a very disagreeable and irritating feeling in the throat. This gas is formed from the burning sulphur in the broken ore.

For the past two years mill-tailing has been used to reclaim one of the fire-zones, which had been sealed with concrete stoppings at the time of the fire. Map No. 1 shows a level, the shaded portion representing the country that was sealed off and which subsequently has been filled.

chronograph, which mechanically records the volume of water and solid passing; samples are taken every half-hour and from these, calculations are made as to the amount of solid and water entering the mine. Several stopes are kept available for filling at all times and an account is kept of the amount of tailing going to each. All water pumped from the mine passes over a weir also equipped with a hydro-chronograph and, by means of this, account is kept of the water that is drained from the stoppings. In this way no large reservoirs of water are allowed to accumulate in the stopes.

In opening up a level so as to introduce the tailing, either new cross-cuts are driven around the old workings

from which drill-holes or short cross-cuts are run to the fire-stopes, or the old workings are repaired. In case the latter method is pursued, air-locks are built in front of the concrete stoppings, consisting of two brattices built about 15 to 20 ft. apart and provided with tight doors.

These brattices are made of inch boards covered with metal lath and coated with gunite or they are made of burlap over which chicken-wire, with inch openings, has been stretched, and then gunited. A small Sirocco fan, either No. 2½, No. 3½, or No. 4 is placed outside these two brattices in a place that has free access to fresh air. The fan-pipe, which is 12 or 16 inches in diameter, is a canvas pipe and is carried through the two brattices above the doors. The concrete stopping inside is then blasted open and the work of repairing or putting pipe through the drift or cross-cut to the stopes is started.

The fan is thus used to hold back the gases that are in the fire-area and make it possible for the men to work in fresh air. Much of the preliminary work of repairing drifts, guniting stoppings, and opening up new places is performed with oxygen apparatus. In some places, where the ground is badly fractured and broken, considerable difficulty is experienced in keeping the tailing from leaking through the rock. In these places the loose ground is removed and several coats of gunite applied.

The tailing was first put into the lowest levels of the fire-zone and built up from this foundation. From 2500 to 3000 tons is introduced each week, the process being a continuous one. Up to the present time nearly 300,000 tons of tailing has been used.

Ore-Reserves of the Rand

"With the publication of the last of the annual balance-sheets and reports it becomes possible to give a complete table of the ore-reserves of the whole Witwatersrand—the stock-in-trade of the industry upon which productive operations are dependent," says 'The South African Mining and Engineering Journal'. "The features of the year's activities on the Rand in regard to productive operations—that is to say, the incidence of the gold premium and of rising costs—are reflected in the development figures. It is to be noted that some companies show the additional tonnage which is represented in the ore-reserves with gold at a definite premium (in the attached schedule the General Mining & Finance Corporation shows additional reserves in respect of a premium of 30%), whilst other companies take no cognizance of the extra price.

"At the end of 1918 the payable ore-reserves of Witwatersrand mines were estimated at ninety million tons, which was approximately a decline of six million tons compared with the estimates of a year previously. The outstanding feature of the year's work on the Witwatersrand and in regard to ore-reserves during 1918 was that, although development was 'speeded up' on the Far East Rand, the increase in working expenditure compelled the elimination of millions of tons of low-grade ore from the estimates of payable reserves. Since the outbreak of

hostilities in Europe and up to the end of 1918, the costs of operation on the Rand increased by the equivalent of 1½ dwt. per ton, and in consequence large areas formerly reckoned profitable were ruled below the pay-limit, whilst at the same time there was a general increase in the value of 'pay' ore on account of the rise in costs. In December 1918, working costs were 21s. 7d. per ton, and by December 1919 they had risen to 25s. 6d. This is a very substantial advance in the costs of operation, and under normal circumstances there would have had to be a further large shrinkage in the payable reserves of the mines as at the end of last year due to the raising of the pay-limit. The gold premium, however, luckily came to the rescue. But for this fortunate circumstance the payable ore-reserves of the Main Reef series would have contracted to a figure which would have greatly impaired the credit and stability of the industry. For ore-reserves are the stock-in-trade of the Rand, and a marked diminution would have been highly detrimental to the prosperity of the whole Union. On the old basis of gold-values an average working cost of 25s. 6d. per ton meant that the mines had to recover not less than 6 dwt. per ton milled in order to pay expenses. Leaving aside any question of profit or dividend to shareholders, 6 dwt. per ton had to be yielded in order to meet the routine of normal expenditure. At the end of 1918 there were 13 companies with 'payable' ore-reserves of a lesser value than 6 dwt. per ton.

"With costs at their present level an average value of 6½ dwt. in the blocks is required to yield profits. It is to be observed that 25 companies with ore-reserves amounting in the aggregate to 38½ million tons, give values of 6½ dwt. or less per ton.

"The total payable tonnage in the mines of the Rand at the end of last year was approximately 91,500,000 tons, or an increase of about 2½ million tons on the figures for a year ago."

A RECENT visitor to Colombia says: "The extremely liberal mining-laws render it possible to select and hold enormous concessions at a nominal cost, but at the same time this facility has the effect of enabling the owners to hold on to their mines until they believe that they are fair if not generous terms. Many large concessions have been held for years, and, in some cases, for generations. A thorough knowledge of dealing with the natives is as important as technical judgment in acquiring Colombian mines; above all, any expedition sent out to investigate Colombian properties, whether mines or otherwise, must show no signs of haste; neither must any anxiety be exhibited to close a deal. These are the two principal points that have often been neglected and their neglect has held back the development of Colombian mines."

WHEN A HOLE has misfired an effort should be made as soon as possible to have it fired. Holes loaded with explosives are dangerous. If it is not practical to fire the hole at once, it is better to place a plug in the hole or mark it in some way so that the miners will be notified of the danger.

Labor the Holder of the Nation's Wealth and Income—III

By W. R. INGALLS

*I have not in this or previous essays on the same subject propounded any new theory, but rather have I merely illustrated the practical working of things according to the theories of such economists as Jevons and General Walker. Even my statistical reasoning simply follows what has previously been done by Mallock, although, with the benefit of recent and more detailed statistics for the United States, I have been able to make a more minute analysis of the division of income.

One of the outstanding features in all of these studies is the tremendous part that mind has played in the increment of national income, with the constant reversion of the major part of that increment to the multitude of wage-earners. I may usefully cite some homely illustrations of this from the metal-mining industry, one of the great basic industries, with which I am especially familiar and in which I have played some part.

One of the greatest and most profitable branches of metal-mining is copper mining. The gross income of the profitable mines (nearly all were profitable) in 1916 was about \$555,000,000 and their net income (but not their dividends or their earnings really applicable to dividends) was about \$271,000,000. It was a year of phenomenally high prices and extraordinary earnings. However, the bulk of this great production was derived from mines that would not have existed in 1916 as mines at all had it not been for improvements in the arts of mining and metallurgy effected within the previous ten years. As recently as 1906 so astute and distinguished an authority as J. R. Finlay viewed the Anaconda mines as decadent owing to the impoverishment of their ores, yet since then we have seen them ascend to greater production and profit than ever before. This was due distinctly and entirely to the most brilliant exhibition of mind that has ever been witnessed in any industry in modern times.

In 1906 the vast deposits of copper ore that are now the source of a major part of the American production, classed generically as the 'porphyry' mines, were useless to anybody. They had been known for decades, they were practically free to acquisition by anybody, but their copper contents were too small to be extractable. Some engineers who were then poor men conceived their exploitation by new methods. In order to carry them out they had to tempt investors to supply fabulous sums of money, as much as \$10,000,000, for the equipment of a single mine. These investors had to wait years for any return, during which it was uncertain whether they might not lose all the money they had risked, for they were adventuring in an untried field.

These great increases in the national income were made by mind, with the aid of capital, without which the mines

of Butte would today have been nearly dead and the 'porphyries' would not have been born. They were in no wise at the expense of wage-earners, nor have the latter any claim upon them beyond that which economic law gives them, and what it does give they have received. Their ability to work has been greatly increased and they have got higher wages for their work. Thirty years ago the common rate of wages for miners in the Rocky Mountains was 30c. an hour. During the '90s it rose to 37c. in Butte. During the next decade it rose to 47c. In 1916 it was 60 and 65c. During the last ten years wages have been paid largely on a sliding scale, according to the price of copper, whereby the wage-earner has participated in the increased profits of the employing companies. The Butte scale governs, to a more or less extent, the wages in other districts, with modifications according to living conditions, character of work, etc. Labor's great gain in mining has been due to mind, aided by capital, enabling it to produce more. Without mind and capital it would not have had any gain. With mind and capital both of them profited greatly, but labor profited most.

Probably the full working power of the nation is never employed at any one time. According to the U. S. Census of Manufacturers the average number of wage-earners in the factories in 1914 was 7,036,337, and the general computations are made upon that basis. The maximum number in any one month was 7,242,752 and the minimum 6,640,284. The minimum was 91.7% of the maximum. The average was about 97%. The figures for 1914 show a high degree of uniformity of employment. However, the maximum does not necessarily represent the total number of factory workers. At any time there is a certain number who are idle from choice, from physical incapacity, or from inability to obtain work in their own trade and habitat. The amount of this surplus, which, of course, must derive support from its several industries, is necessarily conjectural. If I assume that 90% of the factory workers are employed on the average I shall not perhaps be very far out of the way.

Similar conditions prevail in other districts. The builders suffer from a good deal of lost time. Coal miners, according to the statistics of the U. S. Geological Survey, work habitually only from 200 to 235 days out of the 305 to 310 possible in the year. Manifestly coal mining is a badly organized industry.* In 1917 the

*This was written in the early part of 1919. On November 1 began the general coal strike for a 30-hour week, and the public attention was drawn to the badly functioning nature of the bituminous coal mining industry. The prime trouble is deficiency in railway service, which perhaps results from antecedent economic evils. However, as conditions are now, and for many years have been, there are either more

*From 'The Annalist', of September 27, 1920.

average number of railroad employees, according to the report of the Railway Wage Commission, was 1,740,479, but in December of that year the number was 1,939,399.

Unemployment is a dreadful thing. There are some occupations that are necessarily seasonal, in which the wage-earner is expected to safeguard himself. There are others in which idleness results from industrial causes quite beyond his control, from causes beyond his employers' control. Some of our industries function badly, the mining of bituminous coal, for example. On the whole, however, manufacturing in the United States, if we may judge from the latest complete statistics (those of five years ago), shows no great variation in the number of persons employed month by month. But even so there is need for greater steadiness. The means for attaining it are not what the wage-earners think. They are not concessions to be wrested from the employing class, and yet it is just that class that is responsible, owing to its being the directing class. The wage-earners should not say: "Give us what you are keeping from us", but rather: "You are poor leaders; think how to direct us better." The means are purely economic and consist mainly in improving the transparency of industry, which will have the certain effect of minimizing ups and downs and maintaining a steadier course.

In comparing the incomes received by different classes of people it is obviously essential to consider the difference in living conditions, not only among occupations, but also among groups of people engaged in the same occupation. Thus the farm laborer neither requires so many things, nor do those that he does require cost him so much as the urban laborer. Consequently he is by no means so badly off as the statistics indicate. I computed in 1918 that a hired farm foreman who was receiving a cash wage of \$50 per month and house rent and supplies that made his real wage \$80 per month would have been obliged to earn at least \$94 in the near-by city to be equally well off, and more likely would have had to earn \$100. Miners are paid less in the copper mines of Michigan than in those of Montana, for it costs less to live there. Michigan miners attracted to Montana by the higher wages have found that they suffered diminution of net income and have returned to Michigan.

There are three elements in the production of wealth, namely, Labor, Capital, and Mind. In the controversy over the division of produce the latter two are commonly associated as the antagonist of Labor. The interests of Capital and Mind are, no doubt, the same, or about the same. However, there is a great difference in their position. Capital is to a considerable extent the accumulation of previous generations, inherited by the present

coal miners than are needed or else the production of coal could be greatly increased if the railways could carry it. There is manifestly a bad industrial situation here that should be corrected in some way, and probably could be corrected by leaders capable of thinking in terms of the industry as a whole. The coal miners themselves are the victims of bad leadership. Nothing that they can do by regulation of hours or rates of wages will improve their situation. The trouble is in the high command, not in the lower ranks.

possessors. Mind, on the other hand, springs directly from the ranks of Labor to a considerable extent. Especially in the United States it is always the case that a large proportion of the great directing minds are men of humble origin who have become capitalists by their own efforts.

Grouping Capital and Mind as the employing class, however, there is nobody who is averse from the promotion of the welfare of labor. It is merely a question of how much Labor, with the aid of Capital and Mind, can produce. There are certain demands of labor that the employing class should recognize in the common interest, and if it has been inattentive to them in the past that is ascribable to its own blindness. Working-places should be made safe and sanitary, representations of the workers respecting conditions should be considered, education should be encouraged, friendly attention should be given to the improvement of living conditions, including the checking of rapacity by landlords and tradesmen. All of these things should be done in the interest of enhancing efficiency and increasing production. Old-age pensions, insurance and maintenance during sickness are desirable, but can, of course, be paid for in no way except out of production, that is, by the wage-earner himself, and when done through the medium of taxation there is the assumption that the wage-earner's own thrift cannot be relied upon.

There are two specific demands of labor (other than the general demand for a larger share of the produce of industry) that are distinctly economic rather than sociological. One of these is for more considerate treatment as human beings, as for example in the shops of half a century ago, when the boss worked with his few men; even as squads of carpenters work in the country today. The realization of that desire would put the world back to the scale of living of fifty years ago. Men would not earn so much and they would not have so much. The old relationship has been sacrificed to Directing Mind, for the sake of the benefit of organization, and Labor has been paid for the sacrifice. It cannot eat its cake and have it too. Any such idea spells Bolshevism.

The other demand is expressed in two ways, namely, the right to work and the right to a wage commensurate with a decent standard of living. It may be flippantly represented that no man is deprived of the right to work, that any man may go into the fields and forests and find work to do, but practically he cannot, and the right to work means really the right of a man to work at his own trade. Associated with this is the minimum wage, which results from the confusion between money-wages and goods-wages. Neither the State nor the employing class can guarantee any standard of living. That depends solely upon what the wage-earners themselves produce.

The real gauge of the production of a country is not what is measured by dollars, but rather is what is measured by quantities. Unfortunately, reference is commonly made to the former owing to its being easier. The accompanying table shows the production of the principal commodities in the United States in 1916-1918 and enables some quantitative comparisons to be made.

**Quantitative Comparison of Production of Principal Commodities in the
United States in 1916-'17-'18**

This table is compiled from the reports of the U. S. Department of Agriculture and the U. S. Geological Survey, the figures being reduced to the uniform basis of the ton of 2000 lb. and the following factors being used for conversions: Lumber, 1000 ft. b.m. = 2000 lb. Cotton, one bale = 500 lb. Corn 1 bu. = 56 lb. Wheat, 1 bu. = 60 lb. Oats, 1 bu. = 32 lb. Barley, 1 bu. = 45 lb. Rye, 1 bu. = 56 lb. Potatoes, 1 bu. = 60 lb. Apples, 1 bu. = 50 lb. Milk, 1 gal. = 8 lb. Poultry, average 4 lb. per head. Eggs, 1 doz. = 1.2 lb. Cement, 1 bbl. = 376 lb. Petroleum, 1 bbl. = 280 lb. While these factors may introduce some errors, the resulting figures are near enough.

Building Material	1916	1918
Lumber	79,614,502	65,520,000
Cement	17,205,985	13,363,352
Sand and gravel	89,091,732	61,802,694
Stone	91,831,000	80,000,000
Lime	4,073,433	3,028,000
Total	281,816,652	223,714,046
Fibres		
Cotton	3,184,250	2,925,000
Wool	144,295	140,960
Total	3,328,545	3,065,960
Cereals		
Corn	72,330,748	72,318,792
Wheat	19,196,480	27,513,000
Oats	20,027,372	24,613,699
Barley	4,070,857	5,768,437
Rye	1,326,724	2,494,884
Total	116,952,181	132,708,812
Other Agricultural		
Meat	10,384,250	11,683,000
Potatoes	8,608,590	11,703,030
Apples	10,229,150	9,888,000
Milk	32,012,000	33,716,000
Eggs	1,188,000	1,152,600
Poultry	1,134,000	1,178,000
Sugar	303,900	263,450
Tobacco	576,639	670,010
Total	64,436,529	70,234,090
Metals		
Iron	39,434,797	38,820,000
Copper	971,388	934,975
Zinc	680,018	525,122
Lead	592,241	550,729
Total	41,678,444	40,830,826
Fuels		
Coal—hard	87,578,493	98,826,084
Coal—soft	502,519,682	585,883,000
Petroleum	42,107,402	49,018,340
Total	632,205,577	733,727,424
Other Minerals		
Gypsum	2,757,770	2,056,462
Phosphate rock	2,220,271	2,789,651
Salt	6,362,906	7,238,744
Clay	2,932,590	2,810,000
Total	14,273,497	14,894,857
Summary		
Building material	281,816,652	223,714,046
Textiles	3,328,545	3,065,960
Cereals	116,952,181	132,708,812
Other agricultural	64,436,529	70,234,090
Metals	41,678,444	40,830,826
Fuels	632,205,577	733,727,424
Other minerals	14,273,497	14,894,857
Grand total	1,154,691,425	1,219,176,015
The hay crop	110,992,000	89,833,000

The table embraces the principal basic commodities. The chief omissions are beans, fish, vegetables used green or canned, fruits other than apples, flax, hops, hides, and sundry mineral products. However, the grand total comes pretty near to being the grand total of all the raw products of the United States.

These production figures agree closely with those of the Interstate Commerce Commission for the total tonnage of freight originating on the railways of the country, as follows:

Year	Tons
1916	1,202,000,000
1917	1,264,018,725
1918	1,229,116,759

Previous to 1916 the railway figures were given for fiscal years, which are not truly comparative. However, the figure for the fiscal year ended June 30, 1914, representing the twelve months immediately preceding the War, may be viewed instructively. In that year the total tonnage of freight originating on the railways was 1,000,460,330.

The railway figures should not correspond exactly with the production figures. Considerable freight is moved over rivers, canals, and highways. Many products, for example hay, are never moved off the property where raised. On the other hand, the railway statistics to some extent count the same products twice, for example, iron ore first and then the pig-iron made from it. Nevertheless, it appears that they are a fairly reliable index.

Returning to the production figures, it is manifest that they also must be viewed with qualifications. Here also there is duplication. Thus much of the hay and not a little of the cereal crops reappear in meat, poultry, milk, and eggs. Some products may be adulterated.

With such discriminating consideration, therefore, it may be safely deduced that during the three years 1916-'18 the production of building material decreased, the reasons for which are so well known that no further explanation is necessary. Fibres decreased a little. Cereals increased largely, for which again no explanation is necessary. There was also an increase in "other agricultural products", but in the production of hay there was a progressive and large decrease, which was a serious matter. Metals decreased a little, in spite of the strenuous efforts to maintain production. "Other minerals" increased a little, the increase in this case being due especially to salt and to phosphate rock (which may be connected with the agricultural increase). The most noteworthy increase of all was in the fuels.

Now in both cases—agricultural products and fuels—special conditions obtain. In agriculture there is far more elasticity in the capacity of labor than in mining, manufacturing, and other industries. The farmer who with his helper harvests ordinarily twenty tons of hay during the month of July finds no difficulty in mowing and storing thirty tons if an exceptionally good season gives it to him. In 1916 the yield of agricultural products according to my total (including hay) was about twenty-one tons per worker. The increase in the cereals and the decrease in hay in the following years *probably* occurred without there being any material change in the number of workers, and the tons per man *probably* varied a great deal.

It is important to note that whereas the agricultural produce in 1916 was only about 21 tons per worker the output of minerals was nearly 1100 tons per worker. This reflects the difference between a slightly mechanicalized and a highly mechanicalized industry.

The increased production of cereals and fuels was chiefly, perhaps wholly, demanded by conditions of the War—cereals to feed Europe, the fuels for extraordinary war-time movements.

It is sufficiently clear from this reasoning, rough though it be, that the increase in American commodities

from 1916 to 1918 was wholly attributable to those in the production of which there had previously been much lost time. If these be deducted from the grand total it will appear that in all others output was either at a standstill or diminished. In other words, there was a smaller supply of goods to be divided among the people, although the number of people increased, the population of the United States being estimated at 99,027,000 in 1914, 100,725,000 in 1915, 102,431,000 in 1916, and 104,145,000 in 1917. An estimate for 1918 would be about 106,000,000. In spite of the draft of men into the Army and the Navy, the increase in population, together with the employment of women in increasing numbers and the impressment of previous idlers, which probably maintained and possibly increased the working population, the latter was either unable or did not choose to increase production after 1916.

There is thus a good deal of reason to believe that the output of minerals, metals, and manufactures in tons per man declined from 1916 to 1918, and that high wages, instead of being a stimulus to increased production were a direct inspiration toward increased loafing. Many men who previously had to work 48 hours per week in order to get their living worked only 32 hours when they became able to obtain sufficient in that time. It may be conjectured that production would have declined more seriously during this period if managerial efficiency, strained to its utmost, had not offset the slacking by the workers. Even as between the 10-hour day and the 8-hour day in normal times, it is doubtful whether the assertion that workers can (or will) produce as much in eight hours as in ten be not a fallacy. Anyhow, it is a debatable question. All of these conditions deserve more study by the methods of a broad survey than has yet been given to them.

This study, incomplete as it is, reveals certain things that are positive. The workers of the country in 1916 could have added but slightly to their income if they had confiscated the entire share of Capital and Mind in the national produce. Since 1916 Labor as a whole has not benefited, for the national produce has not increased in quantity, on the whole, and a large part of it has been wasted for warfare. We have got along as well as we have only by the use of previous accumulations of goods and failing to do things that are necessary for the comfort of the people, such as improving transportation facilities, adding to housing capacity, etc. Instead of the American people as a whole having risen to a higher plane of living than before the War, they have descended to a lower.

Some classes of labor have profited, to be sure, but that has been wholly at the expense of other classes of labor. The taxpaying classes suffer diminution of net income, but, even so, they retain enough to satisfy all material wants in shelter, clothing, and food. Not so with the less fortunate among the working classes. They are deprived of the full measure of shelter, clothing, and food that is necessary to maintain a high standard of living. The taxpaying class is deprived, in the main, only of the former ability to save, and that in itself is to the disadvantage

of the working classes, for it was just those savings that used to build railways, houses, etc.

It has been shown in this study how wide are the variations in the average income of the working classes. The agricultural worker in 1916 got only \$400. The factory worker, \$675. The railway man, \$886. The metal miner, \$1250. It is impossible to ascertain the average earnings of builders, clerks, and shopkeepers, but probably they were in the superior ranks.

Among the major classes themselves there are wide variations. Thus railway conductors and locomotive-drivers receive high wages, while the track hand gets low wages. Similarly, in the steel industry the metal roller is relatively a plutocrat, while the yard laborer receives only a pittance.

I think that it has been made clear that when a group of workers, like the railway workers, whose uninterrupted service is indispensable to the life of the people, band together, take the people by the throat and exact higher wages, which means the right to command more goods, they do so at the expense of all other workers. When the steel workers say that they demand wages that will afford them a high standard of living, they say in effect that they want to get that for themselves, and do not care what happens to the clerks and factory workers. It will be the realization of this, I think, that will eventually disrupt the American Federation of Labor, just as the Knights of Labor disintegrated in the 'eighties.

That America will become Bolshevik is not to be feared. If any such fear be entertained, the thought that the corporations of the United States are mainly owned by people of moderate incomes, and that about one-third of all our workers are agriculturists will dispel it. A fault in most discussions of this whole subject is the absence of perspective, the appreciation of the huge number of our workers, and how what seems to be only a few dollars for the individual means billions in the aggregate. It has been the purpose of this study to furnish a perspective.

The economic lesson is, of course, simply that there must be more production and less extravagance. In no other way can the standard of living be improved. The idea of increased production cannot be reconciled with the idea of the six-hour day and the five-day week. Increased production can only be expected as the result of more work and harder work; and by improved organization by the captains of industry.

It may be asked: If the return on the capital of the country is relatively so small as has been indicated herein, why is it that some corporations realized such phenomenal profits in 1916? It is precisely those profits upon which the attention of the dissatisfied is focussed and prompt the question why should profits in some cases be as large as the total payroll and the outcry that there is something manifestly unfair in that.

The answer is that such corporations are relatively few and the aggregate of their swollen earnings is relatively small in comparison with the grand total. This may be grasped when it be considered that the dividends of all corporations in 1916 were less than \$4,000,000,000.

But how are the few excessively profitable corpora-

tions to be treated? Suppose there be an industry employing 10,000 men who earn an average of \$1000 per annum. Suppose there be one company in that industry that employs 100 men by virtue of superior management, location, the possession of rich raw material, etc., earns a profit of \$1,000,000, which is 50% on its capital, while all the other concerns in the industry earn from 10% at the maximum down to nothing at all. The rich concern could afford to pay higher wages, but if it did so what would be the situation in the rest of the industry? How would participation in profits work out in such a case and why should participation in profits be granted to persons to whom they were not due, the assumption here being that they were due to managerial excellence? If the men working in the no-profit factories should by the exercise of increased diligence and intelligence produce a profit, the management remaining the same, a participation in it would be reasonable, but that idea is not commonly expressed.

The matter of very great profits is capable of several developments that are more or less sound economically.

1. They may be commandeered by the State as excess profits taxes, the burden of taxation upon the bulk of the people being correspondingly reduced. There is always the danger that such a levy will be made so severe as to destroy incentive, in other words, kill the goose that lays the golden egg. However, within limits, such an equalization of profits may be effected.

2. Increase the transparency of industry, so that competition will tend to reduce excessive profits. Manifestly, if the profits of the industry that I have cited were more equally divided, labor could demand and would get higher wages. I believe that this is the true economic solution of the great problem of the time. Labor would gain and capital would not lose.

3. Exterminate the less efficient concerns in an industry and concentrate production in the big economical corporations, which can afford to pay increased wages. Some of the thoughtful among the labor leaders are supposed to have indorsed such a program, although it means practically nullification of the anti-trust laws. This may be economically defensible, but the idea of putting great industries absolutely into the hands of big corporations co-operating with big labor unions is abhorrent.

I think it is obvious that the second of these thoughts is inherently the soundest, but owing to its abstractness it may not readily be grasped. Yet reflection upon it will show that it holds forth the real remedy for many economic and social evils. It may be suggested that a combination of the first and second would be wise, but I do not think so. Taxation upon consumption is more rational than taxation upon production.

However, any program may lead nowhere if there be absence of understanding of what is to be divided. That which is to be divided is not money, but goods. Taking the industry that I have suggested, and let it be supposed that it was engaged in the manufacture of shoes, elevation of the industrial plane might result in three ways.

1. The 10,000 men engaged in the industry might make

all the shoes necessary by the labor of six hours per day instead of eight and decide to work only six. Then they would have more leisure, but if the time gained were idled away nobody would be any further ahead than he was previously. There would be no increase in the standard of living for anybody.

2. It might be found that instead of 10,000 men being required, 8000 could make all the shoes needed, and 2000 could be diverted to the manufacture of something else that was wanted.

3. The output of shoes might be increased and the surplus sold to some other community in exchange for some of its goods. The second and third are the only ways whereby labor can participate in the profits of industry and benefit therefrom.

ACCORDING to Edwin N. Gunsaulus, U. S. Consul at Singapore, the imports of tin and tin ore into the Straits Settlements during 1918 were 85,000 and 1,059,000 piculs (1 picul = 133½ pounds), respectively, and the exports of tin 925,000 piculs of a value of \$81,546,038, of which the United States took 578,000 piculs of a value of \$51,070,145. For 1917 the imports into the colony of tin and tin ore were 107,000 and 1,240,000 piculs, respectively, and the exports of the refined product 1,076,000 piculs, worth \$66,898,601, of which 392,000 piculs, worth \$24,607,162, was exported to the United States. Although the total exports of tin in 1917 exceeded in quantity those of 1918 by about 151,000 piculs, the value of the 1917 exports was less by \$14,647,437 owing to the exceedingly high prices received for the metal in 1918. The imports of tin into the Straits Settlements, as distinguished from tin ore, represent the output of small smelting plants operated by the Chinese in the Malay States, also shipments from European smelters at Penang, which are almost exclusively for transshipment at Singapore. In addition to the above a small quantity of slab-tin (unrefined) is received from Siam, for transshipment to China. The relative quantity of refined tin imported, compared with tin ore, is small, this being accounted for by the fact that the tin-smelting concerns in Singapore and Penang are in position to handle the ore more advantageously than the average mining company.

THE borax or tincal deposits occurring in Tibet were probably the first borates ever utilized. About 220 tons is exported annually from India, and this, which is practically all obtained from Tibet and Ladakh, is imported across the frontier into the Punjab and United Provinces. Herds of sheep and goats may be met in the Himalayan passes coming down from Tibet in the spring, each carrying two small bags of borax or salt to be bartered for Indian and foreign stores. The material exported from Tibet is obtained from salt lakes which have possibly obtained their borax from volcanic sources. The borax obtained from the Puga valley of Ladakh, Kashmir, is deposited from hot springs associated with sulphur deposits, which are regarded as evidence of waning volcanic action.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

PHELPS DODGE STOPS OPERATIONS ON SACRAMENTO HILL.

KINGMAN.—Development work is in progress on the property of the New Comstock Mining Co. The main shaft is to be continued to a depth of 700 ft., and the vein thoroughly explored to that depth. The mine is being developed at present on the 300 and 400-ft. levels where good bodies of mill-ore have been developed. Operations at the Swansea mine, which were stopped a few months ago by a strike, are again in progress, with 120 men at work. The property is under lease to the operators of the Humboldt smelter, and the ores are being dressed and shipped to that plant. The company is reported to be interested in a project to develop water-power by the construction of a dam at the Bill Williams fork. An important strike of ore is reported on the Tom Reed property, in the east drift of the Aztec mine, about 200 ft. from the west end-line of the American. The drift has been in the orebody for a distance of 60 ft., samples averaging about \$40 in gold, with some higher.

TUCSON.—F. L. Ransome, who is in immediate charge of geological work in the metal-mining districts, under the U. S. Geological Survey, will be at Tucson next month to confer with mining men about a survey of the Papago mining district. He probably will make a preliminary study of the Pima and Papago districts.

TOMBSTONE.—The Solstice Mining & Milling Co., with offices in Bisbee, has made a contract for machinery totaling more than \$10,000 and will begin active development work as soon as it can be erected. The company has been financed for \$50,000 by a Chicago bonding company.

BISBEE.—Notices have been posted by the Copper Queen Branch of the Phelps Dodge Corporation in Bisbee to the effect that a number of men will be laid off at the Sacramento Hill property on November 1. The reasons given are that materials for carrying on construction of the new mill are delayed and that the company has not sold any copper since March 1. The management further stated that \$13,000,000 had been expended since the first of the year in construction and operation and it was necessary to stop all unnecessary expenditure. The Solstice Mining & Milling Co. was recently financed by a Chicago bonding company for \$50,000, thus making possible the order just placed for \$10,000 worth of machinery to carry out sinking and other exploration work.

During the past week the major portion of the business section of the town of Lowell was destroyed by fire, which

also threatened the mine office of the Calumet & Arizona Mining Co., at the Junction shaft. Estimates have placed the total loss at over \$750,000. In the early part of this year an electric mechanical shoveler was tried out in the Junction mine of the Calumet & Arizona Mining Co. This machine was used only in headings in the driving of drifts. During the first trials there was naturally considerable loss of time due to numerous mechanical defects which had to be overcome. In the late spring another type of shovel, operated by compressed air, was experimented with; in general it was found much easier to keep in continuous operation than the electric shoveler. A large type of shovel has been used at Inspiration for several years, the work being entirely in large headings. Recently, these have been replaced by smaller shovels operating with compressed air. The smaller shovel is much more convenient, is more easily moved, and has not the large amount of complicated machinery to be taken care of, which forms a part of the other machine.

AJO.—From a concession recently given the New Cornelia Copper Co. to build a railroad from the international line to the Gulf of California, thorough north-western Sonora and north-eastern Lower California, Bahia de Roca (Rocky Bay) appears to have been determined upon as the tide-water terminus for the proposed Ajo-Gulf of California railroad. This indicates that a bridge will be built across the mouth of the Colorado river, well within Mexican territory, for the bay is an indentation of the western gulf shore. It is now proposed also to build a direct automobile road from Ajo to one of the two eastern ports named, and a survey of the route now is in progress. There is assurance that the Mexican end of the road will be built through the famous Altar mining district by the Mexican government.

MAYER.—The Arizona Binghamton, one of the largest mines in the Mayer district, has closed down temporarily owing to the present condition of the copper market.

JEROME.—Steam-shovel operations west of the former office building of the United Verde mine have opened up an orebody 75 to 100 ft. wide in the black schist. It is said that the ore runs more than 4% copper and that some of the ore contains as much as 15% copper. This body of ore was exposed in an old drift and has been known for some time but has never been developed or worked. Present exposures do not show how large the orebody is. Two of the three shifts employed in sinking the Jerome-Superior shaft have been laid off. The reason for the reduction in force has not been given.

MIAMI.—J. Klinfelter, G. J. Berthold, P. Sullivan, B. Flood, and S. Sutton, claim owners in Lost Gulch, have filed suit for \$500,000 against the Inspiration-Miami Copper Co., Inspiration-Miami Extension Copper Co., and the Globe Copper Co. The plaintiffs claim that the defendants, under the name of the Inspiration-Miami Copper Co., agreed to pay \$400,000 to them for a group of claims, which sum has never been paid. They further allege that the personnel of the three companies is the same and that the three companies were used to transfer stock and properties back and forth in such a manner as to defraud the defendants.

COLORADO

VANADIUM FOUND NEAR TELLURIDE.

ASPEN.—A power-line has been extended to the Hope tunnel and a full force is again working in the heading. Supplies have been laid in for continuous winter operation. The Turley tunnel in the old Ashcroft district, 15 miles south of Aspen, projected to cut the rich Tam O'Shanter vein, has been financed by Aspen operators. The tunnel will intersect the Tam O'Shanter approximately 2500 ft. below the surface. Six other veins, one the Michigan, and an immense fault, believed to be the centre of rich mineral deposits, is in due line with the survey course of the tunnel. The Aspen Silver Lead Mines has started construction on a power-line from Meredith to its property on Porphyry mountain.

BRACKENRIDGE.—Increased freight-rates have resulted in curtailment of mill and mine operations by the Wellington Mines Co. The increase, amounting to \$2.50 to \$3.75 per ton, would cause loss, and one of the biggest zinc-producing mines in the State and the largest employer of labor in Summit county is expected to cease production soon. The pumps, however, will be kept in operation and a small force kept at work on development. Efforts of the management to secure a fair rate on concentrate and ore shipments to date have failed. Bulkeley Wells and associates have ceased operations on the Iron Mask and pumps have been pulled, development in the lower workings failing to warrant continuation. The upper level has been leased. Remaining equipment for the Laurium mill of the Blue Flag company has been shipped and as every preparation has been made for immediate installation, it is expected the plant will be in operation early in November.

CRIPPLE CREEK.—October production of the Modoc Consolidated Mines Co. will approximate 2700 tons of ore with an average value of \$30 per ton. This increased output, which brings the company into the front rank of district producers, is the direct result of the discovery about 7 weeks ago at the 1300-ft. level. Here the south-eastern extension of the Orpha May-Ruby-Last Dollar-Modoc system has been proved and an orebody averaging between 25 and 27 ft. wide, in places 42 ft. between walls, has been opened up for 120 ft. in length. Stopping has started and ore shipped to date has averaged \$30 per ton. More powerful machinery is under construction for the

No. 2 or Last Dollar shaft of the company and with the new plant in commission and miners available 3000 tons monthly can be mined and shipped. The No. 2 shaft of the Portland Gold Mining Co., on Battle mountain, has attained a depth of 2450 ft. and a station is now being cut at an elevation of 7794 ft., the deepest working in the entire district. Ore mined at the level above continues high-grade. Settlement on a carload shipment from the Hardwood, Ironclad hill, property of the United Gold Mines Co. made last week was at the rate of \$155 per ton. The lessees shipped another 40-ton lot this week estimated at between 8 and 10 oz. gold per ton.

Drilling has commenced on a second diamond-drill hole at a site selected on Galena hill, about three-quarters of a mile north-east of Cameron. The new hole will be drilled at an angle of 45°. The Bolivia and other phonolite dikes have been opened in shallow workings in this section and it is expected mineralization will be found in the drill-core that will warrant development. The first test drilled to 1386 ft. showed mineralization below the granite capping.

LEADVILLE.—Not only has the authorized increase in freight-rates been cancelled through the efforts of the Leadville Chamber of Commerce, but in addition the American Smelting & Refining Co. has been induced to cancel its recently announced increase in treatment charges on certain low-grade ores and to reduce charges on all ores with less than \$10 net smelter return that contain less than 35% excess insoluble, and similar ores with more than 35% insoluble if the content does not exceed 2½% sulphur. The announced reduction materially benefits the smaller operator and lessee. Sinking is in progress under contract at the Blain shaft and production is maintained at 25 tons daily of 25% zinc ore. A more powerful electric hoist has been put in place and with the shaft at the 350-ft. level, increased production is expected.

A promising zinc orebody has been opened up by lessees on the Lilian in Iowa gulch. Ore-bins are being constructed. Lessees on the A. V. within the city limits have several hundred tons of a good-grade manganese-ore ready for shipment and awaiting cars.

TELLURIDE.—The Valley View Leasing & Mining Co. is mining good ore at Matterhorn and the mill is running steadily. A three-car shipment of concentrate was consigned to the Durango smelter last week. Vanadium-bearing rock has been found in the white cliffs less than half a mile from the city limits. A test made by the Colorado Vanadium Co. showed high vanadium content and the company's engineer is on the ground making locations. Many claims have been staked.

MICHIGAN

LABOR SITUATION IMPROVING.

CALUMET.—Geological research work which the Calumet & Hecla began a year ago is progressing, but because of the volume of work necessary it may be a year or two before any definite conclusions are drawn. An effort

will be made to determine, if possible, the origin of native copper and the processes by which it was deposited. If this result can be attained it will greatly simplify the work of finding new copper deposits. Samples are being taken from various veins of the Keweenaw formation and the results of the analyses will be correlated in the hope of evolving dependable rules for use in exploratory work. The survey is of interest to every mine in the district, for if it is successful the information will be available to all.

An improvement in the labor situation, reported by Mohawk, is one of the most encouraging developments recorded in the Lake region in many weeks. While not large, it is sufficient to indicate that the labor problem is disappearing. Mohawk has a market for its copper and if it can get men enough it will proceed with the development of the fissure which appeared most promising on the 22nd and 23rd levels of No. 4 shaft. Because the entire force is needed for regular operations, it has been necessary to temporarily suspend the opening up of this vein. The fissure was first encountered about 1400 ft. south of No. 4, on the 22nd level, and openings in the foot and hanging wall revealed it to be well charged with heavy copper. The same showing was noted on the 23rd, where the fissure was about 100 ft. closer to the shaft, and in addition to heavy copper, 'mass' was found. Contiguous to this fissure the main vein has widened out to the abnormal depth of 40 ft. in some places, and this so-called 'wide spot' has been opened down to the 24th Mohawk's No. 1 shaft, temporarily idle, which will come into its own again with the restoration of normal conditions. Much ground remains to be mined by this shaft, which has approximately 900 ft. more to go before it reaches the property limits.

Seneca has completed the concreting of its shaft and by the end of the week will have removed the forms, permitting the completion of the cross-cut to the vein on the 5th level. Drifting then will be pushed and the level opened north and south. On the 4th level the south drift has reached the boundary, while the north drift is 725 ft. long. The north drift on the 3rd level is 790 ft. long and, like the 4th, is breasted in ground that compares favorably with any opened heretofore. Seneca is making irregular shipments to the Baltic mill instead of letting the 'rock' accumulate on the ground. For the present the management will content itself with development work instead of production.

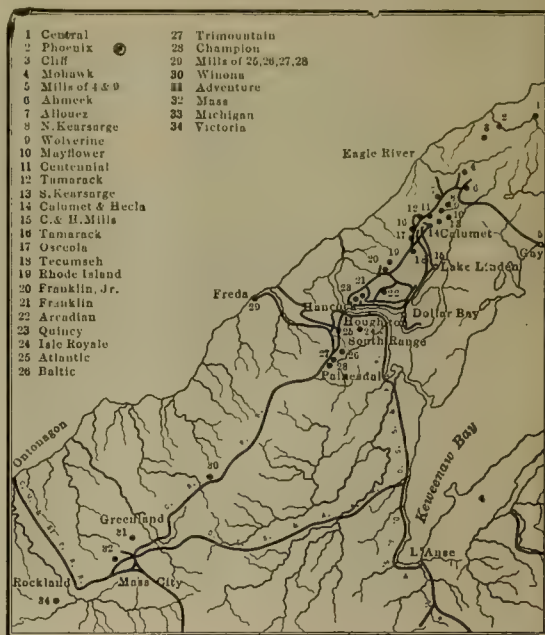

Figures revealed in the annual report of the Houghton county inspector of mines are somewhat startling, for they show that during the past year the combined forces of all of the mines in the county numbered only 6083. This compares with 7865 in 1919 and 16,423 in 1917. The fact that a marked improvement has been noted during the past four weeks, however, is reassuring. The Calumet group alone reports a net gain of 60 men per week. The county figures do not include Ahmeek, Mohawk, Allouez, or the mines south of Champion. A curtailment of operations in the automotive centres accounts for the betterment in the labor situation here.

Mayflower's south drift still continues in good vein matter, though the mineralization is not as heavy as a week ago. It is the plan to continue the explorations on the 1700-ft. level so that portion of the mine will be thoroughly opened before attempting any work of an extensive nature on the 1400-ft. level. It was in the latter that the Mayflower lode was originally uncovered.

NEVADA

THE NIVLOC NORTHERN MINES CO. ORGANIZED.

COMO.—Gurney Gordon, general manager of the Como, in giving his reasons for closing the mines, says in a statement to stockholders: "We feel that it is not profitable to operate a producing mine under present conditions. The miners are not satisfied with the present wage-scale and we cannot pay more because of the general low

MICHIGAN COPPER DISTRICT

efficiency of labor. We have hoped for a reduction in the price of supplies for the last two years, also for improved labor conditions, but they have grown worse every month. We feel that it is not good policy to deplete our ore-reserves further under these conditions, for, using as a basis the purchasing power of money five years ago, we can only figure the value of our gold at \$8 per ounce and silver at 40c. per ounce at the present time." The Como was paying the Virginia City wage-scale. The statement says the increased price of powder, lumber, and lime since January 1, 1920, has added \$1500 monthly to the operating costs. There is \$2,500,000 worth of \$10 to \$12 ore blocked out in the mine, according to the statement. This is being treated in a 100-ton mill.

TULE CANYON.—The Silver Hill company, operating the Ingalls under option, has stopped all work that was being done by contractors. This was the result of a tele-

gram from W. J. Loring, ordering the work stopped until "after election", according to one of the contractors. The mill is not working on ore, but tailing is being retreated with cyanide.

VIRGINIA CITY.—Miners employed in the North End mines have been notified by Alex Wise, superintendent, that the \$5 wage-scale paid before the strike early in September will become effective again on January 1. Since the strike the scale has been \$6. This will be done, according to the manager, so that other companies, unable to operate under the advanced scale, can resume. He says that in view of general declining prices the \$5 scale "will work a hardship on no one and will create at least four or five times the present opportunity for employment".

WEST DIVIDE.—A two-drill compressor is in use at the West Divide, L. L. Patrick, manager, an ore-bin has been built and is being filled, and new buildings have been completed. A drift is being driven north on the main-tunnel level in a vein parallel to that in the shaft and short cross-cuts are being driven as the drift is advanced. The north drift on the 65-ft., or shaft-level, also is being continued. The ore-shoot, after having been only a few inches wide for a distance of 12 ft. at this depth, is widening. Assays of as high as \$1900 in silver and lead have been secured recently from two and three-inch widths. Then men are employed.

SILVER PICK.—The Nivloc Northern Mines Co. has been organized to further develop 15 claims formerly owned by the Nivloc Mines Co., eight miles south-west of here. Officials of the company say a 100-ton mill is to be built to treat \$10.50 ore. A. G. Cummings, formerly in charge of the Nivloc, is the organizer and manager of the new company, and associated with him are Fred Remick, formerly superintendent for the Montezuma Silver, Henry C. Schmidt, John M. Cotton, and John R. Cunningham. The ore, in quartz veins with limestone walls, is said to be free-milling. The main work is done through a 420-ft. shaft, from the bottom of which a cross-cut penetrates four veins of a total width of more than 100 ft. Practically all of the work is on the bottom level. About 300 ft. of cross-cuts and an equal amount of drifting have been done on that level and one raise has been driven a short distance. More than \$300,000 has been spent in development.

GOLDFIELD.—George Meuli, a Lone Star lessee, has completed in a Gibson mill a trial run of 25 tons of \$200 ore. Practically all of the free gold was saved by amalgamation, but the loss in telluride is estimated to have been \$25 per ton. The tailing may be treated with cyanide at the mill or it may be shipped.

MONTENZUMA.—The Washington Montezuma, after being idle since 1914, has resumed work. An 18-hp. hoist, 32-ft. head-frame, and five buildings have been erected. Montezuma is a silver-lead district, but the Washington ore contains gold only. Assays as follows have been obtained in a 200-ft. shaft: 4 ft., \$11; 10 ft., \$22.40; 10 ft., \$12.20. A drift has been driven 140 ft. from the bottom of the shaft and this is now being ex-

tended. Later it is planned to sink the shaft deeper. The company owns two claims. The vein, quartz with limestone walls, is 45 ft. wide at the bottom of the shaft. The officers, all Chicago men, are R. H. Kiehne, president; John J. Sullivan, vice-president and manager; Gustav Schulz, treasurer; John M. Zamecnek, secretary. Sullivan is a police sergeant making his first venture into mining as a manager and, without assistance, he has done well so far.

PIOCHE.—No action has been taken as yet by the officials of the Salt Lake Route toward reducing freight-rates on ore shipments, although promises and assurances have been made to the larger producers. During the week ending October 16, the Prince Consolidated shipped 1510 tons; Virginia-Louise, 515; Bristol Silver Mines, 150; Black Metals, 100; Combined Metals, 55; Currency Lease, 40; Zero Lease, 40; making a total of 2410 tons.

UTAH

'SPECIAL CONTRACTS' DECLARED DISCRIMINATORY.

SALT LAKE CITY.—The U. S. Bureau of Mines has allotted \$27,000 for co-operative experimental work at various institutions in Utah, and has allotted \$7500 to the Idaho Bureau of Mines and Geology. These sums must be matched by State contributions. On October 19, the Public Utilities Commission of Utah handed down a decision in the so-called 'special contract' cases, involving the Utah Power & Light Co.'s schedules for power service in this State. These special contracts allowed 56 of the largest customers a rate for current considerably lower than that paid by other customers receiving similar service. The investigation was begun on September 27, 1919, when an order was issued by the Commission, stating that the special contracts were "discriminatory and preferential". The initial hearing was begun on December 8. The metal-mining companies involved include the United States Smelting Co., American Smelting & Refining Co., Silver King Consolidated Mining Co., Utah Copper Co., and other prominent coal and metal-mining companies. These companies are placed, for the time being, on standard schedules. During 1919, the total earnings of the Power company were \$4,431,846, of which amount the special contract holders contributed \$1,781,434. Under the decision, the special contract holders will be called upon to pay approximately a million dollars additional per annum for their current. The Utah Copper Co. alone, in some years, has consumed more than one-half of the Power company's output. The contract rate per kilowatt hour is 4.8 mills, and the standard schedule for such service is 8.2 mills. The Power company contended that it was furnishing power to the Utah Copper at about 40% of the actual cost of such power. The special-contract holders contended that a contract, lawful when made, should, under the constitution of both the State and nation, be held inviolable from interference by legal authority. On October 21, attorneys for several of the mining companies filed petitions asking for a rehearing of the case.

GOLD HILL.—Exploration work at the Success mine, about four miles from here, is meeting with conditions which promise well for the future of the property as a producer, according to S. M. Fleming, who is in charge of the property. On the 200-ft. level, for a distance of 350 ft. along the strike of the vein, an average of two feet of silver-lead ore, valued at \$30 per ton, has been opened up. This ore, it is stated, extends to the surface. A carload of carbonate ore, mined on the surface, is ready for shipment. The vein, which traverses the granite-limestone in a north-south direction, has been developed by an inclined shaft sunk on the dip of the fissure. The mine has been equipped with modern machinery by the owners of the property, George Peters & Sons of New York City.

BINGHAM.—On October 20, Federal Judge Tillman D. Johnson handed down three decisions in the six cases

construction of a new power-line to Big Cottonwood canyon, which should ensure continuous power throughout the winter. A new and shorter road to the property has been finished, which will expedite the handling of material to and from the mine.

PARK CITY.—A body of iron sulphide, in which bunches of good copper-silver ore occur, has been found in a drift from the Spiro tunnel in the Silver King Consolidated mine, about seven feet from the tunnel. Some of the ore assayed 9% copper and 13 oz. silver. Samples of gray copper from one of the other fissures encountered by the Spiro tunnel gave assays of 128 oz. silver and \$32 gold per ton. A feature of the iron-sulphide development is the fact that all of the approaches to the Parsons stope in the upper workings of the mine, from which approximately \$1,500,000 worth of ore was taken, passed through heavy iron sulphides. Present operations are being

OFFICE OF THE PHELPS DODGE CORPORATION AT TYRONE, NEW MEXICO

pending between the Utah-Apex Mining Co. and the Utah Consolidated Mining Co., whereby five of the suits were decided in favor of the Utah-Apex and one in favor of the Utah Consolidated. R. H. Channing, Jr., president of the Utah Consolidated, states that his company will at once move to take the cases decided against it to the United States Circuit Court of Appeals.

ALTA.—An assessment of 1c. per share has been levied on the stock of the Howell Mining Co. The levy is delinquent November 16. Recently the company was granted permission by the State Securities Commission to sell a block of treasury stock at 10c. per share. The Alta Tunnel & Transportation Co. has awarded a contract for 200 ft. of work in the east drift from the Alta tunnel, according to F. V. Bodfish, manager. The drift is following one of the Prince of Wales fissures through a broad zone of the brecciation of the type in which have been found the orebodies of the Emma and other Alta mines. The drift is now 600 ft. below the bottom of the Prince of Wales shaft. The company has completed the

financed by the sale of short-term convertible 7% notes. The notes are convertible into stock on a basis of \$2 per share. The company's last annual report showed that receipts from the sale of these notes during 1919 totaled \$128,200. Shipments of ore from six mines in this district for the week ending October 16 totaled 1832 tons, of which the Silver King Coalition shipped 519; Judge M. & S., 401; Daly West, 353; Ontario, 376; Keystone, 83; Naildriver, 60. The Judge smelter shipped 40 tons of premium spelter.

Operations at the electrolytic smelter of the Judge Mining & Smelting Co. were suspended on October 22, as a result of the decision of the Public Utilities Commission to allow the Utah Power & Light Co. to increase power-rates. The Judge company is one of the holders of 'special contracts' for power service. The low price of spelter and increased mining and refining costs make operations of the smelter inadvisable and unprofitable, according to G. W. Lambourne, general manager.

The new milling-plant of the Keystone Mining Co. is

about 80% complete. A crushing-plant of 100 tons daily capacity will be erected. Officials of the company believe the new plant will be ready for operation soon after the first of the year. By an agreement with the Silver King Coalition, the Keystone company has been using the Hanauer tunnel for the purpose of developing its property, and several ore showings have been opened up during the past year. By using this tunnel, the Keystone company was able to do development work at a depth of 800 ft. below the deepest of the old workings.

EUREKA.—Preparations are being made to resume work at the property of the Diamond Queen Mining Co., about 3½ miles south of Silver City. Buildings have been erected and the necessary equipment purchased. A connection was recently made with the Silver City water system to supply the necessary water. The shaft will be deepened; a hoisting equipment good for a depth of 1000 ft. is now being installed. An assessment was recently levied on the outstanding stock of the company, the proceeds of which will be used for the development.

Shipments of ore from this district for the week ending October 16 totaled 123 cars, of which the Chief Consolidated shipped 37; Tintic Standard, 27; Mammoth, 14; Dragon, 13; Iron Blossom, 7; Grand Central, 6; Iron King, 4; Centennial-Eureka, 3; Eagle & Blue Bell, 3; Swansea, 2; Victoria, 2; Gemini, 2; Bullion Beck, 2; Colorado, 1.

A contract has been let by the East Crown Point Mining Co. for sinking a main working-shaft, according to Charles Zabriskie, manager. The shaft is being sunk for assessment work. George Adams, who is in charge of the development at the property of the Dagmar-Northwest Mining Co., reports that the sinking of the shaft will be resumed. It is now 190 ft. deep and it is the intention to continue sinking until the 500-ft. level is reached, when drifting will be commenced.

High-grade streaks and bunches of ore are appearing in the face of the drift on the lowest level of the Eureka-Lilly mine, which is 1600 ft. below the surface, according to Grant Snyder, manager. Work is progressing in a satisfactory manner on the foundations for the machinery at the South Standard property, according to E. J. Radatz, president. The shaft at this property will be one of the largest in this district, having four compartments; one compartment being used solely for ventilation purposes. A power-line has been erected between Tintic Standard and the South Standard properties. While most of the work at the old Centennial-Eureka mine is being handled by lessees, the company is also doing considerable prospecting and shipping some ore. The company owns a few claims adjoining the Mammoth mine, and a drift is being driven for the purpose of prospecting this ground.

BRITISH COLUMBIA

HIGH-GRADE ORE BELOW PRESENT WORKINGS IN THE
DOLLY VARDEN.

USK.—Considerable activity in prospecting continues to be shown in this district, although the season is rapidly

drawing to a close, snow already having appeared on the hills. A promising 10-ft. belt of ore is being developed at the Silver Horde group, at the head of Chiminess creek. The orebody contains numerous stringers of gray copper, varying from the thickness of a sheet of paper to a foot in width. Recent assays of culled ore have run 15 to 20% copper and 200 to 300 oz. silver per ton. The Kleanza Mining Co. has been finding some rich gold ore on its No. 5 claim; assays have given as much as 4 oz. in gold and 15% copper.

On Bornite mountain, three miles from Usk, the Hazel group is being developed with promise of a successful outcome. The ore is chalcopyrite and bornite, with a small quantity of gray copper. Specimens have been assayed with returns of 28 oz. silver, 24% copper, and 0.10 oz. gold. Tunnel operations are to be started on a vein about five feet wide of mixed high-grade and milling-ore. There is a large mineralized dike in this section which has been cut by Emma creek and by the action of the water the ore was exposed. From the Peerless claims of the same locality was taken a specimen that weighed over 100 lb. and is estimated to contain 50% copper. Epidote and hornblende form the matrix of the vein from which this was taken. It has been stripped for over 100 ft. and several deep cuts made, the result being the uncovering of 26 in. of high-class ore, the remainder for a width of 7 ft. being milling-ore. There is one hundred tons on the dump for shipping and plans are being made for the resumption of operations next season on a large scale. There is a force of fifteen men at work on the Kitselas Mountain Copper Co.'s property, also near Usk. North and south drifts respectively are being driven on No. 1 and No. 2A veins and a foundation of concrete is being laid under the mill and so extended as to provide for an addition when one is required. The concentrates coming from the chalcocite and bornite ore are high-grade, giving returns of 48% copper, 40 oz. silver, and 2.20 oz. gold per ton.

TRAIL.—Despite the fact that little ore is reaching the smelter from the Sandon and other Slocan camps, the total received each day has been mounting gradually, and recently has averaged well over 1000 tons. During the first 14 days of October, 16,033 tons was received, the Consolidated M. & S. Co. mines contributing 13,669 tons. The other shippers were: Bell, Beaverdell, 41 tons; Bluebell, Riondel, 157; Emerald, Salmo, 33; Florence, Princess Creek, 133; Granby, Grand Forks, 107; Iron Mask, Kamloops, 53; Josie, Rossland, 627; Monarch, Field, 42; North Star, Kimberley, 343; Ottawa, Slocan City, 30; Paradise, Lake Windermere, 47; Rambler, Cariboo, 43; Ruth, Cedar Creek, 118; Silver Bell, Zwicky, 44; Spokane-Trinklet, Ainsworth, 39; San Poil, Republic, Washington, 228; Skyline, Cedar Creek, 53; Venus, Yukon, 54; and Wellington, Beaverdell, 80 tons.

HAZELTON.—James Cronin, manager of the Babine Bonanza, has announced that the cross-cut has reached its objective and has penetrated a 12-ft. orebody, but that until proper machinery to facilitate mining has been erected no further work will be done on the vein.

From now on the whole force will be occupied in getting ready for and erecting machinery. J. S. Kelley, who is developing a 3-ft. vein at the Judge group, Babine range, has been taking out ore recently that assayed up to 100 oz. in silver. It also contains some copper.

PRINCE RUPERT.—High-grade ore, similar in character to that obtained in the present workings, has been penetrated 500 ft. below the present workings by a diamond-drill at the Dolly Varden mine. This has greatly encouraged the owners of the property, as it fairly well establishes persistence to that depth, at any rate. No assay of the ore found has been announced, and even had the ore been assayed the result would have been of little value, as the high-grade found at the Dolly Varden is decidedly spotty. About 20 tons of it is being shipped each month to Tacoma, and brings average return of about 1000 oz. per ton, but the assays of individual pieces of this class of ore will give anything from 100 to 5000 oz. The main thing is the finding of this class of ore in depth, as many were of the opinion that it was entirely a near-surface product. Some high-grade gold ore has been discovered up the George river, which runs into the Portland Canal 17 miles below Stewart. Some of the big paper interests have been examining the Ecstall iron-pyrite property, with a view to utilizing the mineral for the manufacture of sulphuric acid. The Granby company had this property under option for some time, and explored it thoroughly with a diamond-drill. H. S. Munro, manager for the Granby, stated recently that the property contains an immense body of iron pyrite, and undoubtedly some day would be worked for that mineral, but that the copper content was appreciably less than that of the Hidden Creek ore.

STEWART.—The Algonquin Development Co. has decided to postpone further development of the George group, situated on the south side of Bear river, Portland Canal mining division, until next season. Considerable progress has been made in opening up the property of the Indian Mines Ltd., situated on the west side of Cascade creek, between the Salmon River glacier and Cascade creek. The claims are at an elevation of 2400 ft. and fourteen miles from tidewater. Development consists of three open-cuts on the croppings and two tunnels. The former expose a vein from 12 to 20 ft. wide, which can be followed on the surface for about 2000 feet.

ALICE ARM.—For some weeks there has been a force of about 200 men employed at the Dolly Varden mine. The railway from the mine to the Alice Arm townsite will have to be closed down during the winter. It is understood that some 65 men will be kept on the payroll for development in the mine during the closed season.

SLOCAN.—The lost vein of the Evening Star mine is reported to have been found from the old tunnel, and there are indications that the old property will be in the shipping class again before long.

GRAND FORKS.—A. M. Johnson, who is interested in the Molly Gibson mine at Paulson, states that there are good prospects of the property being a regular shipper, seven feet of high-class ore having been uncovered in the

old shaft. The intention is to sink to the tunnel, which has been driven into the mountain a distance of 200 feet.

MARYSVILLE.—The Canadian Consolidated Mining & Smelting Co. is about to commence the construction of a concentrating mill on the old site of the Marysville smelter. Preliminary work is in hand.

MANITOBA

OREBODY OF THE FLIN FLON ESTIMATED TO CONTAIN
24,000,000 TONS.

FLIN FLON.—Excellent progress is being made in testing the Flin Flon copper property in north-western Manitoba, which is under option to Col. W. B. Thompson of

HEAD-FRAME OF THE MANDALAY MINE, JUNGO, NEVADA

New York and associates. The originally planned expenditure of \$200,000 for exploration will be considerably exceeded, as operations now in progress will call for an outlay of about \$350,000 as transportation difficulties render working costs very high. It has been ascertained that the orebody formerly estimated to contain 20,000,000 tons will probably run to about 24,000,000 tons. An examination was recently made by Henry Krumm and Andrew J. McNab, chief engineers for Col. Thompson and associates. No. 1 shaft was down 200 ft., the ore was cross-cut disclosing 300 ft. of ore and No. 2 shaft had reached the same depth exposing 185 ft. of ore. From No. 1 shaft drifting was extended 500 ft. south. It was planned to sink each shaft an additional 100 ft. and undertake other development to prove the orebody to a

depth of 300 ft. The option expires March 31, but the Thompson interests must announce their decision by January 1 to the Manitoba government, to allow the latter time to consider the building of the Pas railroad.

ONTARIO

PRESENT WAGE-SCALE WILL NOT BE CHANGED.

COBALT.—The wage-scale at the mines in the Cobalt district is the subject of discussion among the Workmen's Councils. With silver below 80c. per ounce, a flat wage has been paid, with a bonus of 25c. daily for each ten points which silver may advance above that price. Early in the year, on \$1.37 silver, the bonus amounted to \$1.50 daily. In May, last, the companies announced their intention to pay a bonus based on silver at \$1.20, regardless of the lower price. This has meant a daily bonus of \$1.50, although silver has declined to under 90c., which entitles the workers to a bonus of 25c. only. This bonus of \$1.50 was assured until November 1, and with that date approaching, the workers are endeavoring to obtain from the operators the assurance that this rate will be continued.

Official advice from the Mining Corporation of Canada shows that this company will produce as much silver during 1920 as in the previous year. The achievement is remarkable because the output promises to exceed the amount of silver estimated to be in the reserves at the beginning of the year. The company is opening up the Buffalo mine, which was purchased early in the year, but has not yet commenced to draw ore from this source. It is also unofficially reported that negotiations have been opened with a view to purchasing the Hudson Bay mines, or at least that part of the property lying west of the Townsite mine.

Bullion shipments during the third week of October from the Nipissing amounted to 152 bars containing 200,411 oz. of silver, while in the corresponding period the Mining Corporation sent out 98 bars containing 99,950 oz. This is about 50% above the average.

On October 16 high-grade ore was found at a depth of 100 ft. in the Ruby Silver mines. Including the narrow high-grade streak and the silver-impregnated wall-rock, the silver-bearing material has a width of three feet. Business men of Cobalt have a lease on the property.

The Anvil Lake Silver mines, in the Maple Mountain section of the Elk Lake district, is being re-opened. Meantime, British interests, represented by J. B. Tyrell, are negotiating for the control of the White Reserve mine which lies within a mile of Anvil Lake.

Dr. W. G. Miller, Provincial Geologist for Ontario, and Thomas W. Gibson, Deputy Minister of Mines, are making an official tour of inspection through the mining districts of Northern Ontario.

The Casey-Cobalt, which has produced about 2,500,000 oz. of silver, has gone into voluntary liquidation.

PORCUPINE.—The diamond-drilling on the Porcupine-Miracle south of Night Hawk lake has been completed comprising about 1200 ft. which has disclosed a wide zone of mineralization. Further diamond-drilling is being

considered. A two-ton shipment of ore from the Clifton-Porcupine when milled gave a return of \$66 per ton.

KIRKLAND LAKE.—In the Bidgood a drift on the 300-ft. level has cut what is believed to be the vein on which the shaft was sunk at a distance from the shaft of 86 ft. The drift is being continued to tap a vein, which showed up on the surface. A new mineralized body has been encountered east of the shaft.

BOSTON CREEK.—Work has been resumed at the Mondeau which was closed down recently on account of unsatisfactory labor conditions. The Kennedy-Boston is planning to resume underground operations shortly. The force is at present engaged in surface work.

LIGHTNING RIVER.—Active mining operations will be carried on throughout the winter by the Lightning River Mining Co. A force of men has been sent in with a full supply of provisions and material.

BOURKE'S STATION.—The four Wickstead-Oleson claims at Lion Lake have been taken over on option by a syndicate representing Toronto and American capital.

MATACHEWAN.—The Matatchewan Gold Mines has completed an extensive diamond-drilling campaign comprising 15,000 ft. of drilling, the results of which are stated to be satisfactory. The greatest depth reached was 600 ft. In addition two shafts have been put down by hand-steel from the first of which 1000 ft. of lateral work has been accomplished on the 200-ft. level. Further development has been deferred until a supply of electric power can be obtained from Indian Chutes on the Montreal river.

TORONTO.—The Imperial Oil Co. of this city has received confirmation of the report that oil had been found on its claims at Fort Norman on the Mackenzie river near the Arctic circle. The first statement was to the effect that the flow of oil was from 1000 to 1500 barrels per day, but a message from the company's geological party, which has returned to Edmonton, while corroborating the news of the strike gives no details as to the flow.

Fort Norman occupies a commanding position on the east bank of the Mackenzie river in the southern angle formed by the entrance of the Great Bear river. It is situated 65° north and 126° west. For long it has been a point of interest on account of the immense beds of lignite which have been burning for the last 130 years, the fires being first noted by Alexander Mackenzie in 1789.

Fort Norman is 900 miles from the nearest calling-point of a river boat, and 1200 miles from the nearest railroad. The only means of access at the present time is down the northern rivers, and these will float boats of only four or five feet draught, and several rapids necessitate the unloading and reloading of cargoes. This precludes bringing oil up the river in quantity until adequate transportation conditions are provided. Added to these disadvantages, the severe cold reduces the period of navigation to three or four months in the year.

The Imperial Oil Co. has staked nine miles along one side of the river and eight miles along the other. This includes the islands in the river. The oil is of excellent quality, running about 40° Baumé.

CALIFORNIA

Butte County.—Power restrictions which compelled the Feather River dredge No. 3 of the Natomas Co. to close down, have been lifted and orders have been received in Oroville that the big gold boat shall begin operations again. The removal of the power restrictions on gold dredging followed the recent rains.

Nevada County.—The Idaho-Maryland 15-stamp mill is nearly ready but the lower workings of the mine are still filled with water. The hoist for the winze at the Alcalde mine has arrived and will be put in place immediately.

Plumas County.—Work is being pushed on the property of the Reinmuller Copper Mining Co. in the Lights Canyon district. The company holds about 50 claims by locations, bond, and option joining the Engels mine on the north. A tunnel is being driven to cut the ore about 275 ft. below the surface. John Reinmuller is president. John F. Cowan is one of the directors. The main working and drainage tunnel at the Walker mine has been driven over 4800 ft. gaining a depth of 1000 ft. on the dip of the orebody. A raise from this tunnel is being completed to No. 4 level, an approximate distance of 450 ft. The raise is said to have exposed rich ore. It is understood that the capacity of the flotation mill will be materially enlarged early in the coming year.

Sierra County.—The Kate Hardy mine is showing some

good prospects. The drift from the 100-ft. level has opened up a pay-shoot with ore that will run very high. Decision has been reached to begin work this fall on a 300-ft. tunnel to tap the channel in the Bella Union-Poor Boy mine. It is planned to continue the work all winter. The property lies on what is known as the Port Wine ridge and has been extensively prospected by drilling-machines during the past summer. L. A. Thatcher, of San Francisco, who has purchased the machinery at the Gold Point mine, is shipping the machinery to his holdings in other parts of the State.

Yuba County.—The lifting of the power-restrictions in effect since early summer, has permitted the resumption of gold-dredge operations on the Yuba river. Two or three of the eight boats operated by the Yuba Consolidated Gold-fields Co. were shut-down, but these boats have been again placed in commission. The other boats, which were working but part time each day, are now operating continuously.

IDAHO

Burke.—The Imperial Mining Co. will make a 700-ft. raise from its lower tunnel to the winze sunk from the upper workings. It will be started 3000 ft. from the portal of the lower tunnel. Homer Brown, secretary, says arrangements are being made to secure a small sawmill with which to cut the lagging and stulls for the raise. About 85,000 ft. of timber will be required. Several streaks of quartz have been found in the face of the lower tunnel of the Washington Mining Co.'s property, according to reports. Assays give a return of several ounces of silver per ton. In the upper tunnel of the property a stringer of galena ore more than a foot in width has been found.

Wallace.—The Callahan Zinc-Lead Co. shipped 4,230,000 lb. of zinc concentrate in September. In the same period it shipped 2,180,000 lb. of lead concentrate and 21,800 oz. of silver. At the time of the dividend disbursement, September 30 last, it was announced that development was proceeding on the Nipsic and Interstate veins. The Hope Mining & Milling Co. has obtained title from the State of Idaho to its property on the east side of Pend Oreille lake, 1½ miles from Hope, where the State recently sold a total of 3240 acres. This property was formerly known as the Morning Star group, for a long time supposed to be on Government land and was so located. Directors of the company say that, now that title has been secured, work will be resumed in a short time and a 1500-ft. tunnel driven to cross-cut six or seven veins. The new tunnel will be 600 ft. below the present main tunnel. In the upper tunnel 14 in. of high-grade ore was uncovered. A 45-ton car of silver-lead concentrate was shipped recently by the Big Creek Mining Co. in the Coeur d'Alene. The new mill of the company is running full time and treating 75 tons per day. Important in the plans of development of the company is the raise which will soon be commenced in the lower tunnel to reach the next tunnel above which is 550 ft. higher. From this raise levels will be opened for the extraction of ore for the mill. The Columbia section of the American Institute of Mining and Metallurgical Engineers will hold its annual meeting in Kellogg and Wallace, October 29 and 30, according to announcement issued by L. K. Armstrong of Spokane, chairman of the section. One session will be held at Kellogg and

the Bunker Hill works and smelter will be inspected. Another session will take place at Wallace and various mines and mills adjacent to Wallace will be visited.

NEW MEXICO

Lordsburg.—It is reported that the diamond-drill work in progress at the 85 mine, recently purchased by the Calumet & Arizona Mining Co., is resulting favorably.

Mount Franklin.—Alfred Roos and associates are reported to have purchased what is said to be, from surface indications, one of the largest fluorspar deposits in the country, situated in the extreme northern part of the Franklin Mountain range, just north of the line between New Mexico and Texas, and about 25 miles north of El Paso. The two vein-systems are said to be more than a mile long, and the quality is believed to be excellent, containing no other impurity than silica.

WASHINGTON

Spokane.—The Bead Lake Mining Co., seven miles from Newport, in Pend Oreille county, owned largely by Spokane capital, is building a 100-ton concentrator to be completed by the first of the year. Two separate properties are owned by the company. One is copper and the other silver-lead. Both are developed to the stage where they are capable of steady production. The galena lode has been developed on four levels to a depth of 500 ft., showing a vein from 8 to 14 ft. wide, most of the vein being a high-grade milling-ore with much first-class ore. Copper holdings of the company adjoin the silver-lead property and have been developed to a depth of 750 ft. The vein is two to four feet wide, the ore being chalcopryrite. From the bottom of the shaft the vein has been followed 700 ft., the ore being low-grade most of the distance.

MEXICO

Coahuila.—Approximately 6000 coal miners in the State of Coahuila are reported to be out on strike, and several men have been killed in encounters between workers and soldiers protecting the coal mines at Agujita.

Sonora.—The construction of a railroad from Agua Prieta on the international border over the Sierra Madre mountains to Casas Grandes on the east side of the mountain range, is reported to have been authorized by the Mexican government. The route of the road will be over the Pulpito Pass on the Sierra Madre mountains and north-west to Agua Prieta. An extension will connect, it is said, with the Southern Pacific of Mexico, south of Nogales. The total length of the proposed road will be nearly 200 miles. After a ten day trip in Sonora, T. B. Johnson and J. E. Meyers of El Paso, are reported to have discovered and denounced the Klondyke placer. Fifty pertenencias or 125 acres covering about two and a half miles up and down the gulch, including dam-site for storage of water for hydraulic purposes, have been denounced. The property is located about 90 miles south of Naco, and about five miles from the Monte Cristo mine, owned by a syndicate of prominent business men. The Monte Cristo mine is reported to be in operation and extracting high-grade silver ore from the mines as well as working over the old dumps. This mine has a record of having yielded approximately \$1,000,000, and 10 carloads of concentrate shipped to the El Paso smelter yielded \$150,000.

Mose Sevey, an American citizen, superintendent of the Cananea-Duluth mine of the Cananea Consolidated Copper Co., was fatally injured on October 20, due to a gunshot wound inflicted by a Mexican employee.

Hidalgo.—The Compania de Real del Monte y Pachuca, Mexican subsidiary of the U. S. Smelting & Refining Co., and situated at Pachuca, has recently purchased the Arevalo properties about six miles from Pachuca for \$1,250,000.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. W. Bradley is at Kellogg.

R. A. F. Penrose, Jr., passed through San Francisco last week.

W. C. Minsch is with the Minas del Tajo, at Rosario, Mexico.

Philip Wiseman is in New York, on his way home to Los Angeles.

H. R. Bischoff is with the Crown Reserve Mining Co., at Cobalt, Ontario.

Gilmour E. Brown is visiting the Chino Copper Co., at Hurley, New Mexico.

F. F. Friant, recently at Dos Cabezas, Arizona, is now at Port Orford, Oregon.

M. G. F. Sohnlein is in Holland. He expects to return to Chile early next year.

H. C. Goodrich, chief engineer for the Utah Copper Co., was in San Francisco recently.

P. K. Lucke has gone to Europe, from Mexico, and will return at the end of December.

Harvey S. Mudd left New York on October 22, on his return from London to Los Angeles.

Robert D. Longyear, of the E. J. Longyear Co., of Minneapolis, was in San Francisco this week.

David White, Chief Geologist, U. S. Geological Survey, is visiting the branch office in San Francisco.

S. F. Hunt, lately superintendent for the Tybo Lead Co., at Lucin, Utah, has moved to Tecoma, Nevada.

Charles P. Richardson, manager of the Slim Jim mine, at Sawyer's Bar, California, is in San Francisco.

Thomas M. Bains, Jr., is now at the Missouri School of Mines, at Rolla, having left Mariposa, California.

Fred B. Ely is making a geologic survey for oil and gas in Coahuila, Nuevo Leon, and Tamaulipas, in Mexico.

John D. Hoffmann is consulting engineer to the Mawchi Mines Ltd. and Yuanmi Gold Mines Ltd., with headquarters in London.

George E. Collins, of Denver, has been in New York. He is chairman of the Flotation Conference to be held at Denver as a part of the meeting of the American Mining Congress.

Garret Mott, president of the Castle Dome Mining Co., and chairman of the executive committee of the Superior & Boston Copper Co., together with John Kasser, is at Globe, Arizona.

Walter Harvey Weed announces that he has severed all connection with Harris & Co., of 25 Broad street, New York. His addresses are 29 Broadway, New York, and Tuckahoe, New York.

J. G. Flynn has resigned his position with the Miami Copper Mining Co., at Miami, Arizona, to accept a position as mine superintendent with the El Oro Mining & Railroad Co., at El Oro, Mexico.

G. F. Loughlin, Chief of the Division of Mineral Resources, U. S. Geological Survey, and Charles G. Yale, in charge of the San Francisco office of the Survey, will be at Salt Lake City early in November.

Gerald R. Simpson, recently superintendent for the Standard Minerals Co., at Kingman, Arizona, has opened an office in the Haas building, at Los Angeles, as manufacturer of his invention, a pneumatic flotation-cell.

F. H. Curry, formerly with the Inspiration Consolidated Copper Co., sailed on October 22 from New York on his way to the Belgian Congo, where he is to be mill superintendent for the Union Minière du Haut Katanga.

THE METAL MARKET

METAL PRICES

San Francisco, October 26

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	8.50
Copper, electrolytic, cents per pound.....	17.50
Lead, pig, cents per pound.....	7.50—8.50
Platinum, pure, per ounce.....	\$95
Platinum, 10% Iridium, per ounce.....	\$135

Zinc-dust, cents per pound.....	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

October 25.—Copper is inactive and nominal. Lead is quiet and weaker. Zinc is dull and easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

JAPANESE COPPER SPECULATION

"Exportation of American copper to Japan has ceased," says "The Boston News Bureau". "Since January 1, 1920, there has been shipped to the Orient 80,000,000 lb. of copper, of which a large proportion, it is believed among domestic producers, has been re-sold and shipped to Europe in competition with American agencies abroad.

"During the three years ended June 30 last, there had been exported to Japan 146,349,518 lb. of copper, of which 139,980,773 went out in the last period, indicating the extraordinary movement which was getting under way during the first half of 1920.

"The movement had apparently been completed last June, with shipments in that month of 4,417,980 lb. July saw the exportation of but 940 lb. to that country, while in August not a single pound was sent over.

"That the movement was almost entirely speculative producers admit, while further confirmation appears in the actual shipments, which have been as follows (pounds):

Year to June 30, 1920.....	139,980,773
1919	6,287,620
1918	81,125
Three years	146,349,518
July 1920	940
August 1920	none

"A decade ago there was a somewhat similar movement of copper to the Far East, although at that time shipments were sent to China, where, it was said at the time, heavy minting was to be undertaken. It was later developed, however, that the buying of many millions of pounds of copper for Chinese account covered an extraordinary speculative operation."

SILVER

Samuel Montagu & Co. says: "It has been rumored that there have been sales of bar silver from India to China. The last named country is now in the remarkable position of sustaining, like a modern Atlas, the silver market of the world—less the 45,000,000 oz. per year absorbable under the Pittman Act. It is important to notice that, if the report be true, the markets have had two sources of supply besides production, namely, demonetized silver from the Continent, and an overflow from India, which might almost be described as demonetization in that quarter. There is no doubt that it was the probability of the export of silver rupees becoming feasible as a result of the position of exchange that impelled the Bazaar price downward to about 108 rupees the 100 tolas—that is to say, 2 3/4 rupees per 100 tolas below the Indian intrinsic value of full-weight rupees.

"We remarked long since that the extremely large remittances of silver to China the last year or so, were not only owing to the replacement of the silver shipments made during the War from that quarter to India for coinage, but also to the ill odor into which paper money had fallen as a consequence of the Russian debacle. This distrust of notes still continues in the interior of Asia, and it may be taken for granted that China is for a while in a position to import and retain, or to consign into the interior, more silver than in the past—perhaps even 50,000,000 or 60,000,000 oz. per annum. This accounts for the ease with which China has continued to take the metal. It is stated that the imports of silver into China have amounted to nearly 52,000,000 oz. between the beginning of January and the end of August this year."

MONEY AND EXCHANGE

Foreign quotations on October 26 are as follows:

Sterling, dollars:	Cable	3.47 3/4
	Demand	3.48 1/2
Francs, cents:	Cable	6.40
	Demand	6.41
Lire, cents:	Cable	3.80
	Demand	3.80
Marks, cents	1.49

Eastern Metal Market

New York, October 20.

There is no life in any of the markets and the tendency in most of them is downward.

Copper values have touched new low levels on this movement on free offerings. Sales have been very light.

The tin market continues quiet and featureless. Prices have again declined.

The lead market is the most stable of all, but demand is very light.

The buying of zinc is of small proportions with the tendency easy.

Antimony is lower.

IRON AND STEEL

The movement toward lower prices for pig-iron and the products of independent steel mills is more rapid and there are more shut-downs and curtailments of production, says 'The Iron Age'. Signs now point to a decline in both pig-iron and steel-ingot output in October, though an increase was indicated as the month came in.

The most significant development of the week is a break in coke, which apparently marks the end of the extreme prices that have ruled for months. With a decline of \$2 per ton in the week and both blast-furnace and foundry operations on a diminishing scale, considerable contract coke is being released meanwhile, buyers once more have something to say in that market. The efforts of the Ford Motor Co. for a revision of its contracts on cold-finished steel bars have met with fair success.

The belief that activity will succeed the present hesitation early in the new year is prompting the policy in some cases of adjusting operations for the time being to the limited demand, without pressing for new business. Meanwhile concessions are largely confined to the smaller mills.

Two large consumers of tin plate on the Pacific Coast, one at Seattle and the other at Vancouver, have been covered for their first half of 1921 needs by the American Sheet & Tin Plate Co. at that company's maintained \$7 basis.

COPPER

The copper market has continued to decline and new low levels have been reached on this movement. There is no question but that the outside producer, so called, and the dealers have cut values decidedly. In some cases these reductions are being met and sales have been made at the lower values by some large producers. But the amount of buying is light and not a fair test of the market. Nevertheless there has been some business. The market for both Lake and electrolytic copper may be quoted at 16 to 16.50c., New York, for early delivery. Sales have been made at 16.25 and 16.37½c. There has been some business done in the last week for export at prices considerably above the foregoing values. Consumption continues good and production is decreasing. Sentiment is not pessimistic in all quarters and the worst is believed to have passed.

TIN

Quietness continues to characterize this market and there are no features. It is reported that a moderate business was done during the last week by dealers and consumers on future-shipment metal, but as a whole the market is devoid of life or animation. It is partly disheartened. There are reports also of financial difficulties in the Far East and in Holland which have resulted in failures on a large scale in some places and may end in others. The effect of the British coal strike is being watched. As a result there have been bear raids on the London market which have depressed prices some £20 per ton. This has had its sympathetic effect

here and values have declined. Spot Straits tin was quoted yesterday at 38.25c., New York, though it was 37.75c. on Monday. In London spot Straits fell to £240 10s. on Monday, but recovered to £243 15s. yesterday. There was a recovery also yesterday of £2 to £3 in spot and future standard tin to £241 15s. and £247 10s., respectively. Arrivals thus far this month have been 1565 tons with 5075 tons afloat.

LEAD

This market has been the least affected of all recently. Demand is exceedingly light. The only feature was another reduction in the price of the leading interest on Monday of ½c. per pound to 7c., St. Louis, and 7.25c., New York, which was a readjustment to the outside market. We quote the market 7c., St. Louis, or 7.25c., New York, with imported metal at about the same as the New York market or 7.25c., seaboard, duty paid. The domestic market is very close to being lower than, or as low as, it is possible to import lead.

ZINC

This market is quiet, fairly steady, and devoid of features. Prices have eased slightly and prime Western for early delivery is quoted at 7.25c., St. Louis, with the imported metal, re-shipped from England, available at 7.50c., New York, or seaboard. The effect of the British strike may be to reduce the quantity from this source. Producers are cutting production and declining to sell except where necessary, confident of the future market's strength.

ANTIMONY

The market is quiet and easier with wholesale lots for early delivery quoted at 6.50 to 6.75c., New York, duty paid.

ALUMINUM

There has been a revision of prices by the leading producers. Virgin metal, 98 to 99%, is quoted now at 32.90c. f.o.b. producer's plant. The outside market is quoted at 28.50 to 29.50c., New York.

ORES

Tungsten: Off-grade Chinese ore has sold in moderate sized lots at \$4.50 per unit. Other grades are in poor demand and nominally unchanged. Bolivian ore is quoted at \$5 to \$5.50 and 60% scheelite at \$6 per unit. Ferro-tungsten is unchanged.

Molybdenum: The market continues quiet with prices nominal at 75c. per pound of MoS₂ in regular concentrates.

Manganese: Demand is light. One consumer has offered 42c. per unit for several thousand tons but was unsuccessful. The last sale was at 53c.

Manganese-Iron Alloys: Re-sale ferro-manganese has sold in small lots on a basis of \$155, seaboard. The regular quotation is \$170, seaboard. Demand is very light. The spiegel-eisen market is inactive but strong at \$80 to \$82.50, furnace, for the low and high-grade, respectively.

AMERICAN METAL TO SELL CERRO DE PASCO OUTPUT

The Cerro de Pasco Copper Co., at the expiration of its present contract with the American Smelting & Refining Co. the last of this year, will switch the refining and sale of its product to the American Metal Co. The production under capacity operation will run above 100,000,000 lb. of copper per annum. This constitutes the largest and most important change among the copper-selling agencies in the past few years, one of the most recent having been the withdrawal of the Copper Range Co. from the United Metals Selling Co. group and the subsequent establishment of its own sales department.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

ALLIS-CHALMERS BALL-GRANULATORS

The ball-granulator, as developed by the Allis-Chalmers Manufacturing Co., was originally designed to crush 2 or 3-in. ore down to a fineness of 10 to 80-mesh. Actual experience has shown it to be equally efficient as a fine grinder when reducing 8 to 20-mesh feed to anywhere from 100 to 200-mesh. The company claims that after careful study of

type of mill, when crushing coarse material the ore receives the force of the impact of the balls and all this energy is utilized in crushing. When reducing 3-in. feed, the large feed acts as a cushion for the balls, but with fine feed, say one-half inch or less, the pulp does not offer sufficient resistance to give a cushioning effect, with the result that the balls strike on the shell-lining, causing excessive wear of both lining and balls. By maintaining the pulp-level at a point sufficiently high to interpose a bed of pulp to partly cushion the impact of the balls, the maximum crushing effect with the minimum wear of steel is obtained.

In no other ball-mill except the Allis-Chalmers ball-granulator is there any means for controlling the pulp-level except by regulating the feed of ore and water. It is impossible to maintain such regulation at a fixed rate and ratio, hence the pulp-level cannot be regulated accurately by this means. The idea has been to design a mill in which the pulp-level can be positively controlled to suit the varying conditions arising in practice and to maintain a high crushing efficiency and a low ball and lining-consumption. The pulp-level in the Allis-Chalmers ball-granulator may be varied from the periphery to a point approximately half way between the trunnion and the periphery. This variation is obtained by the patented G-H diaphragm. This device consists of a diaphragm with radial ribs cast on the back and with round openings between the ribs opposite the screen or grating. On the inner face of this diaphragm is mounted a grating or screen made up of high-varbon tool-steel bars, disposed radially and tapered to obviate blinding. The spaces between the grates are covered with liners held in place by through-bolts; with the apertures in the diaphragm left open the mill will discharge to within 3 or 4 in. of the periphery, but by closing the outer ring of openings with wooden plugs the discharge is raised accordingly and by this means

Variable-Discharge Diaphragm

the principles of ball-mill grinding and the troubles encountered with the earlier designs constructed for this work, it has succeeded in producing a mill that eliminates the difficulties heretofore encountered, and added several special features, which are hereinafter described more fully.

Recent experimental work on the crushing of coarse material in ball-mills shows that the most efficient crushing effect is obtained by direct impact of the falling balls. While it is true that a large amount of grinding is done by attrition, or by the rubbing of the balls upon each other, it is believed the crushing of coarse material is effected mainly by impact and that attrition acts principally on fine material. For practical purposes, we may assume that the pulp in a ball or tube-mill remains level and that this level is fixed by the height of discharge and is not affected laterally by centrifugal force at the speeds obtaining in ball-mill practice. In the open trunnion-discharge type of mill, half full of pulp, a great deal of useful energy is wasted by the balls falling through a thick pulp, thereby reducing the force of their impact. On the other hand, in a peripheral-discharge

the pulp-level in the mill can be accurately regulated to suit the material crushed. Thus, without any change whatever in construction the mill can be adapted to almost any ration of crushing and also for varying tonnages. The radial ribs act as elevators lifting the pulp and discharging it at the trunnion level. Access to the wooden plugs may be had through the hand-holes on the outside of the mill. The grates can be replaced without removing the mill from the foundation or dismantling it.

The capacity of the Allis-Chalmers ball-granulator with variable-discharge diaphragm is from 30 to 40% greater than the trunnion-discharge type mill with an increased power-consumption of about 20% when discharging at the periphery. As the height of discharge is raised the capacity and power decrease proportionately until the maximum height of discharge is reached (a point about half way between the trunnion and periphery), when the increase in capacity is 15 to 20% and the power 10% over the open trunnion discharge.

The ball-granulators are designed for using hard iron or

steel balls as a crushing medium. A mill loaded with balls has a capacity about 2½ times greater than when loaded with pebbles. Balls increase the capacity in direct proportion to the increase in weight. The weight of balls and height of fall determine the maximum size of feed that can be crushed. This explains why ball-mills loaded with 3 and 4-in. balls take a coarser feed than tube-mills loaded with pebbles of the same size. The capacity and power increase directly with the ball load until it reaches a level slightly below the axis. Further loading does not increase the capacity, whereas the power increases proportionately. Although in tube-mill practice the pebble load is carried up to or in some cases above the axis of the mill, it is not necessary or ad-

Allis-Chalmers Ball-Granulator Crushing Quartz Ore

visible to carry the ball load up to the axis in an Allis-Chalmers granulator, in fact, experience would show that on some ores the greater efficiency is obtained by carrying the ball load as much as 8 or 10 in. below the axis.

BOILING-POINTS OF WATER UNDER REDUCED PRESSURES

The following table is found useful by the engineers of the Oliver Continuous Filter Co. and we give it for the benefit of those engaged in similar lines of industry.

Vacuum		Boiling-point		Altitude	
Inches	Millimetres	Deg. F.	Deg. C.	Feet	Metres

The Holt Manufacturing Co., Inc., of Peoria, Ill., is issuing a small bulletin with illustrations of its 'caterpillar' tractors pulling road-making machinery and engaged in the actual work of road-making. With the illustrations is given a detailed statement of the cost of operation compared with animal haulage on the same job.

COMMERCIAL PARAGRAPHS

The Mine & Smelter Supply Co. announces the appointment of Harry J. Gundlach as sales manager of its Denver branch.

The Henry E. Wood Ore Testing Co. has removed its assay office and chemical laboratory to 1750 Arapahoe street, Denver, Colorado. Hereafter this branch of the business will be known as The Henry E. Wood Assaying Co.

The Cement-Gun Co., Inc., of Allentown, Pa., has recently issued a small booklet showing the results of tests made on reinforced gunite floor-slabs together with working and safe-load tables, established by the tests, for this type of construction. The data therefore are both new and useful.

Dwight P. Robinson & Co., Inc., engineers and constructors, consolidated with Westinghouse, Church, Kerr & Co., has appointed Carl C. Thomas as its Western representative, with offices in the Electric Equipment building, 1240 South Hope street, Los Angeles.

The Walworth Manufacturing Co., Boston, Mass., has recently issued Export Catalogue No. 35 for pipe-fittings and similar material. This catalogue is printed in English, Spanish, French, and Portuguese with conversion tables and index. Everyone with foreign experience realizes the difficulty in translating technical terms and extra attention has been given to making this as correct as possible. The catalogue is intended for use only in those countries using British standard thread.

R. D. Nuttall Co., manufacturers of gears, pinions, and flexible couplings, has equipped new and permanent quarters at 429 Title & Trust building, Philadelphia, Pa., to handle direct, all business other than electric-railway and mine-haulage supplies. This office will be a direct Nuttall office and will be in charge of R. F. Fiske.

The Nordberg Manufacturing Co., at Milwaukee, Wisconsin, has just completed an extension of its main machine shop and bays. The new addition, which is 200 by 180 ft., will facilitate the erection of large engines and hoists, such as the 2000-hp. Diesel oil-engine and several large hoists now on order. One of the latter, known as the Mitsue hoist in Japan, will be the largest hoist ever exported.

Dwight P. Robinson & Co., Inc., (with which Westinghouse, Church, Kerr & Co., Inc., has recently consolidated), engineers and constructors of New York, has established a new branch office in Youngstown, Ohio, in the Home Savings & Loan building, in charge of C. I. Crippen. The company recently moved its Cleveland office from the Leader News building to the Citizens building, and H. P. Clawson, who was for several years a member of the Chicago staff, has been transferred to Cleveland to take charge of this office. The company now maintains branch offices in Pittsburgh, Youngstown, Cleveland, Chicago, Dallas, and Los Angeles, and Sao Paulo, Brazil.

The Westinghouse Electric & Manufacturing Co. is distributing Motor Application Circular No. 7132, entitled 'Electrification of Excavating Shovels', which describes and illustrates the various uses to which electric shovels may be put, such as railway work, coal-mining, and drag-line excavating. The method of electrifying is discussed, together with an outline of the choice of equipment. Advantages of electric shovels are fully considered and results of recent tests are given, that show the cost per cubic yard of material removed by means of these shovels. Tables are produced which show the approximate energy-consumption of electric shovels and drag-line excavators.

NOTES	647
THE RISING TIDE OF COLOR	648
The book by Lothrop Stoddard and its bearing upon the Japanese problem in California. This immigration only a part of a larger movement, whereby the colored races, especially in Asia, are pressing outward into the countries of the white peoples and establishing colonies, as the white people have done among the dark races. The migration of the poorer racial stocks of Europe and their effect on the people of the United States.	
STORES IN MINING COMMUNITIES	649
The establishment of a company store or employees commissary by the Nevada Consolidated Copper Co., and the reasons therefor. Why the Judge Mining & Smelting Co. went into the merchandising business for the benefit of its employees.	
DISCUSSION	
THE HUMAN FACTOR IN MINE MANAGEMENT	
By Sam A. Lewisohn	651
The manager of mining enterprises usually has a technical education and is not trained in handling human beings, hence does not realize its importance. Mining engineer liable to become dehumanized unless he pays special attention to his 'human contacts'. Labor-unions usually pass through two phases. Second stage is reached when unions endeavor to safeguard interest of their employer as well as their own.	
WAR MINERALS RELIEF	
By W. J. Loring	653
An appreciation of the work of the War Minerals Relief Commission. Personal experience of a claimant.	
IRON AND STEEL IN INDIA	
By E. F. O. Murray	654
Iron and steel industry of India assuming larger proportions. New deposits of ore. Miscellaneous mineral production.	

ARTICLES

METAL PRICES AND MINING IN MEXICO	
By H. G. Nichols	655
The effect of changing metal prices on the grade of ore minable at a profit with reference to a special case.	
THE MINE AND MILL OF THE BELMONT SHAWMUT MINING COMPANY—II, THE MILL	
By Arthur B. Parsons	659
Description of the stamp-mill. Flow-sheet. Gravity concentration. Re-grinding in tube-mill. Flotation unit. Fuel-oil, wood-creosote, and sodium sulphide. Treatment of concentrate by cyanidation. Edwards roasters. A mixture of raw and roasted concentrate better than either alone.	
A JUDGE ON EXPERTS	665
The judge is 'peeved at' expert testimony but seems to think the experts do the best they can.	
GEOLOGISTS AS EXPERT WITNESSES	
By F. L. Ransome	666
Difference between the scientific and legal attitude of mind. Apparently believes that expert witnesses should be appointed by the court as amici curiae.	
INTERVIEWS WITH GOVERNORS OF ZACATECAS AND DURANGO	
By Our Representative, Alberto Terrones Benitez. The Governors of Zacatecas and Durango tell their opinions of and plans for the mining industry in their respective States.	667

That You May Be Served Promptly

LINDE Oxygen must reach Linde customers *on time*, Neither tie-ups nor storms, floods nor fires shall interrupt Linde Service and to that end every means of transportation is called into use.

When the regular channels of commerce are closed, when man or nature keep the wheels from turning—Linde finds a way. By trolley, motor, mule-train or sled through ice-jammed waters, or over burning sands—Linde must live up to its promises—must *deliver* wherever it is humanly possible.

Because of this super-service, oxygen users throughout America depend upon Linde delivery with as much confidence as they depend upon the uniform purity of Linde Oxygen.

That is why Linde must produce more oxygen than any other maker in the world.

THE LARGEST PRODUCERS OF OXYGEN IN THE WORLD

T. A. RICKARD, Editor

RECOGNITION of the new Mexican government seems assured at an early date, and we are glad of it. We should aim to maintain as friendly relations with our southern neighbor as with our northern. Señor Obregon has given every evidence of a desire to establish an *entente cordiale*.

SILVER production of the world will fall short of the pre-war rate by fully 29,000,000 ounces, according to estimates submitted at the International Financial Congress at Brussels. The production for 1920 is placed at 195,000,000 ounces, as against 223,900,000 ounces in 1913. This ought to strengthen the silver market.

OUR London contemporary, 'The Financial Times', talks about the boom in Mexican shares in a most cheerful way. The favorable turn in political affairs has synchronized with the cutting of a rich orebody in the Esperanza mine at El Oro and generally favorable developments in British-owned mines in other districts, notably Pachuca. Esperanza shares rose within a month from 13 shillings to 50 shillings, so that somebody made some money. The shares of the old Exploration Company have risen considerably, and, in general, there is a sentiment highly favorable to Mexican mining. Several new ventures are said to be on the eve of flotation.

WE sympathize with the Judge whose colloquy with Mr. William E. Colby we quote on another page. He started to make some criticisms on expert testimony in general and found that he had hurt the feelings of several gentlemen whom he knew to be honorable men; so he returned to the subject and disclaimed any personal attack. The colloquy is interesting and that is why we quote it. So is the contribution on the same subject from Mr. F. L. Ransome, who writes as the editor of 'Economic Geology', and as one wholly detached from the delicate situation created by the adaptation of scientific testimony to mining litigation.

AT the forthcoming convention of the American Mining Congress, at Denver, on November 15 and following days, there will be public conferences on a number of timely topics. The use of the flotation process and the terms of licensing will be the subject of one meeting, to which representatives of the Minerals Separation com-

pany have accepted an invitation. A report on the Federal Trade Commission's investigation of the Minerals Separation company's methods will be presented. A National Gold Conference is to discuss the gold problem in relation to mining, and Representative McFadden will be present, to explain the advantages of the Bill he has introduced for the levy of an excise tax on the gold used in manufacture. On the same occasion Mr. H. N. Lawrie, statistician for the Mining Congress, will review the legislative campaign for the relief of the gold-mining industry.

NEXT Thursday we celebrate the second Anniversary of the Armistice, yet we are still technically at war with Germany. Four days later the League of Nations assembles at its new headquarters in Geneva, whereas we have not yet made up our minds whether to join or stay out. Meanwhile the League has succeeded in arranging the dispute between Poland and Lithuania, and has intervened successfully between Sweden and Finland, which otherwise might have gone to war over the Aland islands. Furthermore, the moral pressure of the League has caused the Russians and the Poles to cease hostilities. All this is of good augury. When are we going to give a hand in the good work?

FROM a recent official bulletin, issued in the City of Mexico, we note that out of 1261 mercantile establishments in the State of Sonora, four were American company mine-stores, 430 belonged to Mexican, American, German, and other owners, and 827 were Chinese. In capital, \$755,000 represented mining-company stores, \$1,080,000 was American and European, \$978,540 was Mexican, and \$2,186,935 was Chinese. Of the 827 Chinese stores, 740 had a capital of less than \$5000 and only 11 had a capital of more than \$10,000. The increase in Chinese is given: from 850 in 1900, to 4000 in 1910, and 12,500 in 1919. As a class, the bulletin says, they are healthy, honest, and industrious; however, they are addicted to drugs, have low standards, and work as single men, so that they compete on favorable terms with other nationals having families.

LITIGATION over the Minerals Separation patents is making slow progress. The Nevada Consolidated Copper Company and the Magma Copper Company are the two latest defendants. They have answered the

plaintiff's bill of complaint with a general denial of the charges of infringement. The Nevada company in its reply alleges that the Minerals Separation people at various times asserted that their process "could not be adapted to ores such as those of the defendants". It also avers that "things alleged to be patented had been abandoned to the public", and that the Minerals Separation people are not the original inventors of the process, citing the names of patentees of earlier processes. The Magma company follows its general denial by questioning the plaintiff's statement of a readiness to grant licenses; it avers that Minerals Separation insists on restrictive terms and conditions of license. Meanwhile the suit against the Miami Copper Company is dragging along, the Master's hearing on alleged profits not having been finished as yet.

WE take keen pleasure in publishing a contribution from Mr. Sam A. Lewisohn, of Adolph Lewisohn & Sons, a firm identified with large and successful copper enterprises. His subject is the human factor in mine management, concerning which he is able to write convincingly not only by reason of his intimate connection with mining but also on account of a liberal and humane spirit, without which any discussion of the subject would be sterile. Indeed, we shall not progress far in the improvement of industrial relations until men of character and authority show themselves willing to come forward and discuss delicate points frankly and fairly, as Mr. Lewisohn does. We shall be glad if others will continue the discussion.

AS truth is stranger than fiction, so actual mine reports are weirder than any that one could concoct. Among recent examples of the delirious trimmings of geology we quote from a report on the Carmen Creek district, in Idaho. The author, who calls himself a "consulting, mining and metallurgical engineer", says: "The formation consists of Alkonkian Shist, which through the Igneous Magma forming the Dyke as a Bysmalith breaking through the older formation. In its action of rising the meshing and grinding force, produced by the force below, ground the Shist to a Clayey Calcarrious Argillareous mess to the West and North, and to the East and South to a Shistose Shale or Shist. The Magma itself carrying some mineralization with it, which, and being encast through the period of crystalization, the most of the minerals staying below in molten state was carried in the state of vapor aided by the action of water as an Aquallarious Igneous fume through the crevices of the slowly cooling Magma." It is evident that the typist contributed to this appalling result, but not sufficiently to spoil the style of the original. Indeed it is a "clayey calcarrious argillareous mess", and it seems astounding that such a document could be given forth seriously. The author estimates the property to contain 2,920,909 tons—note the meticulous precision—of ore that he calls "probable ore in the developed area, blocked out", leaving his client to choose between the three terms, 'prob-

able', 'developed', and 'blocked out'. This supposed ore contains \$5.50 in gold and silver, and the cost of mining it "under economical conditions should not exceed 20 cents per ton, leaving a big margin over the cost of metallurgical treatment". But the question arises, what process under the sun could treat successfully such a "clayey, calcarrious argillareous mess"? It sounds a bit sticky.

THE BUREAU OF MINES has announced the program of investigations to be undertaken at the newly created Mississippi Valley experiment station, together with several appointments of members of the staff. Apparently headquarters for the Station will be at St. Louis, where Mr. J. J. Rutledge is to be acting-superintendent, whereas the actual research on ore-dressing and milling, and on the electro-thermic metallurgy of zinc, will be done at Rolla, in conjunction with the Missouri School of Mines. Mr. John Goss will be in charge of milling and Professor Charles H. Fulton, director of the School of Mines, will supervise the work on smelting, in the capacity of consulting metallurgist to the Bureau. The investigation of the best methods of sharpening, tempering, and using drill-steel is to be undertaken in collaboration with the North-Central station of the Bureau, which is at Minneapolis. The question suggests itself, why is the administering to be done in one place and the actual work in another? If Rolla is the most desirable place for the station, should not the offices also be there? We wonder too, why it is necessary to select for investigation a problem that has already been assigned to another station. This must mean either duplication or dissipation of energy, neither of which is conducive to efficiency. There must be some valid reason for these things that does not appear on the surface. It is to be hoped that the taint of politics has not touched the Bureau.

The Rising Tide of Color

This is the title of a remarkable book by Mr. Lothrop Stoddard. We shall discuss its main thesis apropos of the Japanese question in California, to which we turned in our issue of October 16, and to which Mr. C. A. Grabill contributed in our issue of October 30. The immigration of Japanese into California may be considered as a part of the tide of color that menaces white civilization. According to Mr. Stoddard the white race at a time of weakness, consequent upon the European war and the ensuing disintegration, is menaced by "a definite movement half-conscious and half-instinctive against the white world-supremacy", which has been established by four centuries of domination. Before that, in the fifteenth century, the tide of colored invasion nearly submerged Europe; the Turks captured Constantinople, the Tartars swept over the plains of Russia; the Moors occupied half of Spain; the brown men dominated the shores of the Mediterranean. Thereupon the people of Northern Europe took to the sea and colonized distant lands with their virile stock; the dark invaders were driven back

into Asia and Africa; the white race laid the foundations for a new supremacy, typified by the United States. Groups of white people migrated to the countries of the dark peoples and established outposts, which within the last four hundred years have won dominion over a large part of the world inhabited by the dark peoples. Australia and Africa are entirely subject to white control; nearly all of North America; a small part of South America; and a large part of Asia. Of the dark races, those of Asia are asserting themselves; the Chinese, the Japanese, and the Hindoos have progressed in intelligence, in material wealth, and in population. The pressure of population has set loose the forces of racial rivalry; the Asiatic hordes look hungrily toward foreign areas of colonization and begin to reverse the tide of migration. The movement is unorganized; it is largely instinctive and individual; it is not prompted by official suggestion as yet; it is an ethnic phenomenon that in time may develop into a conscious racial demand for self-determinative freedom from "the white man's burden" and for possession of the productive regions of the earth. Mr. Stoddard makes no effort to excite prejudice against the colored race, but he emphasizes the fact that the white and the colored cannot live side by side without injury to the former; in the ensuing competition the white race becomes sterile, while the dark one breeds rapidly. As he says: "A generation ago relatively few persons realized that low-standard men would drive out high-standard men as inevitably as bad money drives out good, no matter what the results to society and the future of mankind. These are but two instances of that shallow cocksure nineteenth-century optimism, based upon ignorance and destined to be so simply and tragically disillusioned." Mr. Stoddard's remedy, in brief, is to leave the whole of Asia to the Asiatics, while barring them from America, Canada, and Australia. A reviewer in 'The Spectator' demurs to this proposal, fearing that the result will be to turn Asia into "a seething pot of anarchy", but the question may well be asked, if the races of Asia are to continue to multiply, whither is the surplus to go if not to the Asiatic hinterland? In conclusion, Mr. Stoddard extends the problem of racial incompatibility to the lesser breeds of the white race; he says: "Even within the white world, migrations of lower human types like those which have worked such havoc in the United States must be rigorously curtailed. Such migrations upset standards, sterilize better stocks, increase low types, and compromise national futures more than war, revolutions, or native deteriorations." Here he enlarges the problem bewilderingly. Undoubtedly the incursion of the Japanese is part of a much larger problem, namely, the submergence of the racial stock of the American people by alien breeds, not only from Asia but also from Europe. Immigration from south-eastern Europe has replaced that which formerly came from the races akin to the founders of the United States. It is true, the European assimilates better with our stock, but as the immigration comes now chiefly from countries not in a condition of healthy

vitality and from peoples in a backward stage of development, these late additions to our native stock have a low genetic value. The Japanese that come to California—we do not speak of the higher classes—are superior to the lower type of European and they are incompatible genetically with our people, so that there is less miscegenation. The birth-rate among the descendants of those who founded this republic is declining to a deplorable degree, whereas the incoming foreigner is prolific. We must face the fact that the American type developed before the Civil War is being degraded by an influx of uncongenial aliens; the original stock is being overwhelmed by immigration from both directions, from across the Atlantic as well as from over the Pacific. The destiny of the United States is overshadowed by the possibility of a tragic catastrophe. The Anglo-Saxon and Anglo-Celtic elements, which it is the fashion now to term Nordic, but which to us are typified by the Virginians and the New Englanders, the original settlers of America, men of the idealistic and energetic Elizabethan type, are being swamped by the incoming tide of alien and lower breeds, bringing customs, traditions, and standards of living discordant with the aims and ideals of this republic.

Stores in Mining Communities

Small events may be interesting on account of their significance. For instance, within the last few weeks the two general mercantile stores at Ruth, Nevada, have been closed, permanently, after a number of years of flourishing business that proved highly profitable to their proprietors. The underground and open-pit mines of the Nevada Consolidated Copper company are at Ruth and until a few months ago the employees of the company purchased a large proportion of their food-supplies as well as some shoes, clothing, hardware, and drygoods, from these two local merchants, the next nearest market being at Ely, ten miles down the canyon. Neither the mining company nor any of its officials were even indirectly interested in either of these stores; nor was there any desire on the part of the company to influence its employees to patronize any one store or market in preference to another. The miners were absolutely free to buy what they needed where they could get the best price, and, in the face of what competition existed, the two stores at Ruth were prosperous. The employees, however, felt the increasing pressure of rising prices, and accordingly the company last summer started an 'Employees Commissary' to distribute at cost some of the staple provisions. While the plan was an experiment at first it was supported so enthusiastically by the employees that the variety of the stock was increased to include practically every kind of food, in addition to sundry other household supplies, shoes, and some kinds of clothing. There are now two stock-rooms, one at Ruth for the benefit of the community about the mines, and the other at McGill, where the mill and smelter employees are supplied. The saving to the average man with a family amounts to fully 25% of what he formerly paid. The employees them-

selves have a voice in the administration of the commissary in that they select the directors, subject to the approval of Mr. C. B. Lakenan, the general manager for the company. The business is financed by the company but is conducted with the sole aim of supplying the employees with the things that they require at cost; they get the advantage of efficient buying in large quantities, and in large markets, by competent men. A novel feature, and one that reduces the cost to the consumer, is the method of distribution at the mine. On the first and fifteenth of each month an 'order-blank and price-list' effective for the ensuing two weeks is printed, and several thousand copies are distributed at the various time-offices. The prices for each article are figured from the net cost of the material, plus freight, and the actual expense of distribution. It has been found advisable to establish and publish a definite price beforehand rather than to oblige the housewife to do her ordering and then wait several weeks to know exactly how much she has spent. The practical result is virtually the same and it is much more comforting to the purchaser, who is usually a woman. Completed orders must be turned in at the time-office or at the commissary on or before the 8th or 23rd of the month and deliveries are made on the 10th and 25th. We venture to suggest that the need for anticipating one's requirements for a fortnight in advance has stimulated efficiency in household economy; perhaps it has helped to develop more than one household-engineer; it is the beginning of a budget system, such as Uncle Sam needs. There are no losses due to bad accounts because payment is made through the time-office by deduction from the employee's pay-check. Coupon-books are sold to enable small purchases at any time between delivery-days, but the customer must carry home her own merchandise, so only a small proportion of the business is done in this way. The commissary has been in operation about four months, but its success is attested by the promptness with which the two merchants found it advisable to discontinue their business.

This is but typical of the prevailing conditions in mining as well as other industrial communities today. The Judge Mining & Smelting Company has just moved a stock of goods that it lately has carried for the benefit of its employees to a larger and more conveniently situated store-room in the business portion of Park City, in Utah. Here coupon-books are to be used exclusively. Only employees of the Judge company and its subsidiaries are to be served; in the event of a man leaving the company his book is cancelled and the remaining coupons redeemed. Mr. O. N. Friendly, the general superintendent, has recently added coal to the list of things that can be purchased. He is confident that he will deliver coal in two-ton lots to the homes of his employees at a saving of \$4 per ton over the retail price of the local dealers. This is a considerable item in a country with a winter climate like that of Park City. Mr. Friendly emphasizes the advantages of systematic buying in larger quantity; also he believes that the employees are influenced, perhaps unconsciously, to improve the character of their bill of fare

by being offered good grades of substantial and wholesome food. Shoes are sold at prices 35% below those prevailing in most places. The store is conducted by the company, with no co-operative features, but the prices are only 5% above the wholesale cost and there is no intention on the part of the management to derive profit from the business. In the mining towns of Arizona co-operative stores are numerous. An idea that seems to be popular there is the 'dividend' plan. At intervals of three or six months the accumulated profits are distributed among the employees who are still on the company payroll. Some of this 'dividend' money has come from non-employees who trade at the store, and from former employees who have left the service of the company during the last dividend period and thereby lose their interest in the profits; but most of it is the profit resulting from the purchases that they themselves have made. It would, of course, be possible to price the merchandise so that no appreciable surplus would accumulate, but there is doubtless a satisfaction, psychologically akin to the trading-stamp mania, in getting \$50 or \$100 in a lump sum, even if it is your own money. The deferred rebate, for that is what it amounts to, serves to hold an employee on the job, and from the company point of view, it is desirable on that account. Whatever may be the details of the scheme, the object is always the same, namely to assist the employee by affording him an opportunity to buy many of the things he needs at the price for which the company can purchase at wholesale. Looking back ten or fifteen years, one recalls the company store as a decidedly profitable part of many mining enterprises; indeed, concerning some we may safely say that the net earning from the store, with a monopoly of the trade, even exceeded the profit accruing from the output of ore. We recall a camp in Nevada where there were several independent merchants; the new employee was always advised by his foreman to start an account at the company store. He might be discharged for good reasons, but he was sure to be discharged, if he patronized one of the competing establishments. However, a policy such as this antagonized the men; it was contrary to their ideas of independence. The more progressive managers began to realize that the ill-will created had a bad influence on the employees and that the result was a low morale. Gradually the company store began to be replaced by independent merchants; mining companies frequently encouraged two outsiders to start stores so that there might be competition, with consequent benefit to the employee. Then came the War, with its era of inflated prices, and the contest to keep wages from falling too far behind the cost of eating, sleeping, and clothing oneself. The logic of the situation called the company back into the store business, but on a different basis from that of former years. A bona-fide reduction in the cost of living is equivalent to higher pay; the mining company, by introducing a scheme of organized purchasing and efficient distribution, has avoided the necessity for further increases in wages. A successful commissary represents the application of engineering principles.

DISCUSSION

The Human Factor in Mine Management

The Editor:

Sir—Recently* I had occasion to comment on the important rôle played by the resident manager in determining labor policies in our industrial establishments and the importance of his acquiring a proper background. The fact was emphasized that more and more such managers will be recruited from the ranks of graduates of technical schools who have the responsibility of furnishing that background. This is, of course, conspicuously true in the mining industry. There are some important exceptions where laymen have been put in charge of large mining operations, but this is merely evidence of the defects in the training of engineers to which I alluded.

In the discriminating review of my article that appears in the editorial columns of your September 25 issue, you mention that "the manager of a mine discovers only too often that his directors, even engineers who have developed into successful financiers, are out of touch with working conditions, because these have changed since they themselves were in charge of operations. By living in large cities, by associating with a different class, by lack of contact with working-men the head official of a company lose the ability to understand labor conditions; so that the manager may find himself sometimes out of sympathy with them. They should realize their detachment from the work and give him a free hand."

The very point I wish to make, however, is that the technical manager himself when given such a free hand is only too apt, because of the defects in his training, to prove unprogressive and unskilful in the handling of human beings. There are some directors and executives in large cities, it is true, who, by lack of contact with the working-men "lose the ability to understand labor conditions". On the other hand, however, residents of large cities do have the advantage of contact with what is going on in the world at large, with modern economic and sociological tendencies, and with innovations that have proven successful elsewhere. The resident manager, on the contrary, is isolated and does not have the advantages of such contacts. Unless he has had his broadening training while at a technical school, he may be less liberal in his general outlook, less open-minded in his willingness to try out new methods in personnel management than the financier or head official in the home office. A mining camp is particularly apt to be cut off from the community and this immunity of the resident manager to

outside influences is therefore exaggerated in mining administration.

This very isolation of the mine manager causes him usually to be given more latitude than is given managers in other industries. Thus if he be liberal in his ideas he is apt to be free to institute any progressive policies, he may decide are wise, no matter what the temperament of his head officials. On the other hand, the most liberal board of directors is powerless to initiate a modern program in the handling of labor if it cannot obtain a manager who combines technical qualifications with a grasp of modern methods of getting the co-operation of employees. A certain engineer with an international reputation, both professionally and as a liberal thinker, related to a number of us his experience and that of his associate directors in having to dismiss two or three managers in a certain manufacturing establishment, because of their inability to find one man who combined both these qualities. In conversation with a well-known labor expert who served as labor manager with a large mining company, I was interested to hear him relate the difficulties he encountered in getting the superintendents and general managers of the several plants of that organization to co-operate with him or to adopt the modern methods it was his duty to install.

Let us take a concrete example: Suppose the directors have decided to adopt a modern employee representation scheme. Unless the resident manager is sympathetic and has studied such plans elsewhere, unless he affirmatively wants it and knows how to guide it, it will be futile to introduce it over his head. If, however, the manager desires to adopt such a plan, there is a reasonable chance that the executives at home will not interfere with him. It is true that the whole tone of an organization is largely colored, as is commonly said, by the temperament and attitude of the 'old man on top', but the administrators in the field can exercise considerable independence of action if they have the ability and background to act on their own initiative.

Aside from the relative responsibility of the staff men at home and the manager in the field, mining administration from the top down, perhaps more than any other industrial administration, is in the hands of the engineering profession. As Mr. Hoover with his usual penetration has said in his 'Principles of Mining', written more than ten years ago:

"In these days of largely corporate proprietorship, the owners of mines are guided in their relations with labor by engineers occupying executive positions. On them falls the responsibility in such matters, and the engineer

*The Atlantic Monthly, September 1920.

becomes thus a buffer between labor and capital."

It is indisputable therefore that engineers should not be graduated, as they too often have been in the past, with a rigid notion of the universe. A thorough background in physics, chemistry, mathematics, in mechanics, metallurgy and mining, does not equip a man to act as a "buffer between labor and capital". Some training in psychological conditions and the mental attitudes of men, particularly of unsophisticated men, some knowledge of modern sociological tendencies, some grasp of the incentives that make men act, some acquaintance with the history of trade-unions, and some understanding of the technical side of human engineering would seem to be requisite in the future administrator. Engineering educators must be made to adapt themselves to the new conditions.

It is not only a question of intellectual processes; it is also a question of the "psychological conditions" not in this case of the workmen, but of the engineer himself. As I have previously stated elsewhere, he is apt to become dehumanized by the very intensity of his application to routine study, unless there have been some counter-acting influences, such as working with the men he will handle in his future career, or teaching English to foreigners under the auspices of the Industrial Service Movement of the Y. M. C. A. If necessary, a certain portion of his summer vacation, now utilized solely for geological expeditions, civil engineering, and other practice-work, should be devoted to this purpose.

The disadvantage of a mining engineer becoming dehumanized is not confined solely to his relations toward his future employees. It affects his qualifications in other respects. We must remember that only a very small percentage of men graduated as mining engineers become research specialists. A large proportion become administrators or field consultants. It is therefore most important that his intuitive processes and imagination be not paralyzed. A good mining engineer in making a field examination will necessarily use a certain amount of imagination. I am, of course, not here referring to the extravagant dreams of a promoter. It is a commonplace that all too often this quality of imagination is lacking in mining consultants. It is also important that he retain the qualities of a 'good mixer'. The very nature of the work that he is called upon to do means that his human contacts are of great importance. Very often the value of his observations in the field depends on his ability to get the confidence of certain individuals in a locality. When it comes to administration, a man certainly cannot expect to be successful in his relations with his staff if his emotional processes are inhibited.

To return to the personnel question. If an employee representation system or a shop committee be installed, it takes personal leadership to make it an entire success. If there are relations with trade-unions to be faced, a manager with good human understanding and tact can prevent much friction. If it is important to overcome the objections of drill-men to use 'one-man' in place of 'two-men' drills, only a persuasive manager can do so. Lead-

ership after all is a pre-requisite in securing *esprit de corps* in a mining organization, just as in any other organization, industrial, military, social, or political; and leadership is difficult in the absence of imagination and capacity for emotional interchange. Let me here quote from the statement of a well-known engineering educator, Professor Walter Rautenstrauch. He says, in describing a new course in Industrial Engineering at Columbia University of which he is in charge:

"Within the last few years there have been a great many schemes advanced under the heading of industrial democracy, welfare work, and employment management. While attention will be given to the influence of these movements, care will be taken to point out that no plan . . . can ever take the place of the human basis, upon which industrial enterprises must be successfully managed.

"If the spirit existing between the management and the men is not properly founded, no scheme or method can overcome this defect. The manager must be intensely human . . ."

Of course, there is a great deal in a native capacity, but a native capacity can be spoiled or developed. On the other hand, even taking it for granted that a manager retains a pleasing personality, which equips him for leadership, he is apt to ignore the personnel problem if his professional interest and enthusiasm have been mainly focused upon the physical problems. I know of a case where an engineer-manager with a naturally fine personality for leadership balked at making certain useful experiments along personnel lines because, as he frankly put it, he considered the physical problems of greater importance and did not wish to waste his time on the human ones. Nor could he be persuaded to delegate them to others.

After all, it is not merely a question of a personal success or the advantage of the particular establishment. Engineers, as well as laymen, have a serious responsibility toward society in assisting in the solution of our vexing industrial problem, which many astute thinkers regard as the gravest problem that faces our social system. It is of the utmost importance that the engineer retain his perspective, and, with his traditional objectivity of approach, do not allow himself to be swayed by class intolerance. In his relation to the question of collective bargaining or trade-unions, he should judge the particular situation and decide for himself, undisturbed by any preconceptions, whether the union leaders will assist or retard the welfare of his organization. I cannot here do better than again quote from Mr. Hoover:

"As corporations have grown, so likewise have the labor-unions. In general, they are normal and proper antidotes for unlimited capitalistic organization.

"Labor-unions usually pass through two phases. First, the inertia of the unorganized labor is too often stirred only by demagogic means. After organization through these and other agencies, the lack of balance in the leaders often makes for injustice in demands, and for violence to obtain them and disregard of agreements entered upon.

As time goes on, men become educated in regard to the rights of their employers, and to the reflection of these rights in ultimate benefit to labor itself. Then the men, as well as the intelligent employer, endeavor to safeguard both interests. When this stage arrives, violence disappears in favor of negotiations on economic principles, and the unions achieve their greatest real gains. Given a union with leaders who can control the members, and who are disposed to approach differences in a business spirit, there are few sounder positions for the employer, for agreements honorably carried out dismiss the constant harassments of possible strikes. Such unions exist in dozens of trades in this country, and they are entitled to greater recognition. The time when the employer could ride roughshod over his labor is disappearing with the doctrine of *laissez faire*, on which it was founded. The sooner the fact is recognized, the better for the employer. The sooner some miners' unions develop from the first into the second stage, the more speedily will their organizations secure general respect and influence."

It would be presumptuous to make too definite any suggestions to educators as to how the purely technical education of a mining-man's training should be supplemented. Developing qualities of human leadership and arousing the imagination of students is a subtle process and must be left to individual ingenuity. It is here a matter of stimulating innate qualities. If the student is wholly deficient in capacity for leadership perhaps it would be best to frankly advise him not to follow an administrative career. In any event his interest in human psychology should be aroused by both theoretical work and practice-courses. The Industrial Service Movement of the Y. M. C. A. is furnishing opportunities for students to gain direct contact with industrial workers through teaching English and citizenship to foreigners, and leading technical classes of workmen. It is probably largely a question, however, of the spirit and general approach which permeates the entire course. As suggested in your editorial review, it may be well to have among the instructors men who have had experience in handling workmen successfully.

One concrete suggestion that I would like to emphasize is that the curricula should be revised so that even at the sacrifice of a certain amount of instruction in purely technical subjects an adequate number of hours be devoted to psychology, social economics, welfare work, and the modern technique of handling labor. There is an imposing literature to which mining engineering students should be given an adequate approach. To enumerate at random a few of the more technical subjects which this literature includes: there are the employment, placement, training, and proper 'upgrading' of the worker, individual production records and other methods of arousing interest in work, job-analyses, motion-studies, study of labor turn-over, payment-methods, foremen-meetings, training for foremanship, health, safety, housing, and community-work programs, and shop-committee organization. The main purpose in this connection should be to indicate to the student that such a literature exists, teach

him where he can find the authorities, and, what is most important of all, awaken his professional interest. Thus when he becomes a mine-manager he will take a similar interest in them that he does in technical matters and will be anxious to make sane experiments along these lines. If he has not the time to devote to every aspect of the personnel problems of his organization, he will delegate those which he cannot personally handle to specialists realizing the importance of having no phase neglected.

And last, but not least, the mining engineer should be taught to approach such controversial subjects as collective bargaining and trade-unionism in the scientific and liberal spirit of Mr. Hoover, so that he may not be swayed by mere shibboleths and catchwords.

SAM A. LEWISOHN.

War Minerals Relief

The Editor:

Sir—As the founder of the Pacific Tungsten Company, whose operations were of sufficient magnitude to justify the expenditure of a large sum of money during the late war, which expenditure was a matter for consideration by the War Minerals Relief Commission, I have pleasure in stating that the claim for relief under the War Minerals Relief Act was settled in double-quick time, once the Commission had all the information before it and was in a position to decide the many points of detail with myself, which under no other circumstances would have been settled.

I found the Commission willing to meet my company's claim fairly and squarely, once, as I said before, all the information available was before it. I wish to say here that I found the Commission not only willing but eager to settle the claims. The courteous treatment by this Commission is indeed commendable, and I feel it my duty as president and general manager of the Pacific Tungsten Company to express myself in the above terms publicly.

After understanding the magnitude of the work before the Commission, it is my candid belief that the so-called alleged delays in the settlement of claims are mainly due to the Commission not having before it all of the facts surrounding each individual case, and I do believe that the Commission deserves commendation by the claimant, because the Commission itself is restricted from dealing with certain items included in the claims, thereby creating considerable dissatisfaction to some claimants who have not received what they consider is due them.

My contention is that the purchase of property and leases should not have been eliminated from the claims, neither do I think that the full amount in all cases should have been returned to the claimant through the War Minerals Relief Commission; but I do think that this matter should have been left to the Commission to be dealt with as each case warranted, because it is impossible to produce war mineral unless the lease or property purchase was at some time made, upon which property so purchased, milling and other reduction plants were con-

structed at considerable cost to the claimant, which plant, etc., comes within the range of the Commission for settlement. However, the War Minerals Relief Commission has had all of this eliminated from any consideration by them, no matter what we may claim is our just reward. The War Minerals Relief Commission cannot be blamed for not having the power to consider property purchases and leases out of their jurisdiction.

San Francisco, October 22.

Iron and Steel in India

The Editor:

Sir—Recent discoveries of iron ore in the south of the Singhbhum district would point to the iron-smelting industry of India assuming far larger proportions than at one time seemed likely. At the present only two works of any size are in operation, the Tata Iron & Steel Co., at Jamshedpur, and the Bengal Iron Co., at Kulti. The former now draws its ore from the Gurmaisini hill in Mourbhanj State where the average quality is Fe 61%, P 0.08%, S 0.03%, SiO_2 4%, but has further deposits at Okampad, Badampahar, and other places, some of which are of higher grade but require railway connection before they can be worked. The plant at Jamshedpur consists of three blast-furnaces, open-hearth furnaces, blooming, rolling and bar-mills, sulphuric-acid plant, and coke-ovens, but various extensions to the present plant are now being carried out and subsidiary industries that require iron and steel are springing up around the works. The sulphuric acid used is made from imported sulphur, but the Burma Corporation is erecting works in the neighborhood to treat its zinc concentrate, and so supply India with the acid and spelter she requires for the further development of her industries.

The Bengal Iron Co. after an abortive attempt at making steel from the ironstone of the Barakar and Raniganj series and the magnetites of Singhbhum now confines itself to pig-iron and castings. For this purpose it uses hematite from Pansira and Buda hills near Manharpur in the Kolhan estate and magnetite-apatite ore from Dhalbhum. Some ten million tons, averaging Fe 64%, P 0.05%, Mn 0.06%, SiO_2 3%, are estimated to be available in the first two deposits, but the quantity of the latter is small.

The discovery of the newer deposits has led to the formation of the Indian Iron & Steel Co. with a capital of Rs. 3 crores, which is now erecting works at Asansol on the East Indian Railway close to the coalfields. Various Calcutta firms have taken up portions and the Workington Iron & Steel Co. is also interested in this ore-field. This has led to the Bengal-Nagpur Railway building a branch line 70 miles long from Amda on the main Calcutta-Nagpur line to Jamda in the south of the Kolhan, which should be open to traffic about the end of next year.

According to recent reports, very large quantities of ore, running possibly into thousands of millions of tons, are available, and these deposits have been followed into the neighboring States of Bonai and Keonjhar, where ex-

tensive orebodies were previously known to exist, but have not yet been worked owing to lack of communications. These occurrences are similar to others found in Singhbhum and Mourbhanj, all being associated with the Archean quartzites, phyllites, and slates of the Dharwar series, the iron ore capping the highest hills and ridges of the area and existing as float on the flanks. The average iron content seems to be about 64%, but samples from the better parts of the deposits contained as much as 68% Fe with phosphorus about 0.06% and sulphur 0.02%. Large quantities of both limestone and dolomite are obtainable for flux from the Kaddapah series in the State of Gangpur some 40 miles to the west. These are situated close to the main line of the Bengal-Nagpur Railway and are already being worked by the Bisra Stone Lime Co. and the Tata Iron & Steel Co., while coking-coal, though somewhat high in phosphorus, is obtainable from the Raniganj, Jharia, and Giridih fields.

Firebrick and silica brick are manufactured locally from the Gondwana fireclay and Dharwar quartzites, while chromite and bauxite are both available within reasonable distances. All magnesite, however, has to be imported from the Salem district of Mysore, which also supplies some of the chromite used. The only necessities not indigenous to the country are sulphur and fluorspar, and, though the Burma Corporation will supply the former need, no workable deposit of the latter has yet been found in India. Small quantities are known to exist in Rajputana, Central India, and Burma, but the supply is insufficient even for present needs which amount annually to about 300 tons.

E. F. O. MURRAY.

Asanboni, Singhbhum, India, September 9.

ONLY a large deposit of mica favorably situated with regard to transportation and a grinding-mill can be probably worked solely as a source of scrap mica for grinding. Most mica mines must also yield good sheet mica to make the mining profitable, according to the U. S. Geological Survey. Mica to be of value as sheet must yield rectangles at least one and a half by two inches, which must split easily and evenly, be free from cracks, markings, and other fracture lines, and be reasonably free from specks or foreign mineral matter. The size stated is the smallest rectangular size which is salable as uncut sheet and the rough-trimmed mica sheet must be nearly twice as large to yield the rectangle stated. In order to be profitable most deposits must also contain some mica larger than this. If mica did not usually contain much foreign matter and did not have so many fissures and imperfections—cracks, markings, and holes—there would be no difficulty in obtaining all the mica needed. But there is only a very small percentage of sheet mica which when finally prepared is of the proper quality to be used in the industries. Good sheet mica should be so flexible that a sheet a thousandth of an inch thick can readily be bent into a cylinder one-quarter of an inch in diameter. The production of mica in the United States ranges from 3000 to 5000 tons per year.

THE SALTILLO LEAD SMELTER

Metal Prices and Mining in Mexico

By H. G. NICHOLS

When the world went to war, the extent to which the influence of relativity was to make itself felt upon such time-honored questions as 'What is Ore', was possibly not considered, but to the mining engineer, cherishing utopian dreams in which technical considerations might pertain, unassailed by the demands of sordid finance, the resultant fluctuations in the metal market have brought home the realization of his dependence upon prices, to give a satisfactory and all-embracing answer to this question.

I have been engaged in a Mexican district where I was simply asked to produce ore in sufficient quantity and of a grade in copper, lead, silver, gold, and zinc, that was 'ore' in an accurately economic sense. The mineral products from the various mines were in the form of carbonates and sulphides of copper with a gangue high in lime, carbonates and sulphides of lead and zinc, cupriferous sulphide of iron, and a silicious silver compound. The problem was faced from the dual standpoint of lead and copper smelting, with a side issue in

THE COPPER SMELTER AT CONCEPCION DEL ORO

the shipment of zinc ore. The lead-smelting question was not unduly involved, given the necessity for outside purchase of limestone for flux, and apart from the ever troublous consideration of fine. The copper-smelting side of the operations should have been simpler, as with an abundant supply of pyrite the general mine-product was self-fluxing, and the furnace charge was made up approximately as follows:

From A group,	Copper mines	73.0
B group,	Lead mines (silicious silver ore)	4.5
C group,	Pyrite mines	22.5

The approximate analysis of the run-of-mine from A group was as follows:

Insoluble	32.5
FeO	13.0
CaCO ₃	51.0

and by a process of screening, crushing through a Gates crusher, and sorting on a picking-belt, a shipping product, amounting to about 60% of the original tonnage, was obtained having approximately a composition of

Insoluble	32
FeO	13
CaCO ₃	50

in which the grade of copper was increased about 54%. The run-of-mine from B group had an approximate gangue composition of

Insoluble	30
FeO	16
CaO	3

from which could be separated:

- 1. A zinc product sufficiently clean for shipment.
- 2. A lead product with approximate gangue composition of insoluble 25%, FeO 16%, CaO 3%, with from 1 to 2% sulphur, and containing zinc and silver, with some copper.
- 3. A silicious silver ore with 48% insoluble, 20% FeO, and 2 to 3% CaO.

From C group a pyritic product was produced with a composition of approximately

Insoluble	18.5
FeO	39.0
CaCO ₃	9.0
Sulphur	33.0

and an iron ore containing 8% insoluble, 2% CaCO₃, and 74% FeO.

The disposition of the several mine-products was as follows:

- From A group; entirely to the copper smelter.
- B group; lead ore to the lead smelter, Zinc ore shipped, Silicious silver ore to the copper smelter.
- C group; as required, to both smelters.

The products treated at the copper smelter were therefore:

	Insol.	FeO	CaCO ₃	Sulphur
%	%	%	%	%
73, averaging	32	13	50	..
With mostly oxidized copper minerals containing gold and silver.				
4.5, averaging	48	20	5	..
Containing silver and gold.				
22.5, averaging	18	39	9	33
With some copper, silver, and gold.				

And the average composition of the mixture at this smelter was

Insoluble	29
CaCO ₃	39
FeO	19
Sulphur	8

with copper, gold, and silver contents. The word 'ore' has been avoided so far. In order to keep in touch with requirements for profitable working, the following equation was made use of:

$$P = \frac{(X \times (C + C') - E) \times 100}{\frac{XY}{T}}$$

Where P = percentage of copper in the ore from A group, required to offset expenditure.
X = tonnage of ore from A group shipped.
C = operating mining-cost per ton shipped, that is, cost capable of being regulated by the mining department.
C' = all other costs per ton shipped.
E = value of all outside ores (from B and C groups) smelted = tons of copper contained

Fig. 1

× 82% extraction × current price less \$0.036 per lb. freight and treatment charges on matte + oz. silver contained × 95% extraction - 2% × current price + oz. gold contained × 95% extraction × current price.

Y = value of A group ore shipped (as above).
T = tons of copper in A group ore shipped.

The object being to ascertain whether the grade of ore being shipped was coming up to the standard requirements based on fluctuating conditions. If anyone cares to take the trouble to work out this equation, taking constants for every factor except the price of metals, he will see to what extent the problem of satisfying the demands of profit-earning has been affected by this bugbear.

Assuming that considerations of mining economy have pointed to a 3% product as being desirable and that a monthly output of 10,000 tons shipping ore is required, and that this ore will contain

2.5 oz. per ton silver
0.025 oz. per ton gold

CELEBRATING THE 16TH OF SEPTEMBER

The metal-content of outside ore smelted with the above tonnage might be taken as above, at

Copper	40 tons
Silver	7000 oz.
Gold	55 oz.

and the operating mining cost at \$4 per ton, the smelting and all overhead charges at \$9 per ton.

With these figures the value of *P* in the equation will be represented by the dotted line in the diagram (Fig. 1) for the half-yearly periods named during the years 1916 to 1920, and it will be seen that what was profitable 'ore' at one time was not so at another.

Add to this criterion the difficulty of increasing grade by reason of unsuitability to concentration of the oxidized ore, of limitations to sorting imposed by dessemination of the copper minerals, and percentage of fine material not amenable to picking, in the run-of-mine, and it will be seen how vitally the problem is complicated by any reduction in output such as results from the recurring demands of a country prone to excitement and fiestas, not all of which are so peaceably conducted as the one shown in the accompanying photograph. This is a picture of Aranzazu celebrating on the 16th September the anniversary of the day when liberty was assured to Mexico to be—well—Mexico.

Returning to the subject of the copper-smelting operations, two points are clear from the figures of percentages, namely, first, that there is a large excess of sulphur consumed, this being due to the friable character of the pyrite from group C. By agglomeration in the cement type of rotary kiln, it is hoped to obviate a great part of this loss, which is of the greater consequence in that there is a notable quantity of copper contained in this fine product. As at present, the method adopted is to bed-down this fine pyrite with fine from group A and flue-dust, and run a low-grade matte from this charge, re-smelting the mixture with coarse ore from the shipping product. The second point is that there is evidently a constant demand for the silicious silver ore from group

B, for fluxing purposes, but to the extent, dependent upon the value of the silver content, that a higher proportion of silica would be desirable. So that here again the question of price of metal comes in, and the smelterman has to temper his technical aspirations to the possibilities extended by a capricious metal market.

The iron ore from group C is not figured in the charge percentages. Smelters have need of tonics as much as human beings. It has been seen that the sorted lead ore from the company's mines delivered to the lead smelter has an approximate composition of 25% insoluble, 16% FeO, and 3% CaO. With the pyrite and iron from C group, this ore comprises from 70 to 80% of all the ores smelted. Limestone, of which there is an abundant local supply, is purchased outside, and the slag has an approximate composition of

Insoluble	%
FeO	32
CaO	20

The introduction of the pyrite is in relation to the saving of the copper content of the B group ores, the ultimate products from this smelter being a lead-silver bullion carrying from 3 to 3.5 kilo. silver per ton and a copper-lead-zinc matte of an average composition of

Copper	%
Lead	15
Zinc	20
	10

which is shipped to refineries. This matte also carries about one-third of the per-tonnage content in silver of that carried by the lead bullion.

All ores are bedded and damped before charging, and the fine, which is shipped as such to the smelter, is agglomerated in a rotary kiln, as above mentioned, without previous damping. In this connection, an interesting incident comes to my mind from years ago. Casting about for adaptations of the principle of dewatering by means of assisted slime-settlement, I was attracted by the possibility of cutting down the cost of cement-making by reducing the percentage of moisture in the slurry before

passing it through these same rotary kilns, and the Portland Cement Manufacturers afforded me facilities for the erection of an experimental plant for this purpose at their works in England. The reduction of the moisture was easy enough with this ideal material, but it transpired that the satisfactory agglomeration of the cement-forming slurry was unfavorably affected by introducing it into the kilns in a state of too high consistence. It is hardly probable, however, that the demands of agglomeration of ore would run on parallel lines to those obtaining in the process of cement-making.

In the B group ore, treated at this smelter, the zinc content is often as high as 10% and is sometimes higher, resulting in matte-forming difficulties and other troubles. The use of the Darby tube type of hood with an annular charge-space of 20 inches is found beneficial as a deterrent to the formation of wall accretions in the furnaces, by keeping the coarse material toward the centre. It may be gathered from the foregoing that this smelter is run for the purpose of producing lead bullion as such, and not as a producer of silver-lead bullion, in which the lead would act more particularly as a carrier, and the extent to which this principle is followed is dependent upon many factors, not the least of which is, again, the price of silver. It has been seen that high-grade silver ore at present is diverted from the B group of mines to the copper smelter, the reason for which is that the high silica-content of this ore is a desideratum at this smelter, while in the lead smelter it would only entail the loss of lead. If there were no copper smelter available, then this silicious silver product would be a drug on the market, because its silica content would entail a greater loss of lead in smelting than the value of the silver would compensate. With a higher silver-value, it is conceivable that the lead might be relegated to the status of a carrier and a certain loss in that metal might be justified.

The point is still further emphasized by the possibility of change in the character of the ore as further depth is attained in the mines of this district. Already a mixture of lead, zinc, and copper sulphides has been found in the mines of A group, and the question of what can be considered as 'ore', profitably to be treated, in either lead or copper furnaces, may depend largely upon the results to be obtained by water concentration and the relative market-value of the metal constituents of each product. In such a case, who can say to what extent the price of metals might determine the distribution of the mine-products and the principles upon which the schemes of treatment would be affected to the end that the definition of profitable ore be established.

THE Alsatian potash deposits extend between Mulhouse, Cernay, Soultz, and Ensisheim, with a total area of 124 square miles and an average thickness estimated at about 14 ft. 9 in., with an estimated tonnage of 1,472,000,000 metric tons of salts containing 300,000,000 metric tons of potassium oxide (K_2O). The deposits are 14 miles long and 6 miles wide, east to west. The basin has been affected by the formation of the Rhine val-

ley, and it is thought to be a result of the lagoon state of the region during the Oligocene period. The potash layers are in the centre of a salt formation in two parallel layers, the upper one being 1 ft. 3 in. to 3 ft. 9 in. thick, averaging 25% potassium oxide and the other one, 65 ft. deeper, 11.4 to 13 ft. thick, averaging from 17 to 25% of potassium oxide.

What She Thought

Lawrence F. Sherman writes in 'Forbes Magazine': John (a bricklayer) and Mary, his wife, were seated at the breakfast table in their cozy home on Berger avenue in Pittsburgh, Pennsylvania.

John had attended a meeting of the Bricklayers' Union Local No. 0964 the evening before, and as he swallowed the last drop of Java he remarked to Mary:

"Did you ever hear such nonsense? Up at the hall last night Delegate Brown told us the 'Big Four' of the Farmers' Organizations, with some 5,000,000 farmer members, have declared against strikes and are only going to raise enough food to eat themselves. Why, Mary, if they should only grow enough for themselves—the people in the cities like us would starve!

"When Brown stopped talking almost everybody in the hall wanted to speak. In the end they passed a vote that 'the farmers had no such right to cut down their production of food products and refuse to supply the wants and needs of us people'. That is what we did, and every local throughout the country will do the same."

Mary's eyes were flashing as she spoke: "Maybe you're right, John, but I don't see why the farmer hasn't as much right to refuse to work from dawn to dark as you have. When we first came here a few years ago and before you joined the union you used to lay 1500 to 1600 bricks a day and got \$3.50, and everybody had a place to live in. After you joined the union it didn't allow you to lay so many bricks, and every little while you were home on strike for shorter and shorter hours, and now you can work eight hours in a day and the union will fine you if you lay more than 400 bricks a day. Just think of it, John, and all the people that can't get houses to live in because you and all the other union men are not building as many houses as you ought to.

"Of course, you get \$9 a day now, but it costs so much more to live we can't save any more than we used to do.

"No, John, the trouble is not with the farmers. All you union men have gone plumb crazy. You won't work yourselves or allow other men to work as you ought to do, and the farmer can't get help to raise food. The trouble is with yourselves, and, take it from me, if you and all your friends up at the hall don't get busy and change your tune from: 'Strike, strike, STRIKE!' to 'Work! work! WORK!' in mighty quick order we sure will starve."

John looked kind of puzzled as he rose to go.

"Good-bye, John, and don't forget to bring home some seeds tonight so I can have a garden to keep the children and me on."

THE MINE, THE MILL, AND THE CYANIDE PLANT AT THE EXTREME RIGHT

The Mine and Mill of the Belmont Shawmut Mining Company—II, The Mill

By ARTHUR B. PARSONS

When the Belmont Shawmut company acquired the property two treatment plants already existed. The first was equipped with 100 stamps, amalgamating plates, and vanners for gravity concentration, while on the opposite side of the canyon was a chlorination plant where a limited quantity of concentrate had been treated with some success. The new company decided to remodel the concentrator to produce a high-grade product for shipment to the smelter without local treatment. However, the remodeled plant had not been in operation long when freight and treatment charges began to climb, and certain penalties were imposed by the smelting company, so that the cost of marketing became prohibitive. Taking into consideration the discounted price at which the gold was paid for, it cost practically \$16 per ton to realize on a \$60 concentrate; and since the concentrating ratio was 9:1, this added \$1.55 per ton of ore to the cost of operation. Accordingly it was decided to utilize the roasters in the old chlorination plant in the furtherance of a scheme for cyaniding the concentrate. Exhaustive tests made by the metallurgical staff demonstrated the practicability of such a treatment, and determined the details of the process. The chlorination plant was remodeled, and cyanidation was commenced early in 1920. The result has been satisfactory in that bullion has been produced at a gross cost of approximately \$4 per ton of concentrate as compared with the \$16 required under the former plan. Of this gross deduction one-fourth, roughly, is the cost of treatment and three-fourths is the unrecovered gold in the tailing.

The combined gravity and flotation concentration will be described first. The average ore as it comes from the mine contains approximately 7% sulphides, mostly py-

rite, with which is associated gold to the value of \$5 per ton. The small proportion of free gold follows the sulphide in milling so that the problem is essentially to separate the pyrite from the gangue, which, besides silicious constituents, contains dolomite and a considerable proportion of talcose minerals.

Under normal conditions, 400 tons of ore crushed to pass a 2-in. ring is delivered daily, directly from the mine-cars, into a 2800-ton flat-bottomed bin behind the stamp-batteries. See the accompanying flow-sheet. There are twenty 1250-lb. and fifty 1050-lb. stamps, the lighter being fed by suspended Challenge feeders, while platform feeders of Challenge type supply the 1250-lb. stamps. The mortars were manufactured by the Union Iron Works and are placed on massive concrete mortar-blocks with a $\frac{1}{4}$ -in. rubber pad intervening. The mortar-block for the entire 70 stamps constitutes a monolith. The liners of the mortar-boxes are of cast-iron; the front liners are one inch thick and last four months; the back ones, $1\frac{1}{4}$ in. thick, last six months; while the one-inch end-liners also have a life of six months. Dies are likewise made of cast-iron, whereas the shoes are of hammered steel. The stamps drop a height of six inches, 112 drops per minute, and crush seven tons per stamp through a Tyler 10-mesh steel-wire screen. The screen is 14 by 52 in. and the height of discharge is two to three inches, the product being almost entirely 14-mesh and under, with a pulp-ratio ranging between $4\frac{1}{2}$ and 5 parts of water to one part of ore. The stamps, in batteries of ten, are belted with 16-in. six-ply rubber belts to a line-shaft that may be run alternatively by a 7-ft. Pelton water-wheel or by a 200-hp. General Electric induction-motor operating under 440 volts at 450 r.p.m. Power from the water-

ing. The attempt was first made to keep the pebble-load at the centre of the tube; to do this it was found necessary to feed new pebbles at a rate of approximately 1.3 lb. per ton of ore. Considering the softness of the ore, this seemed to be high. Accordingly, the size of the pebble-charge gradually was decreased and it was found that as it diminished the quantity of new pebbles needed to maintain a given load also diminished. There was no impairment in the results, although the consumption of power increased. Apparently several hundred pounds of pebbles were being worn out daily by useless grinding on each other and on the lining when the mill was more heavily charged. A constant load carried 10 in. below the centre was decided upon as being the most economical with respect to all factors. The slime overflow from the second Dorr classifier already mentioned is the feed for the flotation machines. It has a dilution of five parts of water to one of solid, a typical screen analysis being as follows:

	Mesh	%
On	48	4.0
Through	48	11.0
"	65	10.0

There are nine standard Jones-Belmont flotation cells built in a single unit of reinforced concrete. Four cells, arranged in series, form two parallel step-like rows, while the ninth, at the bottom of the flight and at the centre, is a cleaner-cell. The Jones-Belmont machine combines the mechanical and low-pressure air principles of producing froth. The impellers are revolved at a speed of 350 r.p.m. by means of a belt-driven mitre gear running in oil; the air, with a pressure of three pounds per square inch, is introduced through special woven blankets made by the Filter Fabrics Co. of Salt Lake City. The blanket is reinforced on the under side by a $\frac{1}{4}$ -in. mesh iron screen fastened with copper rivets. It seems strange that the screen backing is not placed above, rather than below, the mat, since the greater pressure is from the air-chamber. The froth from the first cell of each series and that from the cleaner flows to the pit of a 54-in. Frenier sand-pump and is thence raised to the extra Buchart table for cleaning while the concentrate from the six intermediate cells flows by gravity to the cleaner, which, in addition to a froth-concentrate, produces a middling that is returned to the second Dorr classifier from which the coarser particles are sent to the tube-mill for re-grinding. Tailing from all but the cleaner-cell gravitates to waste.

The oil used is a mixture of three parts by weight of No. 2 Cleveland Cliffs wood-cresote and four parts of Californian fuel-oil from the same tank that supplies fuel for the roasting-furnaces. For each ton of ore stamped, $1\frac{1}{2}$ lb. of this mixture is added to the tube-mill circuit. Pine-oils and other more expensive oils were experimented with, but results were not materially improved.

The use of sodium sulphide, however, is vital to the success of the flotation. The cleanest tailing that can be obtained from an ore assaying 3 oz. per ton without the use of sodium sulphide contains approximately 0.045 oz. of gold, even when given a double treatment. The same

pulp, to which sulphide in the proportion of 0.50 lb. per ton of ore has been added, can readily be impoverished to 0.01 oz. gold, with the production of a decidedly cleaner concentrate. At the present time 0.25 lb. of 60% sodium sulphide is added, part to the pulp entering the cleaner-cell and part to the tube-mill. At the start 1.5 lb. was introduced, along with the oil, at the tube-mill. However, when the cost of the reagent jumped from 3c. to 10c. per pound, some way of decreasing this amount was sought. The theory on which the addition is made at the cleaner-cell instead of at the tube-mill is this: One function of the sodium sulphide is to flocculate the sulphide particles, at the same time that it deflocculates the gangue; the proportion of gangue in the pulp entering the cleaner-cell is small compared with that in the tube-mill circuit; accordingly, a greatly reduced quantity of sodium sulphide will have an equivalent opportunity to come in contact with sulphide particles to form nuclei for floatable flocks. Since the tailing from the cleaner-cell is returned to the tube-mill a certain proportion of these nuclei enter that circuit and in due course perform their function in the four-cell series. The idea is that a nucleus once formed builds up without further aid, but that the sodium sulphide initiates the structure. Whether or not this is the real explanation, or part of the real explanation, the fact remains that a saving of more than one pound per ton of ore has been effected. The sodium sulphide also has a scouring effect on the valuable mineral particles that stimulates the selective action of flotation.

Air for the Jones-Belmont cells is supplied by a General Electric centrifugal compressor, type T, form A, with a speed of 3450 r.p.m.; a 30-hp. direct-connected induction-motor operating at 220 volts, drives the compressor. This machine has a capacity of 1000 cu. ft. per minute at a pressure of three pounds and could supply 12 cells, instead of nine, if required.

The flotation concentrate amounts to 13 tons of \$25 grade, still based on a daily mill-run of 400 tons per day. As mentioned before, this product is elevated by a Frenier sand-pump, which, incidentally, has performed its work to date with no repairs other than re-packing, to a Buchart table, for an additional separation. This step is necessary principally because of the talcose minerals, which naturally are inclined to float mechanically with the flotation concentrate. Three products are made, namely: two tons of sand assaying \$60 per ton; two tons of intermediate product, chiefly tale, which contains \$2.50 per ton and is discarded; and nine tons of slime worth about \$25 per ton. The first concentrate joins the regular table-concentrate and goes with it to the three collecting-tanks and thence by way of the aerial tram to the roasting-plant. The slime-concentrate flows by gravity to the bottom of the canyon and is then relayed by motor-driven centrifugal pumps up the hill, where it is cyanided. The flotation tailing averages \$0.52 per ton, making a net recovery by concentration of nearly 90%. The power consumed in the entire concentrator amounts to 19 kw-hr. per ton of ore milled and is distributed approximately according to the following table:

Department	%
Crushing and conveying	6.8
Stamping	49.8
Tube-milling	17.1
Concentrating-tables	2.6
Elevating and separating	6.0
Dewatering and excavating	1.7
Flotation	14.9
Lighting	1.1

The mill crew consists of 14 men, including:

- 1 superintendent,
- 2 repairmen (general),
- 2 repairmen (on stamps),
- 3 battery-men (on shifts),
- 3 concentrator-men (on shifts),
- 3 flotation-men (on shifts).

Although the mill was remodeled it does not have the incongruities of some old plants; the arrangement of the equipment is convenient and compact. The concrete foundations are exceptionally good and the mechanical condition of the equipment is first-class, as is evidenced by the small number of operators and repairmen required.

The concentrate-treatment plant was remodeled in a hurry and is a make-shift in some respects. Roasting is done in two old Edwards No. 2 simplex roasters, 56 ft. long, run by small individual Pelton water-wheels. Each has 15 rabbles, the three near the discharge end being cooled by water circulating within them. Fuel-oil is used for firing, the present burners being of home-made construction, although it is planned to change to a low-pressure burner of the style made by the Denver Fire Clay Co. for use in assay-offices and refineries. The concentrate is fed at the rate of 6 to 7 tons per furnace per day by means of an improvised Challenge feeder. The sulphur content of the feed is 30%, while the roasted material, or 'calcine', as it is called, contains, on an average, 4.3% total sulphur, 1.2% of which is combined in the form of soluble sulphates.

The calcine is discharged into a steel car and is trammed to a bin that feeds an inclined plow-conveyor, which performs the double function of cooling and elevating the hot material. The bed is a plane inclined about 35% from the horizontal, 6 ft. wide and 75 ft. long. It is surfaced with bricks that are grouted with cement. Four sets of plows are dragged up the incline by means of two endless chains, one on either side; on the return, the inverted plows travel about three feet above the plane. This arrangement is a relic of days when chlorination was employed, but nevertheless it serves usefully in the present plant. If it is attempted to wet the calcine when hot, steam is formed and dust rises in dense clouds, whereas after cooling there is a rather remarkable absence of dusting when the calcine meets the stream of raw slime-concentrate at the top of the incline. After being pumped to the treatment-plant this slime is partly dewatered in a Dorr thickener before being elevated to join the roasted material as it flows to the Devereux agitator-vats. There are six of these, each 14 ft. high by 14 ft. in diameter. The Devereux agitator consists of a blade exactly like an ordinary boat-propeller, about 30 inches in diameter, on the lower end of a suspended vertical shaft revolving at 125 r.p.m. The propeller, or more

properly the impeller, clears the floor of the vat by 2½ ft., but, except for some accumulation of heavy sand at the periphery and a small cone just beneath the blade itself, the revolving pulp sweeps the floor clean. A single diametrical baffle, consisting of a 2 by 10-in. plank with its low edge two inches below the surface of the pulp, when not in motion, prevents the pulp from overflowing the vat by deflecting the vortex caused by the rotation of the impeller. The result is a thorough aeration of the pulp by the air sucked in.

The Devereux agitators are equipped with a hinged-pipe decanter by means of which water or solution can be removed from above the settled pulp. The operation is intermittent, by charges, a typical cycle being as follows: The pulp, comprising the mixed raw and roasted concentrates, is run into a vat serving as a collector. After the excess water is decanted, sufficient lime is added to make the charge distinctly alkaline; strong barren cyanide solution is then introduced and agitation commenced. This is continued for 16 hours with the addition at intervals of the necessary sodium cyanide and lime to maintain a solution strength corresponding to one pound of cyanide and 1.5 lb. protective alkalinity per ton. At the end of the 16-hour period the charge is allowed to settle and 35 to 40 tons of solution is decanted to the gold-vats. This requires three or four hours. Following this come five 4-hour periods of agitation alternating with settling and decantation, and if the quantity of stock solution is low, a water wash may follow. The following table, showing the results of a typical charge, indicates a rapid dissolving of the gold in the early part of the treatment.

Decanted solution, tons	Period of agitation, hours	Solution assay, gold (heading)	Pulp assay gold, \$60.28
39	16	\$9.16	...
38	4	2.79	...
40	4	1.03	...
35	4	0.43	...
40	4	0.21	...
(Tailing washed)	3.12
(Tailing unwashed)	3.50

Lead acetate is added to the agitators, the average amount being ¼ lb. per ton of concentrate, while the consumption of cyanide is approximately 1.4 lb. per ton of concentrate.

Before starting a new charge, a strong solution of ferrous sulphate is used to 'kill' any cyanide in the residual solution or pulp. This precaution is necessary because the gold in the roasted concentrate is attacked almost instantly even by an extremely weak solution of cyanide and an appreciable amount of gold might be carried away with the decanted wash-water. Tailing from the agitator-vats gravitates to the slime-tailing pond.

This successful treatment by cyanide of unroasted raw flotation concentrate mixed with an equal quantity of roasted table-concentrate is noteworthy. An extraction of only 60% with an increased consumption of cyanide is obtained on raw slime-concentrate alone. Calcined material cyanided alone yields 90 to 92%, whereas the treatment of the two combined results in a recovery of 91 to 94%. The improved extraction as compared with that obtained from treating straight calcine is easily

accounted for by the mechanical advantage of having an intermixture of slime with the granular concentrate. This simply promotes better contact of the solution by tending to keep the sand particles in suspension. Just why the combination treatment affects the additional recovery of the gold in the flotation concentrate has not

to afford as much time as possible for the settling of any suspended solid matter. At present there is no other provision for clarifying, but this is to be remedied, with an anticipated improvement in the behavior of the precipitating press. This is a 12-frame 52-in. Merrill press through which the solution is forced by a two-inch Krogh enclosed-type centrifugal pump instead of by the usual plunger-pump. Merrillite, a combination of dusts of zinc and lead, is fed to the precipitating line by means of a traveling belt actuated by an ingenious contrivance in which an old vanner-head is used to get an appropriate reduction in speed. The cloths become choked rapidly and the pressure goes to 15 or 20 lb. before the leaves have barely started to fill. If proper clarification does not remedy the difficulty an explanation will be sought elsewhere. This Krogh pump is direct-connected to a 7½-hp. General Electric induction motor, while a similar pump that lifts the barren solution from a 10 by 14-ft. tank is connected to a 5-hp. Westinghouse induction motor.

Refining is done in a melting-furnace made by the Denver Fire Clay Co. and fitted with that company's low-pressure burner. A small centrifugal fan, driven by a 1½-hp. motor, supplies the air required and comes as part of the regular equipment. The furnace takes a No. 125 graphite crucible and is tilted with the crucible when pouring is to be done. Bullion less than 600 fine is made at present, but this may be improved when the faulty precipitation is corrected.

Until two years ago operations depended entirely upon water power. For ten months in the year an adequate supply, with a head of 1100 ft., was obtainable. However, work was practically at a standstill for two months during the dry season in September and October, and this interruption was costly. Electric motors were accordingly installed, although many of the water-wheels were retained as alternative sources of motive power. Since then the shortage of water has made the use of electricity increasingly important, so that the installation of the motors was fortunate. Electric power costs \$6.95 per hp. month, as compared with \$2.06 for that developed by the wheels, so water is used whenever available. As mentioned before, the line-shaft in the mill may be run by water; likewise the main mine-compressor in the mill-building is alternatively belted by a 26-in. endless double-leather belt to a 200-hp. General Electric motor, or connected directly through a flexible leather coupling to a 7-ft. Pelton water-wheel. This compressor is an Ingersoll-Rand Imperial Type 10, two-stage machine, having cylinder dimensions of 22 by 16 in. and 13 by 16 in. A duplex Giant air-compressor made by the Compressed Air Machinery Co. is used as an auxiliary. It has no motor, but is driven by a 1½-in. endless manila-rope from a 6-ft. Pelton wheel.

The present predicament of the producer of gold is indicated by the following figures, which show the actual unit increases in the various elements comprising the cost of operation, both mining and milling, in 1920 as compared with 1917. The cost in 1917 was, of course,

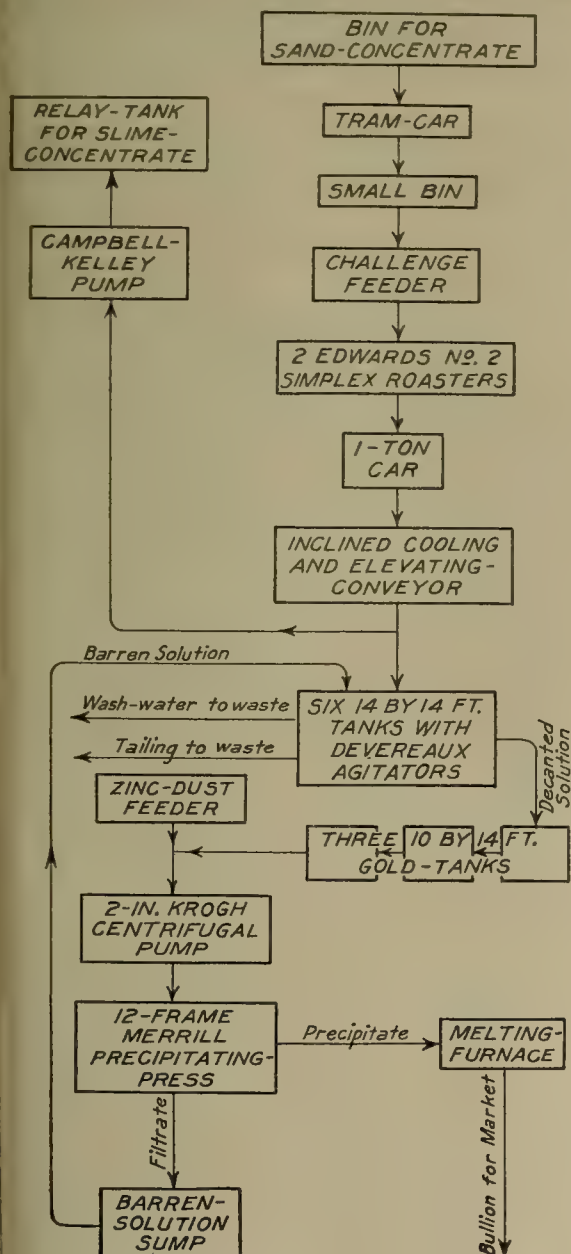

FIG. 2. FLOW-SHEET OF CYANIDE PLANT

been entirely explained as yet, but experimental work on the problem is being done. The part played by the oil is interesting, but it is apparent that some combination of conditions renders it harmless in this particular plant.

The decanted pregnant solution runs to the first of three 10 by 14-ft. gold vats, connected in series in order

far in excess of that in 1914, which we consider as 'normal'.

	Proportion of total cost	Increase 1920 over 1917
	%	%
All labor	60	55
Principal supplies	33	34
Power	7	57
Total	100	48.21

The superintendent at the mine, to whom I am indebted for the data presented in this article, is O. McCraney. C. W. Wark is mill-superintendent and Byron E. Rowe has charge of the mine. Albert Silver, consulting metallurgist, supervised the experimental metallurgical work, while the general direction of the enterprise devolves upon Frederick Bradshaw, general manager for all of the Belmont companies, whose office is in San Francisco.

Use for Blast-Furnace Slag

The Germans during the War, when materials were scarce, gave a great deal of attention to the utilization of blast-furnace slags. 'Nature' states that a new use for slag is foreshadowed in Germany, that is, for the manufacture of light bricks for building purposes. By passing molten slag horizontally through water, the steam generated blows out or extrudes the slag-jet, and forms what the Germans term 'spume' slag or artificial pumicestone. This material has been patented under the name of 'thermosite', owing to its excellent heat-insulating properties.

The patentee has also invented a press for pressing bricks formed of small pieces of this artificial pumice and a mixture of slag, sand, and slaked lime which is used as a binder. The bricks thus formed are strong and light, and resemble in their properties the tuff obtained in the neighborhood of Andernach. As in addition they can be pressed to large dimensions, less mortar will be required

in building operations. The German authorities have approved of the new type of brick for house-building.

Gold and Silver Production of Ontario

*Ontario's position as a producer of gold is becoming increasingly important. For the first half of 1920 the output was nearly 22% greater than the 1919 production. Production of gold by individual mines is presented herewith:

Porcupine	
Hollinger	\$2,928,079
McIntyre	1,085,298
Dome	989,586
Porcupine Crown	70,017
Dome Lake	46,809
Northcrown	31,019
Davidson	13,489
Kirkland Lake	
Lake Shore	243,977
Kirkland Lake	137,676
Teck-Hughes	125,137

From miscellaneous mines the output was \$17,138, of which the Argonaut in Gauthier township contributed \$13,938. There was also a recovery of gold worth \$2498 from nickel-copper refining operations. In addition gold mines produced 49,156 oz. of silver worth \$56,364. During the period 673,694 tons of ore was milled—the milling capacity at Porcupine at the end of June was 5296 tons and at Kirkland Lake 330 tons daily.

During the period a total of 4,474,322 oz. of silver worth \$5,077,028 was marketed. Of this total 225,513 oz. came from the Miller Lake, O'Brien, and Castle properties at Gowganda, 23,414 oz. from nickel-copper refining operations and 49,156 oz. from gold ores. Some producers of silver were paid for the cobalt content of ores, concentrates, and residues marketed. In all \$138,317 was received for 296,116 pounds.

*Ontario Bureau of Mines.

Mineral Production of Arizona in 1919

A Judge on Experts

On August 27, in an apex suit between the Northport Smelting & Refining Co. and the Lone Pine-Surprise Consolidated Mining Co., involving extra-lateral rights in the Republic mining district, the Federal Court (Judge Rudkin) engaged in a colloquy with counsel, William E. Colby, of San Francisco, on the subject of geological experts. We take the report from the official stenographic record.

MR. COLBY: Our contention is that when a vein crosses a side-line, the burden is immeasurably increased to prove that a faulted vein of this sort turns at an angle and comes across the end-line.

THE COURT: According to your own conception, all this expert testimony is valueless and largely speculative.

MR. COLBY: No, I think we could not get along without it. We could not have had a trial without it.

THE COURT: But it proves nothing substantial.

MR. COLBY: I don't understand Your Honor.

THE COURT: As to where the Black Tail vein begins or ends, or whether it intersects the other line, or stops before it gets there, all of this is a matter of speculation, notwithstanding four days have been spent in taking testimony.

MR. COLBY: In all of these cases there is, we have to admit, a great deal of speculation on both sides, and it is really a case in which speculation is unavoidable. I would be the last person in the world to say that experts were not of value to us.

THE COURT: I did not mean to imply that, but I say, so far as the question of whether or not these veins go on through, or whether they stop at the fault, or so-called fault, it is largely speculative.

MR. COLBY: We have to take the testimony. If we could look into the ground, and have the insight of a prophet, of course, we might tell where these veins were, but the best we can do is to take what the experts tell us and judge from that. They agree on most facts, but when we get into the realm of dispute—

THE COURT: They agree on facts that are not material; but when they are material, they differ.

MR. COLBY: I think there is something to that, and yet I do not think it quite fair to the experts, because I don't think any of these experts would—

THE COURT: I didn't accuse any of them of lying. But I do know that they testify for the man that brings them. They may be brought for that reason, or they may testify that way because they are brought. I don't know what the reason is, but I am discussing only the ultimate facts.

MR. COLBY: They have the liberty of refusing the service, and I believe that these experts here, most of them, would refuse to testify in a case that they did not believe in.

THE COURT: I have no information on that at all.

[In the afternoon of the same day, at the close of Mr. Colby's argument, the Court reverted to the subject, as follows.]

THE COURT: I might say by way of explanation, Mr. Colby, you apparently misunderstood my reference to expert testimony. I had reference exclusively to conditions that existed at the agreed point of intersection between these two veins, and it was entirely a matter of opinion with all the experts as to what transpired at that place. They were in doubt as to whether there was an intersection at all, whether the Black Tail vein even extended to that point; and, of course, if they were in doubt as to that, they must necessarily be in doubt as to whether it extended beyond. I consider the testimony very unsatisfactory on that point on both sides, and I think it is largely a matter of opinion. The experts in this case were extremely candid and very truthful, so far as it related to the physical facts. I never saw less conflict in a case in my life. I will say that much in their behalf.

MR. COLBY: I am very glad to hear that, because I may say that all the experts on both sides felt very sorry to hear Your Honor's comments, because they took them as a personal matter.

THE COURT: Well, it was not personal at all. I had reference solely to the point you were discussing. You were expressing a doubt as to whether the Black Tail ever reached that point or not, and I think the testimony will substantiate that doubt; and then I said that their opinion as to whether it went beyond there was a mere matter of speculation.

MR. COLBY: I appreciate that, as I feel that they interpreted Your Honor's actions as an endeavor to point out to them—

THE COURT: Well, if you will recall, you were discussing the question as to whether the Black Tail ever extended up there at all or not.

MR. COLBY: Yes, that is very true.

THE COURT: And that is entirely in conflict with the idea that it extends beyond.

MR. COLBY: That is true, I agree to that. That is, we are in a state of uncertainty there because there is some vein that extends up. It has some of the characteristics of the Black Tail; it is in a location somewhat near where we would expect to find the Black Tail. The Black Tail goes on in another direction, we don't know where, and it has not been disclosed.

THE COURT: Yes, I realize that.

MR. COLBY: I feel that in such cases as this experts are the only means by which we can understand a situation of that sort. Your Honor can appreciate that if you and I and other counsel should go in there and try to determine what occurred there, we would be at sea. And while the common miner is given high praise, and justly so, in many cases, of course, they are at variance with the scientific facts; and it is only through the experts that we can reach an understanding of these things. As I pointed out in a series of articles which I wrote, this is a defect that is inherent in the law, in the manner in which we try these cases. When you hire men on opposing sides, who are supposed to go underground and ascertain the truth, and they are employed to find the truth, they

naturally and usually lean toward their employers. They could not do otherwise and remain human beings. And when they get into court they have their conflicts, which come about between all opposing witnesses, or witnesses on opposing sides. And yet they do, with entire fairness, try to be impartial. I would not believe of Mr. Simpkins or Mr. Searls that they would stultify themselves in any way. And so I am very glad to hear Your Honor express that view, because all of us misinterpreted your remarks.

THE COURT: I am very sorry they did, because I had an entirely different thought in view.

MR. COLBY: I was sure that you did, because I remember reading in one of your decisions—I think it was Judge Hawley's—who expressed the very highest regard for experts (after practically a life of litigation) that had been called before him in mining litigation. He was referring to mining experts, and he said according to his lifetime experience he had never met with men whom he felt were more zealous to get at the truth, knowing of course that they were handicapped by being employed on opposing sides, but he never, with one or two exceptions, knew of that class of men who would knowingly and wilfully tell an untruth in his court-room. And I felt Your Honor had the same belief.

THE COURT: Certainly.

Geologists as Expert Witnesses

By F. L. RANSOME

*The fundamental difficulty as regards the present system of taking expert testimony appears to lie in the antithetical relation that exists between the scientific and the legal attitude of mind. The life of a scientific man is or should be devoted to the search for truth and, what is just as important, to the promulgation of truth. He should subject all evidence to the most critical and impartial scrutiny and be constantly on his guard against becoming an advocate, even for his own conclusions. Tradition and precedent have no weight with him, and authority, although entitled to respect when founded on observance and mastery of the principles of scientific method, does not bind him. The lawyer, on the other hand, while his intellectual integrity may be unimpeachable and while he may employ the methods of science in certain branches of his profession, is, in ordinary practice, an advocate. It is his business to win the case for his client and his efforts toward that end consist largely in a search for precedent in the form of prior decisions. He is confessedly and properly a partisan and searches for those facts that will help his case. He may also seek for those facts that are opposed to his client's contention, not, like the scientific man, to make them known, but to arm himself against their possible introduction as evidence by opposing counsel. In other words, he may earnestly seek the truth but it is not necessarily his purpose to speak the truth, the whole truth, and nothing but the truth. His endeavors in every way possible to

create an atmosphere favorable to the contention of his client and to play upon the feelings as well as the reason of the jury. These two attitudes of mind are so diametrically opposed that it is rather remarkable that practising lawyers, when raised to the bench, should be able to adjust their mental processes to the judicial attitude.

In view of the fact that many eminent and honorable men of science have accepted positions as expert witnesses, it is not justifiable to assert roundly and without qualification that such acceptance was morally wrong. Certainly the intent of wrong-doing has usually been absent and many such witnesses may have been thoroughly convinced of the inherent righteousness of the cause espoused. Nevertheless, I believe that it must be admitted that the geologist who becomes an expert witness for one side in mining litigation places himself in a scientifically false position.

Recently, in an interesting paper, Augustus Locke has suggested† that mining geologists so-called, might be divided into two professional groups—'court geologists' and 'ore-hunting geologists'. He points out that the mental qualifications for the two branches of the profession are not the same—that the court geologist must have the mind of an advocate, whereas the ore-hunting geologist should have the judicial temperament. He cites the *Elm Orlu v. Butte & Superior* lawsuit of 1915, in which five eminent geologists on one side were unanimous against five equally eminent and unanimous geologists on the other side, both as to matters of fact and to inference or opinion. He puts the case as favorably as possible for the expert witnesses when he maintains that this unanimity in difference, so little creditable to science, involves no personal dishonesty. He explains it by unconscious prejudice.

Perhaps there was no dishonesty in the ordinary moral sense: perjury is a harsh word. But if it be considered that the difference sprang from unconscious prejudice, is there not a more subtle intellectual honesty that is violated when a scientific man, with the example of this and other cases before him, permits himself to be placed in a position wherein he knows he may have to be consciously dishonest or is at best likely to interpret facts through the spectacles of prejudice? It is admitted that such work is not only profitable but is often intensely interesting, and may give opportunity for scientific observations of value. The temptation to engage in it may be very strong. Can a man who cherishes the highest ideals of scientific work afford to yield to it, under the existing practice of employing expert witnesses? Opinions on this question will differ, but my own belief is that in general he cannot. It has been said that a witness before he undertakes a case may be sure of his ground. As a rule no geologist can tell in advance what all the developments in a suit will be, and it is doubtful whether a geological expert witness can escape being a partisan witness when he is employed by one of the litigants with the obvious intent that he shall help to win the case.

Interviews With Governors of Zacatecas and Durango

By Our Representative, Alberto Terrones Benitez

I. INTERVIEW WITH THE GOVERNOR OF ZACATECAS, DR. DONATO MORENO

What is your idea of the State of Zacatecas in the way of mining?

Zacatecas is one of the richest mining States in the Republic, developed for years only in its northern part, and operations were carried to a maximum scale at a time when old treatment processes were still in use; the low silver price made possible the extraction of only high-grade ores, and as these were not found in depth, operations had to be shut-down. Lack of transportation facilities and high freight-rates also contributed to the suspension of work in the mines; but now that mining and treatment processes have evolved to a great extent, some plans have been outlined for the resumption of operations in properties where an enormous tonnage of low-grade ores is found; under this scheme the old dumps could be worked and treated. Following this general plan, operations have been already started at Fresnillo, Ojocaliente, Zacatecas, Sombrerete, Pinos, Nieves, and Mazapil. Zacatecas will thus become one of the first mining States in the Republic, as its resources are unlimited.

What steps are you disposed to take in order to encourage mining operations in the State?

First, I will grant the mining companies the maximum facilities falling within the jurisdiction of the State, and at the same time I will take up with the Federal government all matters bringing a benefit to the mining industry; this would be easy to accomplish in view of the political solidarity already existing between the States and the Federal government. Furthermore, I am discussing right now with the Geological Institute of Mexico City and with the Department of Industry and Commerce, the creation of a permanent Geological Survey Commission in the State, which will supply both the mining companies already operating and the prospective mining investors with important information at no cost; this Commission shall start working on the exploration of southern Zacatecas.

Are all the mining companies operating in the State right now?

Few of them are working now, but they are all of importance; the reason is that the country has just gone into a period of peace so indispensable for the prosperity of the Republic. I can see that some well-known mining investors in the State are feeling enthusiastic about the situation, and this government has reason to hope that within a year mining operations will reach their maximum activity.

What will be the policy of the State government in regard to taxes on mineral extraction?

This government, not only in regard to taxes on mineral extraction, but also referring to taxation in general, intends to follow a scheme of proportionate rates; in this manner the small and large producers will bear taxes in just proportion to their output, and the exploring outfits would not have to pay any taxes until they enter into a stage of production.

Is the Executive of the State disposed to facilitate the study, location, and construction of mining railroads?

Certainly I will, and furthermore necessary influence will be exercised before the Federal government for such a purpose; something about it is already discussed by the Representatives of Zacatecas in the Congress, who support our project and who are assisted by the attorneys for the State in Mexico City. Both in regard to this matter and to mining operations, this government intends to give a fair assistance to all concerned with a view to securing the general prosperity of the State and nothing else.

What is the program of the Government in order to intensify mining operations, principally in cases where the paralyzation of works is due to internal difficulties of the corporations?

If I understand this question well, I might say that referring to shut-downs caused by troubles between Capital and Labor, this government has just enacted provisions creating the Labor Department with delegations in all the mining districts of the State. This Department will conduct an intense propaganda against the nefarious activity of agitators, and at the same time will harmonize the tendencies of all parties following a program outlined by this government. So far, we have been successful, and I am sure that mining operations will not be hindered by conflicts between Labor and Capital; due to the importance of this matter it has deserved our preferred attention.

Is the State government disposed to use all its influence so that the railroad companies would grant all necessary transportation facilities to the Zacatecas miners?

Yes, and this matter is of such capital importance that it has already been taken up with the President of the Republic. Also the President-elect, Señor Alvaro Obregon, knows about it, and I presume that all effort is being made in order to supply the National railroads with necessary rolling-stock, the lack of which is causing a crisis in the country and has been a decisive factor in the increasing high cost of living.

Would the State government encourage the organization of a Mining Chamber in Zacatecas?

The organization of Chambers, either of Commerce, of Agriculture, or of Mining, is considered by us as of essential significance, provided they accomplish their end, namely, the regulation of production, of imports and exports, the supply of working capital and implements, and even the regulation of minimum salaries in all centres of production.

Would you be disposed to advise the foreign corporations through the 'Mining and Scientific Press' to resume mining operations in Zacatecas at the earliest possible date?

As already stated, this government could not be more liberal, nor could there be any better intention on the part of the Executive of the State, to facilitate all promoting business men the necessary assistance for mining operations, and the 'Mining and Scientific Press' should play an important rôle by initiating a well-intentioned propaganda with a view toward making American miners acquainted with our true situation. Should the 'Mining and Scientific Press' need any more data or statistical information in regard to mining in the State of Zacatecas, I will gladly furnish it upon application.

II. INTERVIEW WITH THE GOVERNOR OF DURANGO, GENERAL JESUS AGUSTIN CASTRO

What is your idea of the State of Durango in the way of mining?

The mineralized part of the State already under development—not counting the unexplored country—could not be worked out by 500,000 laborers working continuously during 100 years.

When taking possession of your office as Governor of the State, what policy would you follow in order to encourage mining operations?

My policy will be to facilitate the installation of as many smelters in the State as may be necessary for the miners to sell their products under non-prohibitive terms.

Have you any special program to carry out in order to intensify mining production in the State?

This question has the same answer as the former.

As the country really lacks national capital to go into the large mining ventures, are you of the opinion of calling on the foreign investors, with the understanding, of course, that all the investments made here shall be subject to the laws of this country?

I believe that an active propaganda should be started in order to evidence the unlimited mineral resources of the State of Durango practically undeveloped up to the present time. My idea is to establish a Statistical Mining Department in the State, to work either alone or in conjunction with the Industry Department of Mexico City; mining and geological explorations will be thus con-

ducted all over the State, the results to be published for the sake of information to all mining investors.

In case of calling on the foreign investor, would you be willing to use the 'Mining and Scientific Press' as a means of communication, so that those already operating in the State would resume work in the mines, and so that prospective investors should take an interest in Durango.

I think it advisable to use the paper mentioned by you as a means of communication to foreign investors, and to this effect I might as well say that the Government of the State of Durango is entirely disposed to grant all necessary protection and facilities for mining exploration and exploitation within the statutory provisions.

Is your program to encourage and support all the projects for the construction of railroads to mining camps?

The Government of the State should never hesitate to co-operate in the reorganization of all railroad schemes already existing or that may be proposed in the future.

What do you intend to do in regard to mining taxes corresponding to the State?

I have no definite plan as regards the tax on mineral extraction; but referring to taxation, in general, my idea is to try better distribution of the burden among the tax-payers, so as to be able to diminish the taxes to a just amount.

Are you disposed to encourage and support the organization of a Mining Chamber in the State?

As I understand that a Mining Chamber would have for its object to promote, safeguard, and harmonize all mining interests, it would thus co-operate with the Government, and, of course, I should support it.

Do you think advisable the establishment of a practical mining schools in the State of Durango?

As Durango is essentially a mining State, I would certainly advocate for the establishment of one technical and several practical mining schools in the State.

Have you decided to use all your influence to facilitate the railroad transportation of machinery, materials, and supplies to the mining districts?

I have decided it, and for such a purpose I have already taken this matter under my care. I have called the attention of the Federal government to the resumption of traffic between the State of Durango and the United States by way of the old International Railroad, thus getting through-communication from here to San Antonio, if necessary, without the long and tiresome detour by Saltillo and Monterrey.

Do you think that conditions in the State are such that no further delay in resuming operations is justified?

All the State of Durango is in perfect condition of safety, and therefore any delay in operating the mines is not justified.

REVIEW OF MINING

An illustration depicting a mining scene. In the foreground, a vintage open-top car is parked on a dirt road. Two men are standing near the car, one possibly in the driver's seat. The background shows a rugged, mountainous landscape with a small building and some trees.

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

PROPOSED AERO-ROUTE BETWEEN JEROME AND TONOPAH, NEVADA.—NEW CONSOLIDATION IN TOMBSTONE DISTRICT.

JEROME.—The aeroplane may become an important factor of transportation between the mining districts of Nevada and Arizona if plans now under consideration are carried out. A test flight will be made between Tono-

cross-cut from the main shaft. Shipments have netted \$100 per ton from silver-lead ore. It is planned to substitute electric power at the mine in place of the fuel-oil now in use.

TOMBSTONE.—The Mellgren group of 55 claims has been taken over by New York capitalists represented by Bisbee interests. The new company will be known as the

THE ROOSEVELT DAM. ON THE ROAD FROM GLOBE TO PHOENIX, ARIZONA

ah, Nevada, and Jerome, Arizona, in an attempt to cover the distance of 320 miles without a stop. Since the discontinuation of the Tonopah & Tidewater railroad, the quickest route by rail is from Tonopah to San Francisco, and from there into Arizona by way of Los Angeles, a trip of at least three days. The journey by air can be accomplished in less than four hours.

PATAGONIA.—An important find of rich sulphide ore is reported at the Hardshell mine, nine miles from Patagonia, near Harshaw. The new ore was opened by a

Tombstone Silver Fields Co., Inc. The same company has also taken over the Old Guard mine, on the property of which is situated a 10-stamp mill that will be used for the test-mill. The Merrimac group of seven claims is also included in the transaction, and negotiations are under way for the purchase of the Argenta group, thereby taking in practically all of the western end of the Tombstone mining district. The company plans to begin the construction of a 250-ton mill at once. Machinery for the Solstice Mining & Milling Co. has arrived and is being

set up. A compressor, hoist, and accompanying machinery, all new, are included in the equipment, which totals more than \$10,000 in value.

JEROME-VERDE.—The newly installed engine and compressor of the Verde Central are in operation, and air-drills have replaced hand-steel in driving the main tunnel. A few days should see the face of the tunnel reach the intersection of the contact, which the tunnel is following, with the main dike that cuts the country.

NOGALES.—Three leaders among the Yaqui Indians, Antonio Bacasegua, Jose Matus, and Luis Buitimea, who were at Nogales last week on their return from Magdalena, gave glowing reports of the mineral wealth in the mountainous country which the government of Mexico has given to them. Bacasegua said: "In the Sierra Bacatete, the ancient stronghold of the tribe, where we held out so long, we know of many good mineral deposits that we would like to work; and we know them to be very rich, well worth development and exploitation, with gold in abundance. Some of these mines were worked many years ago, as there are old workings and traces of habitations. We desire to be permitted to prospect and develop those mines; but we need the aid of the Government in supplying the equipment necessary for doing so. If we cannot obtain that assistance we shall turn to American capital for aid."

PHOENIX.—The Arizona Corporation Commission has denied the application of railroads operating in Arizona for permission to raise intra-state freight-rates 25%. It was alleged that costs of operating railroads had advanced in Arizona the same as elsewhere and that intra-state rates should be advanced to conform with the inter-state tariffs. What the immediate result of the commission's refusal will be is not known, but it is believed that the railroads will immediately order the printing of supplementary tariffs, embodying the increases and will apply to the courts for an injunction restraining the corporation commissioners from taking any steps to prevent the advances becoming effective. The advances, if made, will be a severe blow to the mining companies that ship ore to smelters and receive timber from mills in the northern part of the State.

BISBEE.—The Junction shaft of the Calumet & Arizona Mining Co. is being sunk 500 ft. from the 1800 to 2300-ft. level. Work has progressed approximately 225 ft., at the rate of about $3\frac{1}{2}$ ft. per day. Two compartments are being sunk to the lower level. The work of concreting the Campbell shaft of the Calumet & Arizona Mining Co. is progressing satisfactorily, and is completed from the 687-ft. level up to about the 550. The work was started from a depth of 687 ft. and it is expected that it will be completed from that point to the collar of the shaft about November 10. The shaft was originally sunk 562 ft., then raised from the 1300-ft. level and holed-through. It was then stripped to three-compartment size, to a depth of 687 ft., and concreting was started. When this section is completed, the lower part of the shaft will be stripped and concreted. The area of the completed shaft will be 170 sq. ft. Eventually this shaft will in all probability

become the main hoisting shaft of the company and should thereby reduce the cost of production.

GLOBE.—News has been received that a suit for \$500,000 for the foreclosure of a lien against the Inspiration-Miami Copper Co. has been filed in the Superior Court by attorneys representing Jacob Kleinfelder and associates. It is alleged that Kleinfelder and his associates pooled their holdings in order that the company might be formed, and that the company agreed to do a certain amount of development work, and pay them \$400,000. Plaintiffs claim that these contracts have not been fulfilled and they are therefore suing for the amount involved.

COLORADO

ACTIVITY AT CRIPPLE CREEK IS REVIVING.—BELL MINE NEAR MONTEZUMA IS OPTIONED.

CRIPPLE CREEK.—Two shifts are again employed at the Portland mine, the return of old miners and influx of new men having made the increased force possible. The production at the Portland has already shown an increase and the Battle Mountain property and Cresson mine are now the heaviest shippers of the district with the Modoc third. Development by the Dig Gold Co. on the Caledonia spur of Gold hill at the 375-ft. level is reported to have opened a strong vein of low-grade ore which is improving as the drift nears the Gold Bond vein-system. Sinking is under way at the Forest Queen mine, owned by California and Colorado people, and operated under lease by the Forest Queen Mines Co.

GEORGETOWN.—A tramway from the Snowdrift mine to the Hudson mill at Idaho Springs has been completed and shipments of low-grade dump-ore have commenced. The Silver Plume Consolidated Mining Co., operating this property, is also doing work on the Buxton mine on Hanna mountain. The Dives-Pelican dumps have been sampled and a test-run is in progress at the Wasatch-Colorado mill.

LEADVILLE.—Machinery and supplies have been hauled to the property of the Gold Leaf Mining Co. in the Tennessee Park section, where deep development is planned. A camp has been established and work will continue through the winter months. The property to be developed adjoins the Jenny June and Louis L. mines. A 'home' mining company is proposed for Leadville and a referendum will be taken by the Chamber of Commerce as to the advisability of the plan.

MONTEZUMA.—An option on the Bell mine in this district has been given to G. H. Short, a mining engineer of Salt Lake City, representing Utah operators. The Bell has been inactive for more than twenty years, but is reputed to have produced high-grade lead-silver ore. Mine records are said to show shipments of 16 cars averaging 116 oz. silver and 37% lead. A shipment of sacked ore, not figured in the average, yielded 8000 oz. of silver per ton. Mr. Short is said to have measured a good tonnage of ore blocked out with the value estimated at \$90 per ton in addition to low-grade milling ore.

ROSITA.—Ore assaying around 100 oz. silver per ton

has been opened up at a depth of 25 ft. on the Humboldt-Pocahontas vein by owners of the Stevens and West Leviathan group. Machinery will be installed. Ore assaying 75 to 100 oz. silver per ton has also been opened on the Annie recently purchased by the Fowler M. & D. Co. The Brittle Silver, an old producer, is under bond and lease to J. B. Putman, a Rosita merchant and mine-operator.

OURAY.—If weather conditions permit a power-line will be extended to the Mickey Breen property in Poughkeepsie gulch by the Loyal Mining & Milling Co., which is operating the property. A new milling-plant will be constructed next spring. The Gem City Mining & Milling Co. will continue development during the winter of its Wehawken property comprising 14 claims. A camp has been established and buildings erected for the miners. Ore outcropping at surface is reported to assay \$16 to \$50 per ton in gold, with some silver.

WESTCLIFFE.—The Plaza Flora Mining Co., operating on Bend Wert hill in the Wet Mountain Valley district, one mile north-west of Westcliffe, reports finding high-grade copper ore in its 50-ft. shaft. Samples assayed from 7 to 30% copper.

MICHIGAN

STOPE-SCRAPERS ARE BEING BUILT BY CALUMET & HECLA.—DEVELOPMENT WORK MAY BE RESUMED BY FRANKLIN.

CALUMET.—The importation of scrap-copper from abroad is seriously affecting sales of Lake copper and unless there is an unexpected turn for the better, the lull in the market is expected to continue for some time. Shipments for October have been unusually light, and there have been no outgoing cargoes of any consequence. The result is that copper is piling up and, with the exception of Calumet & Hecla, practically all producers are carrying larger surpluses than at the first of the year. Calumet's supply is estimated at more than 22,250,000 lb., including 13,000,000 on the docks of the old Union Smelting plant. The Stanton mines—Mohawk and Wolverine—are among the few that are caught up on production and these properties would produce more copper if men were available. The Copper Range mines have about the same amount of metal on hand as six months ago, while Quincy makes only occasional shipments.

According to present indications the mines will not suffer from a shortage of labor this winter, for large groups of former employees are returning from the automobile factories. The Calumet & Hecla mines are gaining about 25 men per week, with the majority of the new employees being given places in the conglomerate department. Isle Royale is well supplied with labor, maintaining a force sufficient to keep its own milling plant operating to capacity, and Ahmeek's force is as large as conditions warrant. Notwithstanding the fact that production is barely more than 50% of normal, there is no unemployment in the Lake region. Some of the smaller mines are idle, but whenever an underground man seeks a job he has no difficulty in finding one. It required years to build up organizations to the standard of effi-

ciency that ruled in the Lake district and every effort is being made to keep the forces as nearly intact as possible.

Calumet & Hecla has begun to make stope-scrapers in its shops and by spring it will have a fairly large supply for use in its own shafts. The subsidiaries in all likelihood will be supplied as soon as possible, but it may take more than a year before the scrapers are in general use.

MAP OF CENTRAL COLORADO

A scraper, operated by two men, can perform the same work that six to eight do by hand in the same length of time. Not only will this device help to reduce costs, but it no longer will be necessary to seek trammers as in the past, once the scrapers are available in sufficient numbers. Trimming is the hardest work in a mine and the introduction of these machines will do away with much of the drudgery. When labor has been scarce the first department to suffer has been trimming and a shortage in this particular immediately affects production.

Calumet & Hecla's haulage-level is proceeding southward slowly, with the drift breasted about 1000 ft. south of the Hecla No. 7 shaft. The terminal still is close to 2000 ft. distant, so it probably will be the end of 1921 before the project is complete. The tunnel is 12 ft. wide and at the end of each 700-ft. section drilling is stopped to permit the application of a coat of gunite on the walls and top. The haulage-way will connect all of the Calumet & Hecla and Tamarack conglomerate shafts. It is 8100 ft. from the surface and will be $1\frac{1}{2}$ miles long. No. 12 shaft, C. & H. will be the supply and pumping-shaft, while the Red Jacket will be used for hoisting. All of the surface equipment of the other shafts will be dispensed with, once the new haulage-way is in operation. The project will require the construction of a sump with a capacity of 3,000,000 gal. and the installation of more powerful pumps. To operate these pumps two large high-pressure steam turbines will be installed at the mills, increasing the capacity of the power-plant to a point where it can meet any emergency.

An announcement is expected shortly as to the future course of Franklin. The company may determine to resume development at once so that it will be able to produce on a quantity basis more quickly than if additional opening work was deferred. Franklin's first operations, when production is resumed, doubtless will be on the 39th level, north, where splendid disclosures were made on the Pewabic lode. For a distance of 600 ft. ground that should yield 25 lb., refined, has been proved and it is believed that the same mineralization will extend up to the 30th level. Since development work ceased some months ago only the pumps have run.

The Copper Range mines report a slight decrease in output during the past month, but the yield holds up well, with Champion averaging 45 lb., refined, Baltic varying from 30 to 35, and Trimountain, 27. Mass enters into this, however, particularly at Champion, though the shipments of native copper are not as large as when the mine was operating at the peak. Development work at Champion practically has stopped and few new openings are being made at Baltic. On the other hand, Trimountain is in the midst of extensive development of the bottom of the mine.

There is a likelihood that one of the first tests with flotation on amygdaloid 'rock' will be made by the Copper Range company. If an additional pound of copper per ton can be recovered by means of this process it will increase the output, based on the average production for 10 years, by 1,000,000 lb. per year. If Copper Range can successfully and profitably apply flotation, Mohawk likewise could increase its yield, though the latter plans to direct its first efforts toward reducing losses by finer grinding.

NEVADA

NEVADA SECTION OF A. I. M. & M. E. MEETS AT TONOPAH.—LESSEES AT POCHE DISCONTINUE ON ACCOUNT OF FREIGHT-RATES.

DIVIDE.—The cross-cuts on the 800 and 1000-ft. levels

of the Tonopah Divide have entered the vein and drifting has been started. That on the 800-ft. level entered the vein at 180 ft. from the shaft and that on the 1000 entered it at 200 ft. from the shaft, the latter having been driven farther south-east. The Victory has cut the vein at 500 ft. and ore assaying \$35 to \$40 for a width of 6 ft., the width of the vein, has been found. A drift is now being driven. The vein was entered 110 ft. from the winze from the 200-ft. level. The south-east drift on the 400-ft. level of the East Divide, being driven in a vein 30 to 40 ft. wide, continues to expose narrow seams of ore. The vein is narrowing, giving the management hope that a good width of ore that can be shipped will be found. This drift is being driven toward the extension of the vein recently found in the Gold Zone and the so-called Julian vein of the Tonopah Divide. Ore $3\frac{1}{2}$ ft. wide and assaying \$15 to \$20 has been found in the south-east drift on the 400-ft. level of the Alto. This drift also is being driven toward the extension of the veins striking into the Alto from the Gold Zone and Tonopah Divide. The Kernick, at a depth of 900 ft., has started work to prospect a large territory in the western part of the district, including the Hasbrouck, Western, Revert, and Annex. The Brouger is sinking from the 500-ft. level a winze that, at 1000 ft., will be connected with the Tonopah Divide workings. The Gold Zone has started shipping from the vein found recently on the 700-ft. level and it is estimated that 1000 tons is available. The shoot is 45 ft. long. It is the frequently expressed opinion of engineers in charge of work in nearby ground that the Zone will have to sink farther before the best results can be obtained near the Tonopah Divide line.

TOLICHA.—It is reported that the deal for the sale of the Landmark group has fallen through, the holders of the option having relinquished it for an unknown reason. W. J. Loring has denied that he is connected with any deal involving the claims.

LEADVILLE.—The 50-ton concentrator of the Leadville Mines Co. has been started and it is expected that within two weeks it will be operating at capacity. There is estimated to be blocked out in the mine 5000 tons of ore containing 30 oz. silver and 5% lead. The earning capacity over all mine and mill expense will be \$10,000 monthly, according to A. A. Codd, general manager, who says the production of the plant will be 150 tons of \$200 material monthly. The vein, 3 to 4 ft. wide, is in a fissure in limestone. The mine is worked through a 1500-ft. tunnel, from which a 300-ft. winze has been sunk. Most of the ore is in workings from the bottom of the winze, 500 ft. from the surface. The Grandma shaft is now 870 ft. deep. Since sinking was resumed it has passed through a tongue of alaskite, then shale, and it is now in alaskite, a reversal of the order in which these formations are usually found in the district. The flow of water is heavy and this has retarded sinking.

VIRGINIA CITY.—During the last week 67 tons of ore of a gross value of \$35,000 was mined in the drift from the bonanza winze from the 2150-ft. level of the Consolidated Virginia. This drift is 80 ft. long. The east

drift on the 2250-ft. level has been re-opened and a raise is to be driven from it to the winze from the 2150. Ore also is being broken on the 1950 and 2050-ft. levels. During the week 341 tons of ore of a gross value of \$15,000 was treated at the Mexican mill.

TONOPAH.—The annual meeting of the Nevada section of the American Institute of Mining and Metallurgical Engineers was held in Tonopah on October 26 and 27, with 40 present. The following officers were elected: John G. Kirchen of Tonopah, chairman; J. C. Jones, professor of geology, University of Nevada, vice-chairman; H. M. Rives of Reno, secretary-treasurer. The executive committee is composed of John G. Kirchen.

shipments to Salt Lake valley smelters. Ore having a value of \$20 per ton now takes a rate of \$7, as compared with the former rate of \$4.50 per ton. This is a heavy burden on the industry, particularly in view of the declining market for the metals produced. During the week ending October 23, the Prince Consolidated shipped 1925 tons; Virginia-Louise, 505; Combined Metals, 150; Bristol Silver Mines, 90; Columbia Trust, 40; making a grand total of 2710 tons. Negotiations are pending for the sale of the Silver King mine, 38 miles north-west of here, by Vernon Jeffcott and C. M. West of Pioche. The property comprises four claims, and in 1902 some bonanza silver ore was found. Several tons of ore running

GLORY-HOLE AT COMBINATION SHAFT, GOLDFIELD, NEVADA

J. C. Jones, R. A. Hardy, Virginia City; W. S. Larsh, Ruth; F. Dean Bradley, Goldfield; Governor Emmet D. Boyle; J. L. Dynan, Tonopah; Alex Wise, Virginia City; W. H. Blackburn, Tonopah. The following papers were read: 'Surface Plant at Victor Shaft, Tonopah Extension Mine', J. P. Hart; 'Operating Conditions at Tonopah Extension', John L. Dynan; 'Mine Pumping in Tonopah District', Homer L. Williams; 'Crushing and Agitating Practice at Tonopah Extension Mill', H. A. Burk; 'Precipitation and Refining of Gold Concentrates at West End Mill', Fred Ninnis and Walter Anderson; 'Tonopah Extension Assay Office', George L. Christian; 'Mine Accounting', F. Dean Bradley.

PIOCHE.—A number of lessees in this vicinity have ceased operations, as a result of the increase in freight-rates on ore-shipments and incoming supplies. It is estimated that the operators here paid an additional \$7000 during September by reason of the higher rates on ore

as high as 10,000 oz. per ton was shipped, which resulted in a rush to the district, the ground being staked for miles around. It is stated that 400 tons of material has been sorted from the old dumps, which averages 11.5 oz. silver and 4.3% lead. In the early days, when the property was 150 miles from a railway, a 50-ton smelter was built. The Salt Lake Route now passes within 23 miles of the property and there is a good road connecting the mine with Jackrabbit station.

UTAH

SMELTING COMPANIES ARE SUED BY RAILROADS.—REGULAR SHIPMENTS ARE BEING MADE FROM AMERICAN FORK CANYON.

SALT LAKE CITY.—The University of Utah will give extension-courses in mining, milling, smelting, and Americanization in the various mining districts of the

State, according to F. W. Reynolds, in charge of the extension division. The mining and metallurgical courses will be under the direction of Robert S. Lewis, professor of mining, while the Americanization work will be under the supervision of A. M. Thurman. During the week ending October 23, the Utah Ore Sampling Co. at Murray released 68 cars of ore from Utah mines; 8 from Nevada; 5 from California; and 2 from Idaho. At the Tintic plant of the company, 34 cars from Utah mines were released. The Oregon Short Line Railroad Co., acting on behalf of itself, the Denver & Rio Grande, and Los Angeles & Salt Lake railroads filed suit on October 26 in the U. S. District Court against the American Smelting & Refining Co., seeking to collect \$23,830, with interest from date of filing. The money is alleged to be due to the railroad companies for the building of a switching system at the Murray plant of the company, seven miles south of this city, and for the handling of railway cars used in making shipments. The Denver & Rio Grande and Los Angeles & Salt Lake companies participated in the expense, and conveyed their claims to the Oregon Short Line for collection. On October 28 the same companies also filed suit against the United States Smelting Co., for \$23,006, alleged to be due for switching performed at the Midvale smelter of the company from November 1916 to December 31, 1917.

OPHIR.—At the property of the Ophir Silver Mines Co. the adit is now in a distance of 110 ft., and it is expected that within an additional 50 ft. the Buckhorn vein, said to be the productive lode in the Ophir Hill Consolidated mine, will be cut. Drifting to the north and south will follow. At about 200 ft. south a promising east-west vein, developed near the surface by an inclined shaft, should be cut. In this tunnel three feet of ore was opened containing 2 to 4% copper and from 50 to 100 oz. silver per ton. This vein had to be abandoned in the upper workings because of caving ground.

AMERICAN FORK.—An examination of the Pittsburgh mine in American Fork canyon has recently been made, and it is reported that the property will be taken over by Eastern interests. The mine is owned by the Alexander T. Tarbett estate of Salt Lake City. In 1916 Mr. Tarbett was actively engaged in deep development of the property, which is situated on the divide between American Fork and Little Cottonwood canyons. In the early days, the mine was one of the largest producers of silver-lead ore in this district. It is stated that there is about 16,000 tons of milling ore in sight. Two mines in the canyon are making regular shipments. The Silver Dipper property, under lease to George Hemphill and associates, is making steady shipments of silver-lead ore. Shipments of sulphide ore containing lead-silver-gold are being made by the Belorophan property, of which Carl Ferlin is manager. The Globe Consolidated property has been closed for the winter, according to John Cleghorn, president. Shipping ore has been found in several places, and if it were not for the lateness of the season, shipments could be made. There is more than a foot of snow, which is unusual for October.

PARK CITY.—Exploration of the O'Brien vein-system by the Silver King Coalition and Three Kings Consolidated Mining companies is giving important disclosures. Work already done in the Coalition property proves that the O'Brien chanel is a third large ore-zone in the district, and engineers predict that it will equal the Silver King zone as a producer of rich ore. The O'Brien system is a series of fissures and faults which strike north-east approximately 1200 ft. north-west of the Silver King zone. The Park City limestone, which is regarded as the formation in which the best bedded ore deposits have been found, is traversed by the system of fractures. The fractured zone is about 800 ft. wide. In the Three Kings property, a cross-cut was driven from the shaft a distance of 1000 ft. to the south-east, on the 500-ft. level, to cut the strata that dip north-west. A zone of intense fracturing was developed by this work. Some of the ore assays 100 oz. silver and 60% lead. The Three Kings property owns 156 acres of patented ground and is believed to have several thousand feet on the strike of the O'Brien channel.

Conditions at the Naildriver mine are promising, according to J. D. Fisher, superintendent. Recently a vein was cut on the 500-ft. level, which is thought to be a continuation of the orebody opened on the 700 and 900-ft. levels. Steady shipments are now being made. During the week ending October 23, the Silver King Coalition Mines shipped 646 tons of ore; Ontario, 497; Judge, 289; Daly-West, 168; Naildriver, 60; Keystone, 55; and New Quincy, 3; making a total of 1718 tons. The machinery for the new milling plant at the Glenallen property is being placed, according to J. B. Allen, manager. Inasmuch as it has to be hauled from Heber over poor roads, there has been more or less delay, but it is expected that the plant will be ready for operation by the first of the year. It is stated that there is a large tonnage of milling ore developed in the mine merely waiting the completion of the mill.

EUREKA.—Shipments of ore from this district during the week ending October 23 totaled 169 cars, an increase of 46 cars over the previous week's shipments. The Chief Consolidated shipped 41 cars; Tintic Standard, 34; Mammoth, 23; Dragon, 15; Iron Blossom, 12; Eagle & Blue Bell, 8; Centennial-Eureka, 6; Iron King, 6; Grand Central, 6; Victoria, 4; Swansea, 4; Bullion-Beck, 3; Gemini, 3; Gold Chain, 2; Eureka Hill and Yankee, each 1. A contract has been signed between the Dragon Consolidated Mining Co. and the United States Smelting Co., whereby the former will ship about 100 tons of iron ore per day to the Midvale plant of the smelting company. The north end of the Dragon property is under lease to the Tintic Milling Co. and approximately 50 tons per day of mill-grade ore is being extracted. The Tintic Delaware Mining Co. has filed an amendment with the county clerk of Utah, seeking permission to make the capital assessable. For some time past, this property has been idle, but recently a decision was reached to resume operations and for this purpose it is necessary to levy an assessment.

BRITISH COLUMBIA

PRODUCTION AT COPPER MOUNTAIN COMMENCES.

PRINCETON.—After a long series of delays, the Canada Copper Corporation started actual mining operations at its Copper Mountain property on October 19, and on that day the first trainload of ore went to the mill, at Allenby, four miles away. Numerous strikes have delayed operations at mine, mill, and railway; and other difficulties have appeared. The undertaking represents an investment of \$7,000,000, which, owing to the many delays and the rise in cost of labor and supplies is \$500,000 more than the original estimate. At the present time the company has 300 men on the payroll, this number to be increased gradually to 500. Before the end of the year it is hoped to bring the output of the mine up to 2000 tons per day which is the present capacity of the mill. The company has developed 12,000,000 tons of ore, and this, it is believed, can be mined and milled at a low figure. The concentrate will be sintered and smelted at Trail. Edwin T. Hodge, general manager for the Liberator Mining Co., which owns the Emancipation mine, near Hope, states that the development tunnel is being driven at the rate of 10 ft. per day and that the upper tunnel has penetrated five ore-shoots and has entered the sixth. During the last two months a compressor and a power-plant have been erected and an assay-office has been built. A quantity of mill-ore has been taken out during the course of development.

ANYOX.—The Granby Consolidated M. S. & P. Co. produced 2,239,174 lb. of copper during September, against 2,439,200 lb. in August. The company made a net profit of \$443,586 during the first half of the present year; from this, however, taxes and interest on bond issue have not been deducted. The profit for the last half of last year was \$599,386, and taxes and interest amounted to \$539,487, leaving only \$49,899. The smelter town expressed its wishes emphatically at the plebiscite, on October 20, giving a vote of practically 10 to 1 against prohibition.

PRINCE RUPERT.—The net earnings of the Belmont-Surf Inlet Mines, Ltd., a subsidiary of the Tonopah-Belmont Development Co., for the quarter ended June 30, 1920, amounted to \$77,535. Last year this company did 5550 ft. of development, and this year it has kept development work well ahead. The company produces a high-grade gold-silver-copper concentrate, which is shipped to the Tacoma smelter.

STEWART.—S. G. Benson, an operator in the Portland Canal district, refers optimistically to the Blue Bird and Nest Egg claims on the Salmon river. Several veins have been uncovered from which samples have been taken that give good assays. Mr. Benson and his partner have been prospecting this particular country for years, but it was not until last year that they found anything worth while, due to the fact that a glacier, which has been receding about 200 ft. each year, formerly covered the outcrops. It is the intention to begin tunneling next season. On the Lucky Boy group in the same locality a vein has been found about 60 ft. wide, the average value of the ore being

estimated at \$100 per ton. It is stated that the galena from this property is the cleanest seen in the country so far, there being no zinc. Considerable development has been done but next year permanent camps will be established. This property is situated between the Premier mine and the town of Stewart. Much is expected, too, of the New York group. The results of recent work is reported to have been satisfactory. Owners of the White Mouse, also, are understood to be planning the erection of a mine plant.

ALICE ARM.—The Esperanza group of mineral claims has been taken over by a syndicate of Vancouver businessmen. The consideration is said to have been \$75,000 which nets the owner, Petro Salina, a comfortable profit which will be appreciated when it is stated that he acquired the property some years ago at a sheriff's sale for \$200. Recent development work has been encouraging,

KIRKLAND LAKE DISTRICT, ONTARIO

with a considerable body of high-grade silver ore uncovered.

PRINCE GEORGE.—There is a possibility that one or more of the same type of giant gold-dredges that have been operating in the State of California will be constructed for digging the gold-bearing gravels of the Fraser river and of the creeks and gulches of the Cariboo district. A party of operators from the United States, one of whom represents the Yuba Manufacturing Co., of Marysville, California, has been visiting Prince George for the purpose of investigating conditions and forming an estimate of the prospects of success attending the venture. Years ago, as an aftermath of the Cariboo gold excitement, several small dredges were built on the Fraser river and elsewhere. The remains of these still may be seen in the river and on the banks just below the town of Quesnelle. There is a dredge on the Quesnelle river and one was taken up-stream beyond Fort George to the Little Smoky river, where it lies a derelict today.

VICTORIA.—With reference to the policy of the Provincial government of assisting in the exploration and development of such mining properties as seem to merit the expenditure, where the owners are unable to do their own financing, William Sloan, Minister of Mines, has made an interesting statement concerning the past year's work. He says that diamond-drilling and other development has been in progress for some months on the Snow-storm group in the Highland valley and that drilling has been undertaken by the Government in the Franklin camp, the results in both cases being satisfactory. R. W.

Thomson, engineer, who is in charge at the Snowstorm, says that it is expected that it will take another year to complete the work in hand. A large amount of ore has already been developed. The minister says in conclusion: "On work of this character the Government has a bonus-charge against the property equal to the cost of the work, that is to say, for every dollar spent in development the property will owe the Government two dollars. Although it is not expected that all diamond-drilling operations will prove remunerative, the policy of the department is to place this drilling and development of mineral claims, as far as possible, on a profitable basis."

ONTARIO

FLAT WAGE OF \$5.25 ANNOUNCED BY TEMISKAMING MINE OPERATORS.—MORE MINERS REQUIRED AT PORCUPINE.

COBALT.—The Temiskaming Mine Managers' Association has notified the Central Council of workmen in the silver mines in the district that after November 1 a flat wage will be paid instead of the former base wage plus a bonus determined by the price of silver. Formerly machine-runners were paid \$4 daily, when silver was under 80c. per ounce, with a bonus of 25c. when the price was 80c. and an additional 25c. for each ten points above 80c. per ounce. Accordingly the bonus amounted to \$1.50 per day when the price of silver rose to over \$1.30 early this year. On the other hand, when the decline in quotations carried the price down, the companies announced that they would continue the bonus of \$1.25 until November 1. The schedule now announced gives to machine-runners a flat wage of \$5.25 per day, the highest ever paid in Cobalt. Low water on the Montreal river has caused a serious shortage of power, causing the mines to curtail operations to some extent. Arrangements have been made to work certain of the mines alternately pending rainfall. On November 1 the Coniagas will disburse a dividend of 2½%, amounting to \$100,000. This makes a total of \$500,000 paid this year, and a grand total to date from this company of \$10,040,000.

The Keeley Mines in South Lorrain has completed the erection of a 20-stamp mill. The plant is being tried out this week. The equipment was purchased early last spring from the Coniagas Mines, this being a part of the machinery on the Trethewey mine the property and plant of which was purchased for \$100,000 by the Coniagas early this year. The development work on the Keeley has been favorable during recent months. A shipment of 11 tons of high-grade ore has been made from the Castle property at Gowganda. The brokerage firm of F. C. Sutherland & Co., of Toronto, has acquired an option on the tailing from the Penn-Canadian mill and hopes to make arrangements for the recovery of the contained metal.

At the Lumsden property of the Camburn Mining Co. the Croft vein has been opened up more than 50 ft. with high-grade silver veins appearing at intervals. A winze is being put down on the Horseshoe vein from the 300-ft. level to the diabase-Keewatin contact estimated to be 175

ft. below. Several other properties are being prospected in the vicinity of the Lumsden, all of which are sinking to reach the contact, influenced by the success of the Beaver and Temiskaming at that depth.

PORCUPINE.—The need for additional mine workers at this camp is receiving the attention of the Provincial government. H. C. Hudson, general superintendent of the Employment Service branch, has made an official visit to the mining districts of Northern Ontario. The labor requirements of Porcupine, Kirkland Lake, and Cobalt are estimated at 2000 men. By far the most serious shortage is at Porcupine, where the Hollinger Consolidated is prepared to take on 800 additional men, while the Dome, McIntyre, Porcupine Crown, and Vipond-North Thompson are anxious to increase their working forces. The Dome is endeavoring to secure labor from England. Mine operators are hopeful now that the urgency of the situation has been made the subject of an official enquiry that the Ontario government may take some action for their relief.

KIRKLAND LAKE.—The Kirkland Lake Proprietary, Ltd., has completed the taking over of the assets of the English Tough Oakes, the old Kirkland Lake company, the English Aladdin-Cobalt, and the Sudbury Syndicate. The new company is also arranging to acquire the assets of the Ontario-Tough Oakes Gold Mines, the Burnside, and the Sylvanite.

GOWGANDA.—A vein intersected in a cross-cut at the 85-ft. level of the Castle property of the Trethewey shows a width of six inches of high-grade silver ore, and wall-rock heavily impregnated with silver. Another important find has been made at the Miller Lake-O'Brien, the vein several inches in width, carrying heavy leaf silver. A narrow vein of this character of ore can be worked with a good margin of profit.

TORONTO.—Reports were recently received by the Imperial Oil Co. of an important strike in the well at Fort Norman on the Mackenzie river, near the Arctic circle, where the flow was stated to be at the rate of from 1000 to 1500 barrels per day. C. O. Stillman, president of the Imperial company, states that he has received confirmation of the news. The 'strike' was made August 25 at a depth of 783 ft., oil flowing out of the 6-in. pipe for 30 minutes before the well was capped. Any estimate, however, as to the amount of oil this well could produce is only a guess as there was no tankage available, and an accurate test could not be made. While he considered it of scientific value, from a commercial point of view it is not of immediate value, as it would probably be years before it could be made available in quantities for the use of the Canadian market on account of its remoteness. The well is situated 45 miles below Fort Norman, 900 miles from the nearest sailing point of a river boat, 1200 miles from the nearest railroad, and 1500 miles north of Edmonton, the nearest city by the present route. The only means of access is down the northern rivers, which will only float boats of shallow draught and several rapids necessitate the unloading and transporting of cargoes overland and loading on barges again. The cost of laying a pipe-line would be approximately \$50,000,000.

THE MINING SUMMARY

ARIZONA

Bisbee.—It is reported that the new sulphide orebody on the 600-ft. level of the Boras Leasing Co.'s mine is now 60 ft. long and 30 ft. wide averaging about 7% copper. The fourth monthly disbursement of 10c. per share was recently made. Production is being maintained at approximately 1250 tons of 8% copper ore per month.

Gunsight.—Seven men are at work constructing foundations for a cyanide plant that is to be erected at the New Gunsight mine.

Ray.—The new mill of the White Metals Co., erected by Kennard and Pierce, engineers of Los Angeles, is completed. The mill is a 50-ton flotation plant designed to treat the ore from the Pioneer mine. J. C. Devine is manager.

Oatman.—The east drift on the 400-ft. level of the Aztec vein of the Tom Reed has now penetrated the orebody about 100 ft. and is nearly 300 ft. west of the United American end line. It is reported that ore opened in the face of the tunnel contains \$70 in gold per ton, and the vein is 3 to 5 ft. wide. The United American is cross-cutting 175 ft. above the level of the Tom Reed and should reach the same vein in 10 to 15 days.—The Telluride Mining Co. is now drifting on the vein on the 516-ft. level. It is reported that on this level a well defined vein has been opened which is about 25 ft. wide. Fifteen feet of this vein is quartz, one stringer of which assays \$76 per ton in gold.

CALIFORNIA

Amador County.—An important strike has been made in the Plymouth Consolidated. On the 3050-ft. level a new ore-shoot has been cut at a point 100 ft. north of the main cross-cut. So far, for 140 ft. of drift, the ore averages an ounce of gold per ton for an average width of 10 feet.

Grass Valley.—The winze from the 400-ft. level of the Alcalde mine has been in milling ore all the way, according to a late report from the property, with considerable high-grade quartz in evidence. Ore containing free gold in a vein three feet thick has been found. As soon as the winze has gained the desired depth, cross-cuts and drifts will be driven out to develop the orebody. An electric hoist has been received and will soon be installed in the winze. The mill is being overhauled. Mining operations are rapidly becoming normal throughout the Grass Valley district as a result of withdrawal of restrictions regulating the use of electric power. The Empire company has resumed full operations at the Pennsylvania and Empire properties, and the Empire mill is running at capacity. The Idaho-Maryland is speeding up the work of unwatering its workings, and activity has been increased at the North Star, Boundary, Allison Ranch, and other properties. The shortage of labor is less acute and the general situation is encouraging.

Plumas County.—Persistent reports are current that the Plumas-Eureka gold mine, near Johnsville, has passed to the control of the Guggenheim interests. The property is situated near the Plumas copper-belt, but for many years was one of the greatest of Californian gold producers.

Work is being pushed rapidly at the property of the Rein-miller Copper Mining Co., situated in the Lights Canyon district. The company owns by location, bond, and option, ap-

proximately 50 claims, joining the Engels mine on the north.

The main development work done so far consists of one shaft 65 ft. deep, two tunnels approximately 70 ft. long, and five open-cuts. All of this work has developed copper ore containing some gold and silver.

Shasta County.—The Mountain Copper Co. has increased operations at the Hornet mine and the new crushing plant is handling 400 to 500 tons of ore daily. The plant is equipped with two sets of rolls and has a rated capacity of 600 tons per day. The ore contains pyrite and the product is shipped to San Francisco for conversion into chemicals and fertilizing agents. The company is erecting additional cottages near the mine for its employees. A large reserve of copper ore has been blocked out in the Hornet and Iron Mountain properties, but this product will not be mined until the market for copper improves.

Siskiyou County.—The Davis Consolidated, now that the Lagrange mine in Trinity county is shut-down, is the largest hydraulic mine in the State. Three giants are kept going and 16 men are employed. Five thousand inches of water is diverted from Indian creek and Girder creek through ditches that unite and deliver water at the giants through 32-in. pipe. Reeves Davis of San Francisco owns the mine.—The old Washington mine near French Gulch is being operated by George E. C. Rousseau of San Francisco. Eight men are employed. This is one of the oldest mines in the French Gulch district.

Trinity County.—Operations have been resumed at the Bonanza King gold property, near Trinity Center, after an idleness of three months because of water shortage. The property is one of the largest producers in the county, and was formerly held by the Treadwell interests of Alaska and San Francisco. Scarcity of skilled miners is hampering activities.

IDAHO

Coeur d'Alene.—Better ore than found heretofore in the Hecla mine is reported on the 2000-ft. level. On this level the company is mining five feet of clean galena, without a trace of zinc. Besides this in the same shoot there is from five to six feet of good milling ore. This shoot has persisted for a long distance and on the 1600-ft. level proved 1800 ft. long.—The Bullion Mining Co. is proceeding steadily with development. The main tunnel has followed ore for 300 ft. This is at a point in the tunnel 4000 ft. from its portal and at a depth of 1000 ft. The orebody is wider than the tunnel. The ore contains \$50 to \$60 in copper and \$7 to \$8 in silver per ton. The tunnel has passed a point vertically under the No. 2 tunnel. The quantity of ore disclosed warrants the building of a concentrating mill.—The blower to be used in the new zinc unit of the Nabob Consolidated plant has reached the property. It is expected to increase the grade of zinc to 42%. Ore-hauling has been in progress between the mill and the railroad for some time.—A contract has been let for the performance of several hundred feet of tunnel work in the Slavonian mine owning three claims east of the Last Chance and adjoining the Bunker Hill & Sullivan on the north. The work, which will advance the tunnel into promising ground, will be done with machine drills.

MONTANA

Butte.—It is declared that the market for zinc must rise to 9c. per pound before independent producers can operate at a profit. This estimate takes into consideration the amount of silver found in zinc ores of the Butte district. With increased freight rates, together with the greater cost of smelting, mining, and supplies, a ton of zinc concentrate is costing \$30 more than the 10-year pre-war average, while only \$4 more per ton is realized, due to the enhanced price of silver. An additional \$16 per ton of concentrate can be included on account of increased price of zinc which theoretically leaves the producer with \$10 less profit on each ton of zinc concentrate produced, than hitherto. The Anaconda company is making some profit on its zinc operations and there have been calls for increased deliveries of concentrate made to independent producers of the Butte district, but the market is so variable that from one month to the other zinc producers have no definite idea as to the outlook. Anaconda's operations on custom concentrate are more profitable than those on its own ores, which carry about 30% zinc as compared with 50% or more in the custom product. Butte & Superior had been shipping to Anaconda, but the bulk of its concentrate is now going to the plants of the American Metal Co. The Timber Butte Co. is shipping considerable to Anaconda. Anaconda is producing from 6000 to 7000 tons of zinc concentrate monthly from its own ores. The sentiment prevails here that the Joplin and Miami producers are smothering the spelter market through a disinclination to reduce their output sufficiently to stiffen quotations, and that if such a step were taken by those producers a betterment of spelter quotations would be had within a comparatively brief period.

UTAH

Salt Lake City.—A complete and authoritative map of the Tintic mining district, showing the property lines of all of the mining companies in the district, with groups of unpatented as well as patented claims, has been prepared by J. B. Ireland, whose office is in the Dooly block. The map is printed on sheets 17 by 28 in. A feature is the revision of the boundaries of the groups in the East Tintic section where the Tintic Standard property is situated.

WASHINGTON

Spokane.—A brief on blue-sky legislation has been prepared by the mining bureau of the Spokane Chamber of Commerce, of which F. W. Smith, smelter director for the Bunker Hill & Sullivan Mining & Concentrating Co., is chairman. The brief analyzes the Frawley bill and opposes its endorsement by the Chamber of Commerce as requested by the Better Business Bureau, an adjunct of the Spokane Advertising Club. It will be considered at a joint meeting of the committees and if adopted at that time will go before the trustees of the Chamber for consideration. While opposing the State blue-sky legislation, the brief advocates the enactment of a Federal law providing that full information shall be filed in the originating State of the corporation and at Washington, D. C. Also, it favors the automatic opening of all States to a promotion when it has been passed on by Federal authorities at Washington.—It is reported that the Anaconda Copper Mining Co. may establish a mining and metallurgical department in this State. It seeks a source of aluminum and to this end has been engaged in the investigation of clay deposits near Mica, a few miles south-east of here.

HOOVER TO ADDRESS MEETING OF SAN FRANCISCO SECTION, A. I. M. & M. E.

Herbert C. Hoover, President of the American Institute of Mining and Metallurgical Engineers, will address the members of the local section at a meeting to be held at the Engineers Club on Tuesday evening, November 9. Dinner will be served promptly at 6 p.m.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Henry F. Collins is at La Espina, in Spain.

L. D. Ricketts is in New York, convalescing from an operation.

G. Allen Crane has opened an office as consulting mining engineer at Vancouver, B. C.

F. Lynwood Garrison is at Miami, Oklahoma, and will remain there until Christmas.

Herbert Hoover was at Salt Lake City last week on his way from New York to his home at Palo Alto.

R. L. Chase will be engaged on oil-shale examination work in western Colorado during the month of November.

John M. Hayes, treasurer for the Utah Copper Co. at Salt Lake City, has resigned, and will become a resident of Los Angeles.

L. R. Perry, of Forest City, Iowa, president of the Iowa Copper Co. at Park City, Utah, has been visiting the company's property.

Fred S. Stephen, president of the Dundee Arizona Copper Co., and **George Scott**, both of Dundee, Scotland, are visiting Jerome, Arizona.

Jack Flynn, formerly superintendent for the Jerome Copper Co., has been appointed general superintendent for the El Oro Railroad & Mining Co., at El Oro, Mexico.

Pierce & Skogmark, Inc., metallurgical and chemical engineers, formerly at 35 Nassau street, New York, are now associated in the practice of engineering work with **L. L. Summers & Co.**, at 140 Nassau street.

Olaf P. Jenkins has returned to Pullman, Washington, as professor of economic geology in the State College of Washington, having spent the last year with the Sinclair Exploration Co. as chief geologist in Alabama.

Obituary

Rutherford B. Sumner, mechanical superintendent of the International Smelting & Refining Co. at Tooele, Utah, died on October 25, of pneumonia. He was born at Northfield, Minnesota, 42 years ago, and after graduating from the University of Michigan, came West, accepting a position with the City Engineer's office at Salt Lake City. He became associated with the Tooele smelter in 1909 as chief draftsman, holding that position until 1917, when he was promoted to mechanical superintendent. He is survived by his wife, mother, and several brothers and sisters. He leaves a large circle of friends and business associates who mourn his untimely death.

Alexander J. McCone, president of the Fulton Engine Works, died in Los Angeles on October 27. He was born at Placerville, California, in 1860. He was educated at Santa Clara College and later took a business course at Heald's Business College. He became manager for his father at the Fulton Foundry in Virginia City, where he remained from 1876 to 1900; he founded the Fulton Engine Works of Los Angeles in 1890, moving the shop from Tucson, Arizona; in 1900 he established the firm of Harron, Rickard & McCone, which took over the business of Parke & Lacy, in San Francisco. He was interested in mining in Nevada, California, and Arizona, and a pioneer in the cyanide processes in Nevada, working the tailings from the Comstock mines. He moved the Fulton Foundry from Virginia City to Reno and established the Nevada Engineering Works in 1900, which built machinery for mines at Goldfield and Tonopah. He leaves his widow and four children.

THE METAL MARKET

METAL PRICES

San Francisco, November 1

Aluminum dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	16.50
Lead, pig, cents per pound.....	7.50-8.50
Platinum, pure, per ounce.....	\$95
Platinum, 10% Iridium, per ounce.....	\$135
Quicksilver, per flask of 75 lb.....	\$60
Spelter, cents per pound.....	9.50
Zinc dust, cents per pound.....	12.50-13.00

EASTERN METAL MARKET

(By wire from New York)

November 1.—Copper is inactive but easy. Lead is dull and lower. Zinc is quiet and steadier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange.

ZINC PRODUCTION

At present the world's chief source of zinc is the United States, which gained supremacy in the zinc industry when the War eliminated Germany and Belgium from this field, says "Commerce Monthly". The United States had little export trade in this metal until the War forced foreign consumers to turn to American markets, but its trade is now in excess of that of any other nation and probably will remain so because of the continuing incapacity of the former producing countries to supply the market. The United States exported 109,232 tons of zinc in the first eight months of this year, or nearly ten times the annual amount exported before the War.

Belgium and Germany used to supply most of the international demand, but these countries are not now able to produce zinc to compete with the American product. In 1913 Belgium exported 194,513 tons of spelter, or more than nine times as much as did the United States. Although many of the zinc plants escaped destruction during the occupation of Belgium, others were completely dismantled. There has been a loss, moreover, through the disorganization of the skilled laboring force as a consequence of the War. At the same time there is a serious shortage of fuel and of zinc ore.

Unlike the Belgians, the Germans smelted principally from domestic ore. Present fuel and labor conditions, however, are not favorable for extensive zinc production in Germany. Although the ore is found in nearly every country in the world, the deposits in the United States and Germany alone of the chief smelting countries are sufficient for domestic requirements. Australia, the third largest producer of zinc ore and concentrate, has but a small smelter capacity and consequently has been Europe's chief source for foreign ore.

The attached table shows the exportation of zinc slabs and sheets from the United States:

Country	*1910-14 (5-yr. aver.)	*1918	*1919 (first 8 mo.)	*1920
Belgium	20	3,725	3,965	
Denmark	311	908	692	
France	35,513	34,493	24,768	
Italy	7,667	12,091	1,384	
Norway	41	342	869	149
United Kingdom	5,632	35,774	59,489	68,253
Canada	4,601	8,048	3,746	1,363
Mexico	1	1,762	1,013	503
Argentina	8	583	735	861
Brazil	6	682	625	591
Japan	485	5,298	20,043	3,461
British South Africa	2,097	1,297	11	
Portuguese Africa	659	322	3	
Other Countries	262	2,077	2,608	2,973

Total

*Fiscal year ending June 30. †Calendar years.

The table shows how greatly Europe has come to rely upon American production for its zinc. The United Kingdom has regularly been the chief customer for American zinc, but the increase from an average of 5682 tons before the War to 59,489 tons in 1919 and 68,253 tons in the first eight months of 1920 is very striking.

Eastern Metal Market

New York, October 27.

Lack of demand still characterizes all the markets, and prices have fallen in all metals except tin.

Further offerings of copper have lowered values, and consumers continue out of the market.

The tin market has strengthened to some extent, but buying is on a small scale.

Conditions in the lead market are unchanged, but prices have fallen.

The zinc market is stagnant and values are a little lower for the domestic metal.

Antimony is stationary.

IRON AND STEEL

With no increase in new business, the downward tendency of iron and steel prices has been more pronounced. In coke, which has been the key to high pig-iron prices for months, the week has brought a further decline of \$4 per ton, making a total of \$6 in two weeks.

More mills have reduced output. Some of the lesser steel plants in the Pittsburgh and eastern Ohio districts have been more than 50% idle and six blast-furnaces in those districts have blown-out. The Youngstown plant of the Carnegie Steel Co. is operating but half its open-hearth furnaces. No change has been made in the Steel Corporation's price policy and any expectations of an advance by the corporation still centre in rails, concerning which an announcement is looked for before the end of the year.

Export sales have fallen off in a marked degree this month, the unfavorable credit situation creating an embargo against a growing list of countries. However, figures for September and October are expected to show shipments up to the average of more than 400,000 tons for each of the previous four months. Europe's markets remain in line with events here. Stagnation and plant shut-downs mark the situation in Great Britain and prices are weaker.

COPPER

The market has continued to decline until now either Lake or electrolytic copper can be bought at 15.25 to 15.50c., New York. This has been brought about by further offerings by various sellers, some of them large producers but the buying power is absent. Consumption has also declined and there is no denial that the stocks, or surplus, are large. How large they are it is difficult to say or ascertain. Certain press reports place it as 600,000,000 lb. In any event copper is below the cost of production for at least many companies and it is certain that the output will be curtailed further if it has not already been. Some companies are liquidating their surplus, or part of it, while others will not. The price is now down close to the low mark of 1919 and by many it is thought to have dropped too far. Whether the bottom has been reached it is difficult to say. About a week ago there was some spasmodic buying around 16c. but this has vanished. Better times are confidently predicted within a few weeks.

TIN

A moderate business was done the latter part of last week with dealers the principal buyers, but the British coal strike has put a further damper on business and this activity has disappeared. Those who did the buying considered tin cheap under 40c. and are looking ahead to higher markets or covering short speculative accounts. There were temporarily more buyers than sellers. On the New York Metal Exchange dealings are more numerous and totaled in the last week more than 150 tons. Of this two lots of 25 tons each of spot Straits tin were sold under the rule at 39.55c. and 39.30c., respectively. There were sales of future ship-

ment of December-January at 40.37½c., of November-December at 39.75c., and of October-November Straits tin at 40.50c. A favorable outcome of the British coal strike is expected to send tin higher. Yesterday London prices took a decided jump, ending about £7 per ton higher than a week ago. Spot standard was quoted at £258 10s. per ton, future standard at £263 10s., and spot Straits at £260. These are all about £17 per ton higher than a week ago or on October 19. Arrivals thus far this month have been 1700 tons, with the quantity afloat 5025 tons.

LEAD

Demand continues light and the market is dull and easy. Domestic lead is lower and can be bought on a basis of 6.75c., St. Louis, or 7c., New York. Sales have been made at these levels. We quote the outside market at 6.75c., St. Louis, and 7c., New York. The leading interest continues to maintain its quotations at 7c., St. Louis, or 7.25c., New York. Imported lead is still available at 7c. on dock, duty paid, but the cost of importing is now less than this and therefore it is less of a factor than formerly. Importations on contract still continue.

ZINC

Prime Western for early delivery is easier and is obtainable at 7.10c., St. Louis, at which level small lots have been sold. Business is very light and producers continue their uninterested and waiting attitude, selling only what they must to cover immediate needs of regular customers. They refrain from quoting future positions. The same grade of zinc, sold for export and re-shipped to this country, is still available at 7.50c., New York, which we quote as the New York or Eastern market, but the quantity available is less than formerly, actual sales having disappeared some three weeks ago, but shipments are still being received.

ANTIMONY

Wholesale lots for early delivery are unchanged at 6.50c., New York, duty paid, with demand light.

ALUMINUM

The leading producer continues to maintain its quotation for virgin metal, 98 to 99% pure, at 32.90c., New York, for wholesale lots for early delivery. Other sellers are offering the same grade, mostly imported, at 28.50 to 29.50c., New York.

ORES

Tungsten: The market is stagnant and prices are nominal with Chinese ore quoted at \$4.50 and Bolivian at \$5 to \$5.50 per unit in regular concentrate.

Ferro-tungsten is quoted at 90c. per lb. of contained tungsten guaranteed with 70c. asked for the unguaranteed while the powdered product is held at 78 to 85 cents.

Molybdenum: There have been offerings but no buyers and quotations are nominal at 75c. per lb. of MoS, in regular concentrate.

Manganese: There have been further sales of several thousand tons of foreign ore shipped to the United States at concessions from the previous prices realized. It is not possible now to state the consideration. The market is, however, generally weaker.

Manganese-Iron Alloys: There has been no change in the ferro-manganese market, the standard product being quoted on a basis of \$170, seaboard, for either the domestic or foreign product. Re-sale alloy is still available in limited amounts at \$155 to \$160. The spiegeleisen market is lower and the high-grade product available and sold at considerable concessions below the hitherto prevailing price of \$82.50, furnace.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE LUDLUM DYNAMOBILE

This new mobile power unit was designed and built by the New York Engineering Co., 2 Rector street, New York, for driving the small portable conveyors used in certain classes of mining in South Africa. Previously, power for this purpose was furnished by the old-fashioned reciprocating engine and portable boiler, with belt and pulley transmission to the conveyor. The object of the Ludlum dynamobile is to realize the utmost economy in generating power, and high economy and great flexibility in delivering that power to the driven mechanism.

The dynamobile consists of a special type of Ludlum

rough roads would break or dislodge a fire-brick furnace-lining.

The high efficiency of the boiler and turbo-generator set, and its compactness and light weight, makes the dynamobile a most economical and desirable unit for portable-power purposes, as it can be placed near its source of fuel and its power electrically transmitted to any reasonable distance with minimum loss. It is expected by the builders that this new high-duty portable plant will supplant the European outfits known as locomobiles and extensively used in foreign countries. The latter consists of an internally fired boiler of high efficiency with a reciprocating steam-engine, and contains many refinements making for economy; and in spite of the fact that it is very heavy and costly, it has found extensive use abroad because of its economy. The weight of the Ludlum dynamobile is only about one-third that of the locomobile and its price is much lower, while its efficiency is even higher than that of the European unit. The outfit illustrated is of 10 kw. capacity. Larger units up to 200 kw. are furnished, either A. C. or D. C.

TESTING OIL-SHALE

The Denver Fire Clay Co. gives the following method for preliminary or field distillation of oil-shales.

Before proceeding with the analysis the operator should understand that oil-shales do not contain oil as such. The oil is present in a substance known as 'kerogen' and can be removed by heating, without the presence of air, or destructive distillation, as the process is called. The method and rate of heating is very important, and upon this factor depends largely the type of oil that is produced from the shale.

To determine the oil-content of shale, first take a representative sample of the ledge and crush the shale so that it will pass through a $\frac{1}{4}$ -in. mesh sieve. Thoroughly mix the crushed shale and weigh out exactly $8\frac{1}{2}$ oz. Place this unit of $8\frac{1}{2}$ oz. in a one-pint or a one-quart (the latter is preferable) iron retort. Seal the cover with our special cement, or with an asbestos gasket. If the distillation is to be conducted in the field, place the retort containing the charge of shale in a fire-clay furnace body. Connect a $1\frac{1}{2}$ -in. iron condenser to the outlet from the retort, and have it slope about 40° from the horizontal. A two to five-gallon water-reservoir should be mounted at a somewhat higher level than the condenser. This may be connected to the condenser by means of rubber tubing and then, whenever the water in the condenser becomes warm, it can be replaced by cool water from the reservoir simply by opening a pinch-cock. Place a 100-cc. graduated cylinder at the discharge end of the condenser, set the burner in place, and the apparatus is ready to use.

The best source of heat for field or laboratory use where gas is not available, is the $1\frac{1}{2}$ -in. DFC hydrocarbon burner, using gasoline for fuel. After one is familiar with the use of the apparatus a distillation can be made with from one to one and one-half pints of gasoline. Be sure that all joints are tight, then begin the distillation, turn the burner on full force, and leave the flame on full until the first drop of

Ludlum Dynamobile

water-tube marine-boiler, a steam turbo-generator unit, switchboard, boiler feed-pump, feed-water heater, condenser, and, where the highest economy is sought, a superheater—all mounted on a steel frame carried on wheels. It is extremely simple in construction and in operation, is free from vibration, and is practically 'fool-proof' in construction. In the dynamobile illustrated, the boiler was designed for burning wood, the combustion-chamber being unusually large, but the outfit can be furnished for burning any kind of fuel. The combustion-chamber is entirely surrounded by the water-filled steam-generating parts of the boiler—this not only assuring high economy but also doing away with all fire-brick lining. The latter feature is of special value in a portable plant like this, as transportation over

water or oil appears in the graduate, then turn the burner as low as it will burn. The best results with the DFC burner will be obtained if the pressure tank is kept within the range of 45 to 55 lb. Keep the oil dropping from the condenser at regular intervals, but do not run it out too fast or the oil will be 'burned'. As the flow becomes sluggish, slightly increase the fire under the retort. Be sure to watch the condenser at all times and not let it become too warm, or part of the oil will pass out as a gas and not condense. After the oil has stopped flowing and the bottom of the retort is a bright red hue, shut off the heat, for nothing is to be gained by heating beyond this point.

The number of gallons of water and oil contained in a ton of the shale retorted, can be read directly from the graduate, for, if 8½ oz. is taken from the charge, then each cubic centimetre of oil which collects in the graduate is equivalent to one gallon per ton. The line of separation between the oil and water can usually be seen at once. If not, stir the contents and let the graduate stand for a short time and the division will become quite sharp.

The gravity of the oil may best be determined by pouring about 30 cc. of the oil into a glass cylinder, and then measuring the gravity directly by the use of a small hydrometer. It is desirable to use hydrometers which contain a temperature correction scale, especially when working outside during the hot summer months.

CUTTING A 44-INCH RISER

Heavy cutting with the oxy-acetylene flame has become so common that today nothing short of a super-cut attracts particular notice. A real super-cut was made recently in the plant of the National Car Coupler Co., at Attica, Indiana, when a cutter operating an Oxyweld blow-pipe tackled a 44-in.

fied. To offset this difficulty the operator resorted to first cutting the corners of the riser so as to reduce the uncut cross-section to a smaller square. This operation was repeated until the remaining stem could be easily cut through. The equipment consisted of the Oxyweld cutting blow-pipe, Linde oxygen, and Prest-O-Lite dissolved acetylene. In this manner it would appear that there is no limit to the thickness of steel that can be cut with the oxy-acetylene torch, as the operation of slicing off angles can be carried to any desired extent so long as access to the metal with the cutting-flame is provided. With the injector type of blow-pipe the 'reach' of the flame enabled the operator in this instance to carry out the work by simply directing the jet through the initial kerf.

COMMERCIAL PARAGRAPHS

The Pennsylvania Pump & Compressor Co. has recently issued a number of bulletins describing its air-compressors and centrifugal pumps with details of their construction.

'Troy Trailers' is the title of a comprehensive publication issued by the Troy Wagon Works Co., of Troy, Ohio. It points out that trailers should be specifically designed for the use desired, and detailed specifications are given of a number of typical designs, especially of contractor's side-dump ore-wagons. The publication is well and freely illustrated.

'Forged Fluid End Pump' is a 36-page bulletin (D-1302) distributed by the Worthington Pump & Machinery Co., New York. It refers especially to heavy-duty pumps and to those working under pressures up to 10,000 lb. Pumps for oil pipe-lines and deep mines are standard equipment in this line, as also are high-pressure pumps for hydraulic installations.

The Pelton Water Wheel Co., of San Francisco, has issued a 48-page 'album' of views portraying typical installations of Pelton equipment of various sizes, from small units, driving excitors, up to the Drum plant of the Pacific Gas & Electric Co. with two 20,000-hp. turbines operating under a 1400-ft. head.

The present interest in oil-shale has moved the Denver Fire Clay Co. to issue a nifty bulletin (No. 25) on 'Oil-Shale Equipment'. The title is somewhat misleading in that it really gives interesting reference to information on the testing of oil-shale, the 'equipment', which is, of course, the Denver Fire Clay Co.'s apparatus, occupying but a small part of the bulletin.

Engineers and architects who are concerned with heating and ventilating-problems will be interested in a recent publication (68 pages) of the Buffalo Forge Co., called 'Standard Pipe-Coil Heaters'. This publication, although called catalogue No. 460, has been filled with curves and tables to make it really useful, commencing with 'How to Figure Heater Requirements' to 'Final Temperatures and Condensations', and 'Properties of Air'.

Barber-Greene Co., Aurora, Illinois, has recently published its catalogue No. 4 of standardized material-handling machines, more particularly self-feeding bucket-loaders and portable belt-conveyors. The catalogue is filled with good illustrations of typical arrangements, and anyone interested in handling ore to or from stock-piles, cars, and storage-beds, or in excavating for foundations or building roads, will find much to interest him in the 32 pages of this publication.

The introduction of pulverized coal as a fuel has attracted attention to the difficulty of accomplishing the necessary drying of this inflammable material in an economical manner. Ruggles-Coles has issued its 'Catalogue Sixteen', which, although dealing with dryers for everything from aluminum hydrate to pitch and residuum ore, includes one class intended for drying combustible materials by direct heat, which obviously ought to be the most economical method.

Oxyweld Apparatus in Operation

(square) steel riser. The cut was rendered more difficult because of the upright position of the riser, which necessitated a horizontal cut. If the riser had been horizontal and the cut vertical the operation would have been much simpler.

T. A. RICKARD, Editor

HOW ignorant even well-informed persons can be concerning simple facts of industrial geography is suggested by a paragraph in the 'Boston News Bureau' expressing the hope that "the average Cornwall pit boy" will get hold of the idea that "the coal peace referendum is of rather more importance than a game of cricket". Cornwall is a land of granite and gneiss, in which veins of tin and copper may flourish, but not beds of coal.

DISMISSAL of the cases against all the remaining defendants held in connection with the Bisbee deportations of July 12, 1917, is announced from Tombstone, Arizona, where several of the cases arising out of that deplorable affair have been tried abortively. We are glad that the scandal has been quieted, for while we recognize that there was great provocation and some excuse for the exercise of violence against the alleged agitators and I. W. W., there can be, among good citizens, nothing but regret that any group of reputable men should take the law into their own hands.

FINANCIAL affairs in the United States cannot be understood without some knowledge of our Federal Reserve system of banking. It gives us much pleasure therefore to give our readers, in this issue, an article on this important subject by Mr. Edward Elliott, a director of the Federal Reserve Bank of San Francisco. Opinions may differ as to the complete success of the present banking structure and we are well aware that there be those who are critically disposed in this matter, but for ourselves we are inclined to give the Federal Reserve system credit for the stabilization of financial conditions in recent years, more particularly for the absence of panic during the crisis of the War and for the wonderful results obtained from the issuance of Liberty bonds.

ANNOUNCEMENT is made that the British government has lifted the embargo upon American exploitation of oilfields in British territory. This is a friendly and a wise step; as we have insisted more than once, it does not matter who exploits a country's mineral resources so long as the product goes into the home market; for example, it is not in accord with the national welfare to allow a British company to take oil from California to London, but any winning of oil in California by a foreign operator is unobjectionable, if not, indeed, desirable, so long as the product remains here for use by our own

people. If foreign capital can be employed to develop a domestic mineral deposit, it is to our gain, provided the capital of our own people is remuneratively employed in other enterprises. If, however, we wish to guard against the exhaustion of a specific mineral resource, it matters little whether it is due to the operations of our own nationals or of foreigners. Our supply of oil being precarious, we ought to restrict exportation.

COPPER SHARES are in the dumps; on October 28 twenty of them averaged \$29.51 as against an average of \$72.14 in November 1916, when the artificial stimulus of war speculation sent them heavenward. Liquidation has been persistent and steady of late. The announcement by the Government that 574,000,000 pounds of copper has been reclaimed from new and old scrap during the past year was a shock to the market. This is a time to buy copper shares. The depression cannot last. A demand for metal on the part of the traction and telephone companies will make itself felt as soon as the public utility companies raise the fresh capital needed for the purpose. Now that the election is past and the movement of crops is nearly completed there should be signs of activity in this direction. The country is growing and its activities are expanding continually. These consume an increasing quantity of copper. And then there is the European market, which, so far, has been a cruel disappointment to the producers of copper, simply because we are still technically at war with some of our best customers.

UNDER 'Discussion' we publish a courteous demurrer from Mr. Charles K. Field, the editor of the 'Sunset Magazine', in reply to sundry criticisms, particularly from Mr. von Bernewitz, on his biography of Mr. Hoover. He makes so good a case that there is not much that we care to say, except that Mr. Wilson, whom he quotes as his authority for the details of Mr. Hoover's career in Australia, makes the blunder of assuming that Mr. von Bernewitz is a German. Names are unsafe indicators of nationality. Sometimes we think that people of obviously alien name ought to change it when they become naturalized as American citizens, but that, of course, is a matter of taste, and therefore not disputable. Mr. von Bernewitz, as our readers know, was formerly a member of our staff and before that he was our correspondent at Coolgardie, so he is likely to be well informed concerning

the matters on which he wrote. The present writer was at Coolgardie in 1897 and appreciates as well as anyone what Mr. Hoover accomplished in the way of improving the management of the mines under the control of Bewick, Moreing & Co. We know that Mr. Field had access to authentic data, and we do not doubt that Mr. Wilson proved helpful in technical matters. The 'life' appearing in the 'Sunset Magazine' was incomparably the best published during the period when it seemed likely, and we hoped, that Mr. Hoover would be nominated for the Presidency.

The Election

The result confirms the anticipations of most unprejudiced observers; it is an overwhelming victory for the Republican party. It is as well that the new President should have the backing of a Congress in which his own side is dominant. This will promote effective legislative action and place the responsibility squarely where it belongs. One of the anomalies of our political system is the possibility of a President being in office when the majority in either or both houses of Congress is in opposition to him and to the party that elected him. The result of the election is not related to the character or ability of either candidate; it hinged upon the personality and performance of the outgoing President. His position at this time has the elements of a Greek tragedy; only a mean man can fail to appreciate its intense pathos. He has had the solemn referendum for which he asked, and the American people, whom he represented with so great an authority and impressiveness before the world only a short time ago, has cast an unprecedented vote against his administration and his policy. He has been the victim of an extraordinary reversal of sentiment; he has been subjected to the most vicious personal attack and the most bitter condemnation at the hands even of his own friends. We deplore the vendetta that the senatorial camarilla waged against him, and the effrontery with which the President of the United States has been labeled un-American. With most of his policies we were never in sympathy; for his irresolution before we went to war we had a feeling of resentment; we did not respond to his idealism and we did not admire his obstinacy, but he has played a great part in human affairs and he has devoted himself with intense sincerity to the service of his country; therefore at this moment he seems to us a nobler figure than any of his detractors. He is a wreck, a pitiable wreck physically and almost broken mentally. Several of those who have seen him recently have recorded their impressions. He is stricken, aged, worn; his face is drawn and haggard; his eyes are dull and his voice is weak. A little over a year ago many of us saw him splendidly alert and vigorous, mentally and physically, a fine figure of a man. He sacrificed his health and his political career for the sake of the idea that was nearest to his heart. Today he is broken, humiliated, all his hopes shattered, all his policies frustrated, all his dreams ridiculed. We salute him with the deepest respect and the profoundest regret.

The Bounty on Gold

This is to be a special topic of discussion at the meeting of the American Mining Congress. As part of the record in the case we publish the report presented to the Secretary of the Treasury by the committee appointed to investigate conditions in the gold-mining industry; it seems to have been overlooked in the current discussion of this interesting subject. On that committee were two mining engineers, Mr. Emmet D. Boyle, the Governor of Nevada, and Mr. Pope Yeatman, a leader of the profession. The chairman was Mr. Albert Strauss, formerly a member of the Federal Reserve Board. Another member was Mr. Edwin F. Gay, formerly Dean of the Graduate School of Business Administration at Harvard, and now editor of the New York 'Evening Post'. To these was added Mr. Raymond T. Baker, the Director of the Mint. Evidently the committee was one well fitted to advise the Secretary of the Treasury. It will be noted that the report discusses the relation between the amount of gold available in a country and its credit during time of war. The structure of credit is bound to be high if the community—and the Government, we may add—is extravagant. Even the least observant will concur with this dictum, especially if the truth of it be impressed upon him through his pocket nerve. In time of peace, however, no impairment of confidence is threatened by a decrease in our gold production, says the committee. The question arises, are we at peace? Technically, we are not. Even if we were, would the conditions be those normal to a time of peace? Again, the answer is in the negative, although we agree that "in due time" there will ensue a restoration of all industry, including gold mining, to "a normal basis". It is the judgment of the committee that no steps should be taken by the Government to stimulate the production of gold. We are not surprised at this conclusion, for any interference with the buying and selling of gold, anything that affects our free market for gold, is not to be risked except under stress of acute necessity. This view, of course, is opposed by Mr. Louis T. McFadden, Chairman of the Committee on Banking and Currency in the House of Representatives, and the author of the Bill for paying a bounty on newly mined gold out of the proceeds of an excise-tax on the metal used in manufacture. In a hearing before the Committee of Ways and Means, he argued that the gold-mining industry would soon be "completely shut-down" unless assistance were forthcoming from the Government, and that the national credit was being impaired "by excess exportation and industrial use". Between May 1919 and May 1920 the monetary gold stock of the United States suffered a loss of \$443,000,000. During 1919 the gold sold by the Mint for consumption in the arts amounted to \$76,837,600. The output of gold in this country before economic conditions were changed by the War was \$100,000,000; now it is half that. Suppose we restore production to the ante-bellum basis, that is, add \$50,000,000 to our present output. What does that mean? As much as \$50,000,000 of gold has been received at New York from Europe in one month; a single ship

has landed \$17,000,000 in one day. Our foreign commerce amounts to \$14,000,000,000 per annum. One must have a sense of proportion in matters of this kind.

Will the gold produced in the United States be available as a monetary reserve? Not necessarily; the amount of gold remaining in a country bears no relation to its production. The metal mined in South Africa is coming here; it does not remain there, nor does it stick in London. We question whether the gold reserve of the United States would be better protected by the McFadden bill, because our domestic output of gold, like that of South Africa, follows the tide of international trade. Suppose we do increase our production by \$50,000,000; it will be effective only in so far as it increases the world's total stock of gold, which amounts to nine billion dollars worth. The ratio is \$50 to \$9000. At the end of last year just about half the visible supply of gold was in the United States. The world's total production up to 1919 is estimated at 19 billions, so that ten billion dollars worth has gone into the arts, has been hidden, or is lost. What has played havoc with the gold standard is not so much the decreased production as the enormous absorption of gold for hoarding and other non-monetary purposes in India and the Orient generally. Between 1914 and 1919 India absorbed half the world's production of gold during those five years. In the Malay States an American \$5 gold-piece is at 25% premium over a five-dollar bill, because the natives want it to put away and to use for jewelry, the latter being a form of hoarding. A \$20 gold-piece is at a premium of 5% only, because it is a unit too large for the average native. As Mr. Henry Strakosch has pointed out, the cheapening of gold in terms of commodities has enabled the Eastern peoples to pay more for it than the Western peoples are willing to give in order to secure it for monetary purposes.

A good deal of nonsense has been talked about Great Britain paying a premium on the gold mined in South Africa. Great Britain is paying no premium on gold. What has happened is that the British government removed the war-time restrictions upon free trading in gold and thereby bared the artificial status of the paper pound sterling, which at once was found to be at a discount in terms of gold or in terms of the dollar, which remained at a parity. The pound, the franc, the mark, and the lira have lost their purchasing power more than even gold has done, while the American dollar has become the standard monetary unit. When the miner at Johannesburg can sell his metal in London for 122 shillings, for example, as compared with the normal pre-war price of 84 shillings, he gets a premium of 45 $\frac{1}{4}$ %, and as he pays for his labor and supplies in shillings, his profit is increased in proportion to the premium, which exactly measures the discount at which the pound stands in relation to the dollar, that is to say, the percentage of discount on British currency in terms of gold bullion is equal to the percentage of discount on sterling exchange in terms of American dollars. When gold sells for 122 shillings in London, the pound is worth only \$3.38 in New York. If he buys machinery in the United States,

the South African operator finds that his money brings him just as much less in dollars as his gold fetches more in shillings. If a Californian sells his gold in London he is paid in paper pounds and when he converts them into dollars, he finds that he has received \$20.67 per ounce, less the cost of shipment and insurance, that is, he has received the price that the U. S. Mint is ready to pay him any day. If he buys machinery or supplies in England, he gets the benefit of the premium on the dollar or on gold, as you like to look at it. In regard to the so-called British gold supremacy, that also is a misleading phrase. In 1919, it is true, the United States produced only 16.6% of the world's output, whereas the British dominions produced 67%; but even that largely preponderant portion of the total production did not suffice to keep the pound sterling on a par with the dollar; in short, the supremacy of the dollar is a fact and "British gold supremacy" is a fancy.

It is asserted by our friends that our gold is needed to maintain the national monetary reserve. The bankers demur to this. A special committee of the Bankers Association has reported itself as "unalterably opposed" to the McFadden bill. It seems obvious that our domestic production of gold is no more likely to fortify our monetary reserve than the gold we import, on trade balances, from South Africa. The real thought behind the McFadden bill is to assist a worthy industry that is suffering from the abnormal economic conditions created by the War. We have more than a friendly interest in the gold-mining industry and we desire heartily to see it assisted in any way possible, short of doing anything injurious to the country as a whole. The best way to help gold mining, and copper mining, is to make peace with the countries with which we are still technically at war and to take steps that will stabilize peaceful relations between the others, and between them and ourselves. In short, the cure for the decadence of gold mining is normal economic conditions.

From Leadville to Cyprus

The mining engineer makes the whole world his patrimony; the American members of the profession have lived up to this tradition in recent years, although previously they were more stay-at-home than their English friends, for the good reason that our country happens to be continental in its extent and mineral resources. Lately the American has been directing mining operations in the remotest corners of the earth, from Okhotsk to Tanganyika, from Suan to Chuquicamata. He has also investigated the ancient mining districts of that cradle of civilization, the Mediterranean. Not long ago we referred to the exploratory work done by engineers of the General Electric Company on the Sinai peninsula; this week we give sundry particulars concerning prospecting in old workings on the island of Cyprus. The information comes in the course of an interview with one of the leaders of our profession, Mr. Seeley W. Mudd, now a resident of Los Angeles. As a man is more interesting than a mine, so Mr. Mudd is more engaging than a

Cypriot prospect; or if you like to look upon a man as a 'prospect' in another sense, then you will find that the sample we have taken pans well; it shows the pure gold of good citizenship. Mr. Mudd is evidence for the efficiency of the American melting-pot; his forbears came from several racial stocks, which have been so roasted, smelted, and refined in the laboratory of American life and tradition that the product, after two or three centuries, is an unmistakable type, the *civis Americanus*. Mr. Mudd had the best education available in his youth, but he recognizes how much the technical training of today is better than that of forty years ago. Later he underwent an apprenticeship that an intelligent member of the younger generation might well envy. In the first place, he had a chance to do all kinds of work in a smelter immediately after leaving college, and then, when he went to Leadville, he engaged in the leasing of mines on his own account. We regard leasing as an invaluable experience, because it helps a young engineer to acquire judgment and initiative, besides teaching him unforgettably that the purpose of mining is to make money. It is not given to every young man to engage in mining on his own account, for to do that he must have some capital, but if he can obtain the experience it is likely to make him a reliable consultant in after years, provided the pursuit of wealth does not make him a wild optimist, which is the result of the *sacra fames auri*, as, indeed, of the hunger for baser metals. In our published interviews with successful engineers it will have been noted how often a successful turn in a man's career is due apparently to an accident. Mr. Donaldson chose to go to the mine in Oregon, thereby resigning the management of the Small Hopes to Mr. Mudd. On his connection with that famous mine he laid the foundation of his career. First he had the experience of managing the Small Hopes in its bonanza stage and later as a depository of low-grade ore. He was given charge of other mines distinguished by a variety of geologic structure and operated under diverse economic conditions. His leasing operations, as we have said, were particularly valuable in developing the qualities of discrimination and sagacity that became personal characteristics as he advanced in his career. In the end he became connected professionally with the biggest mining ventures in the West. The Ray laid the basis of his personal fortune. It is interesting to note his confident foresight in contrast with the narrow vision of the former British owners; when worked on a small scale as a high-grade deposit, the mine was a failure, but when exploited as an immense deposit of low-grade ore it was made enormously profitable, thanks to the constructive imagination of an alert and experienced engineer. An English mining engineer of recognized ability and high character, the late Alexander Hill, opened up the Ray in the first instance, unfortunately too soon to take advantage of the improvements in technical practice, in mine and mill, that made it possible to exploit copper ores with a cheapness now no longer remarkable. Mr. Mudd's adventure in the United Eastern was a smaller affair, but likewise extremely profit-

able. We have heard it said that the United Eastern, in plan and execution, was one of the neatest mining enterprises ever started and brought to fruition by one man or a group of men, for in all his operations, of course, Mr. Mudd has had the loyal assistance and intelligent co-operation of several friends, also mining engineers. That points at another characteristic invaluable in all kinds of large endeavor: he aroused loyalty and won whole-hearted assistance in his work. He does not play that miserable game called 'the lone hand'; he likes to have partners and he does not forget them in the hour of success. Moreover, the younger men tell us that he goes out of his way to help them and that he remembers his obligations beyond the letter of the contract; in consequence, he has what is too often denied to the rich and successful: he has the respect and affection that no money can buy. In his engineering work, when appraising a mine or in planning a scheme of operations for a new mine, he shows the care and caution that the circumstances require; he has no use for hearsay or guessing; he anchors his plans to the facts as determined by thorough investigation. He is not an optimist, nor a pessimist; he has a sense of the value of proportion. He can see the other man's point of view; and that makes him tolerant. A quiet philosophic appreciation of things as they are renders him fair in his judgment of the issues arising between capital and labor. His remarks on this subject indicate humaneness; they suggest that some men can acquire the privileges of wealth without forgetting their obligations as employers of labor. Entering always, in the later years of his life he has engaged in a romantic mining venture in Cyprus, where he, Mr. Philip Wiseman, and other friends have uncovered and explored sundry ancient copper diggings. He gives an interesting account of them. During the War this enterprise had troubles of its own, as might have been expected, but he forgot them in his devotion to the national service. As early as August 1916 he applied for a commission in the Engineer Officers Reserve Corps, and on February 12, 1917, he received his commission as a Major. In 1918 he was made a Colonel in the U. S. Army. He was assistant to Mr. D. C. Jackling, the Director of the Government Explosive plants, who had supervision of the building of the big Nitro works in West Virginia, a part of which only could be shown in the photograph that we print with the interview. In his concluding remarks Mr. Mudd exhibits the essential sanity and the cheery outlook that have marked him during the whole of his career. He believes in mining and has a worthy son to follow in his footsteps; he recognizes the broadening of the mining industry and the enlarged scope for engineering on a big scale; he is of the opinion that the code of conduct among members of the profession has improved. He has helped to improve them. He can look back and be grateful for unusual opportunities and remarkable good fortune, but most of all he is happy in having found work and opportunity for others, and for the many friends he has made. He has more than he knows.

DISCUSSION

Mr. Hoover's Biography

The Editor:

Sir—Some time ago you printed a communication signed Max von Bernewitz in which your correspondent complained at the "rubbish" contained in the biography of Herbert Hoover, published in the 'Sunset Magazine'. As examples of this rubbish your correspondent quoted our statement that Bewick, Moreing & Co. had an office at Coolgardie, whereas they had no office there and we should have said Kalgoorlie; also our statement that Mr. Hoover found that the miners were using the old 'double-jack' and that he introduced the single-jack into the mines and faced a rebellion of the miners.

In an editorial you commented very kindly on the quality of the biography we published, but you said, "Of course, the suggestion that Mr. Hoover or anybody else from the United States introduced the single-hand drilling practice into Australia is ridiculous. It was introduced into Australia, and into California, by the Cornish miners before Mr. Hoover was born," and further, "The pity is that these writers did not submit their manuscript, if not to their victim, at least to some competent mining engineer and one acquainted with Mr. Hoover's career in foreign lands."

I desire to say first that it was not intended to suggest that Mr. Hoover did more than introduce single-hand drilling into the mines immediately under his management; and, secondly, that it was not feasible to submit the text of this biography to Mr. Hoover himself because the author's method was personal and intimate in the extreme and it would have been a presumption to attempt to make Mr. Hoover in any way a party to any portions of the text as that might imply responsibility on his part for a variety of other details. But really, we did the next best thing in the interest of accuracy. In the case of the Australian chapter, regarding which your correspondent complained, the material was in the first place obtained almost entirely from George B. Wilson, a mining engineer, who was a college mate of Herbert Hoover at Stanford University and who was with him during practically the entire period of his residence in Australia, and in China as well. Not only did Mr. Wilson furnish the material, but he carefully read the galley-proofs. These proofs were also read by Theodore Hoover, Herbert Hoover's brother, and himself a mining engineer.

Mr. Wilson has made the following comment upon the communication and editorial in your journal to which I have referred:

"I read with interest the criticism in the 'Mining and

Scientific Press' of August 28 of your biography of Herbert Hoover. Such contributions add nothing to the facts and belong to that class of criticism which discourages the publication of much valuable information.

"I am inclined to disregard all of Max von Bernewitz's statements, as his suggestion that Bewick, Moreing & Co. did not have an office in Coolgardie during the period in question proves quite conclusively that he does not know what he is talking about. Not only did they have large offices, assay-offices, and an engineering department in Coolgardie but they had no office in Kalgoorlie during 1897, if you except the office of the Hannan's Brownhill mine, which they managed.

"Plainly Mr. Max is guessing, but I am surprised at the editorial suggestion that single-jack drilling was universal in the mines of West Australia in 1897. I use the word suggestion advisedly because the editorial refers only to the introduction of single-handed drilling into Australia by the Cornishmen, which is cheerfully granted. However, the Kalgoorlie mines at the time in question contained as many aeroplanes as they did single-jack hammers. Mr. Hoover first introduced the single-hand hammer in the East Murchison United mine at Lawlers and it was here that the miners regularly buried them in the 'mullock' left in the stopes.

"I do not regard your article as in any way criticizing the Australian miner. The mining camps of West Australia were comparatively young in 1897 and their rich ores had rendered unnecessary a high degree of refinement in operation. In 1897 depth was being obtained in the development of the mines and the values were diminishing as the surface enrichments were being depleted. This rendered necessary the improvements in method and economies of operation which Mr. Hoover vigorously introduced. Nearly every mining camp in the United States has a similar history of early profligacy succeeded by sound methods and close economy as the ore values declined, and it is no reflection on the early management to relate this history.

"I note the editor's suggestion that you should have submitted your manuscript to some competent mining engineer acquainted with Mr. Hoover's career in foreign lands. As I am responsible for many of the facts contained in your description of Mr. Hoover's Australian and Chinese careers, including the facts previously commented upon herein, and because I carefully read your galley-proofs, I think you may claim to have forestalled Mr. Rickard's suggestion unless he takes issue regarding that word 'competent'."

We have been very appreciative of your commendation

of 'The Making of Herbert Hoover' and I hope your interest in the biography may be enhanced by this illustration of the pains we took to ensure its accuracy.

San Francisco, November 3. CHARLES K. FIELD.

[Mr. Wilson prefixed 'Herr' to Mr. von Bernewitz's name, and we deleted it, knowing that Mr. von Bernewitz is a native of New Zealand. We refer to Mr. Field's courteous letter on the editorial page.—EDITOR.]

Distribution of Power in California

The Editor:

Sir—In the issue of your journal of October 30 appeared an editorial reading in part as follows:

"As soon as the recent rains started to swell the mountain streams the State Railroad Commission gave permission to the 'movies' to run longer hours and to the merchants to light their show windows and electric signs more freely, but left the mining industry 20% short of its normal power."

To those unfamiliar with the facts this might be taken to indicate that the mining industry was being discriminated against and that the restrictions were still in force, although elsewhere in the same issue two separate items stated that the removal of power restrictions had permitted two mining companies to resume their normal method of operation.

During the summer restrictions affected the use of power during twenty-four hours of the day. Rains prior to October 11 made it possible on that date for us to remove restrictions from five P.M. to seven A.M. This applied to mining and all other industries, as well as the 'movies' and sign and window lighting. Two days later further rains enabled us to remove all restrictions except skip stops on the street railroads, and these were removed on October 17. Since that date no restrictions whatever have been in force.

The California Metal and Mineral Producers Association, which was in close touch with the power situation throughout the summer and actively co-operated with us to the end that the restrictions might fall as lightly as possible on the mining industry, feels, I believe, that no discrimination was intended or practised against that industry.

H. G. BUTLER,

San Francisco, November 3. Power Administrator.

Roasting and Chloridizing of Bolivian Silver-Tin Ores

The Editor:

Sir—I hope you will allow me some comment on the way in which my paper on the above subject has been abstracted in your issue of September 11. That part of my paper which deals with the unsuccessful methods of roasting is published nearly in full. However, the solution of the problem by feeding charges intermittently into a straight-line reverberatory furnace where the rabbles do not overlap, and where the state of oxidation of each charge is under positive control by keeping it

separate from the others in its own section, is not emphasized at all, although I believe this to be an entirely new departure in roasting.

Chloridizing-roasting of silver ore has always been a bugbear to metallurgists on account of heavy losses of metal by volatilization. In the furnace which has been developed at Machacamarca silver losses are negligible. When drawings of this new furnace were submitted to one of the largest builders of machinery in the United States, the chief engineer in charge of the mining-machinery department, who himself had considerable experience in roasting, did not believe that the furnace would work. He thought that there would be no advance of ore in the furnace from feed to discharge-end, because the rabbles did not overlap, and that the ore would bank up against the walls, causing breakage of rabbles, etc.

The two furnaces now working at Machacamarca prove the contrary: another furnace with six spindles running on step bearings has been in operation since April and roasts and chloridizes seven metric tons per 24 hours. This is about the capacity that I predicted for a properly constructed six-spindle furnace, in my paper, which was written in December 1919. Several of these furnaces are now being installed at Machacamarca and at the mill of the Cia. Minera y Agricola Oploca de Bolivia, at Chocaya, and I expect that before long they will come into general use in Bolivia for chloridizing and roasting, although their field is not at all limited to that kind of work.

M. G. F. SÖHNLEIN.

Hilversum, Holland, October 3.

MONAZITE is mainly employed for the production of thorium nitrate, which yields thoria on ignition. The mixture of oxides in gas-mantles is derived from a mixture containing about 99% of thorium nitrate and 1% of cerium nitrate. Large residues of cerium compounds are obtained as by-products. The cerium required for the manufacture of the alloy ferro-cerium is obtained mainly from the residues in the manufacture of thorium nitrate for gas-mantles. This alloy typically contains about 30% of iron, and is used in the manufacture of sparking devices. Air-friction causes ferro-cerium to ignite when it is attached to a moving projectile, and for that reason it has been used to illuminate the path of shells. Among other uses of cerium compounds, mention may be made of their use for illuminating purposes in naval search-lights, their application in the manufacture of certain electrodes, and also of their use in medicine to a small extent. A special variety of optical glass containing cerium is made into spectacles for use by glass-furnace operators to avoid injury to their eyes. Monazite is the chief source of mesothorium, which closely resembles radium in its properties, and is obtained from the monazite as a by-product in making thorium nitrate. The amount present is only a few milligrammes per ton of the monzonite, and would be too small to make it worth while to work the monazite for the mesothorium alone. The mesothorium is sold on the basis of its radio-activity compared with radium bromide, and is at present (June 1920) worth from £6 to £8 per milligramme.

Seeley W. Mudd, and Copper Mining in Cyprus

An Interview, by T. A. RICKARD

You were born in the West, Mr. Mudd?

I was born at Kirkwood, a suburb of St. Louis, in Missouri, on August 16, 1861.

You come of English stock?

Of a complex mixture of English, Dutch, Polish, French, Irish, and Scotch. From my mother's side I can claim French Huguenot blood. My paternal ancestors originally came from Poland. On account of religious persecutions they went to England, where they remained for three centuries. When Lord Baltimore came to this country and founded the settlement in Maryland, two brothers of the name of Mudd were in the party, one or both acting in some secretarial capacity. Our family is descended from one of these brothers. A portion of an original grant of land near Baltimore

from Lord Baltimore to one of the brothers is now held by my cousins.

You were educated at St. Louis?

At the Washington University of St. Louis, receiving the degree of Engineer of Mines in the year 1883.

What notable members of the profession were at this college in your time?

William B. Potter was at the head of the mining school. Arthur Thatcher and George C. Stone were assisting Professor Potter. Pope Yeatman, Joseph P. Gazzam, and Edmund B. Kirby were my classmates.

Looking back on this period of preparation, do you feel that the instruction you obtained at that time was suited to the making of your career?

ONE OF THE EXPLOSIVES PLANTS BUILT DURING THE WAR

The course we had at the Washington University was quite similar to and of quite as high a grade as that given in other schools at that period. I owe much to the opportunities I enjoyed there. As compared with the courses now given at the better mining schools it seems, of course, rather crude and decidedly incomplete.

What was your first job after graduating?

Immediately after graduation a half-dozen of us went to Ste. Genevieve, in Missouri, where there was a small copper mining and smelting enterprise under the superintendency of Frank Nicolson. Primarily we learned what we could, but all of us took shifts at the smelter; for some weeks we dumped slag-pots, fired furnaces, and helped generally around the plant. The shaft-furnace made a matte of 20 to 30% copper. This was re-charged into a reverberatory furnace, to be brought up to a black copper through the series of tedious operations then in vogue. The black copper was charged into a furnace like those in the Lake Superior region, and then slowly refined by poling. Occasionally we stayed on shift for 24 hours at a time watching these tedious operations.

You did not stay there long?

No. After leaving there I obtained a job as assayer under Samuel A. Barron, then superintendent for the St. Louis Smelting & Refining Co. at a lead-smelting plant five miles out of St. Louis. At this plant they were just completing some furnaces for reverberatory copper-smelting and there was in process of erection an electrolytic refining plant, one of the first in the country.

In what year was that?

1883.

What pay did you receive?

\$60 per month as assayer. My experience at Ste. Genevieve proved valuable, for shortly after the copper plant was started I was able to help with the furnace work and without much delay was put in charge of the copper department of the smelter. From that time forward, while continuing to act as assayer, I was in direct charge of the reverberatory smelting and electrolytic refining under Mr. Barron.

How much was your pay raised on account of performing these additional duties?

At the end of two years I was receiving \$125 a month.

You evidently made a good start and attained a position of responsibility in a short time. You must have enjoyed your work?

I did enjoy it. It was no eight-hour day; all the time was full of interest as well as work. Samuel A. Barron, who was then superintendent of the plant, has retired and is living now in Los Angeles. George D. Barron, his brother, was book-keeper at the plant and left for Mexico shortly before I went to Leadville. He is now living near New York City and is one of the directors of the American Institute of Mining and Metallurgical Engineers.

How long were you at this smelter?

About two years and a half.

Why did you leave?

Because of an opening at Leadville, Colorado. In December 1885, I went to Leadville with Charles M. Donaldson, who had just been made manager of the Small Hopes mine, then in bonanza and one of the great mines of the district. My first duties were those of ore-sampler. All the ore from the mine was shipped to the local smelters or to those at Pueblo and Denver. The sampling was done in Leadville. There I got into numerous discussions as to the accuracy of the sampling, which was rotten. Improvements were gradually introduced. The Small Hopes was then in rich ore, in places almost massive silver chloride. Some of the most beautiful specimens I ever saw came from this property at a depth of 200 feet. These were tempting to the ore-thieves, and after a few months investigation it became clear that there was a well organized system of stealing. A number of the thieves were sent to the penitentiary and many more were driven out of the district.

You must have become manager of the mine soon, because I remember meeting you at the Small Hopes and being taken underground by you, in September or October of 1886, I think.

I remember very pleasantly our numerous meetings in Colorado. I may have been temporarily in charge at the date you fix, but I was not made manager of the property until the summer of 1887. Mr. Donaldson left to take charge of the Eureka & Excelsior property near Baker City, Oregon. The financial group that controlled the Small Hopes, namely, R. C. Kerens, James G. Blaine, Senator Elkins, Senator P. B. Plumb, H. B. Denman, and Major Hood, most of whom were then active in politics, had purchased the Eureka & Excelsior; and Mr. Donaldson had received a letter saying that they wanted him to take charge of one mine and me to take charge of the other. Being a very young man, I told Mr. Donaldson that I would be glad to accept either one, and he chose to go to Oregon.

Well, Mr. Mudd, you were extremely fortunate, for I happen to know the career of the 'E. & E.', as it is called in Oregon, as well as of the Small Hopes. How long were you manager of the latter?

I was on the payroll of the Small Hopes for 25 years.

When did the mine cease operations?

The bonanza ore was exhausted in 1887. Thereafter more complete exploration followed and the old stopes were worked over and over as decreasing smelting charges and improved economic conditions generally made possible the shipment of low-grade ores. To bolster up the declining profits of the company, leases on other territory were secured, and for many years the exploitation of leased ground was by far the more important part of our work. The Small Hopes Consolidated Mining Company sold its property in 1912 to a local syndicate, which operated it for a time and then sold it to the Empire Zinc Company.

Then the Small Hopes became more important as a producer of zinc than of silver?

WASHINGTON UNIVERSITY, ST. LOUIS

The production of zinc has not been large.

How much lead and silver did the Small Hopes produce?

It was not a large producer of lead, most of the ore being 'dry'. The net profits of the company were between three and four million dollars. The gross yield from the smelters was between six and seven million dollars. During the bonanza period the total cost at the mine, exclusive of smelting, amounted to less than 15% of the amount received in settlement with the smelter.

What was the grade of ore during the bonanza period?

From 60 to 80 oz. per ton, as an average.

How would you compare the type of miner you employed at Leadville 35 years ago with those that you find now, for instance, at Oatman or even at Leadville?

When I went to Leadville, the miners at the Small

Hopes were over three-quarters Cornish, with mining in their blood for generations. No better miners have ever existed. Gradually the percentage of the Cornishmen decreased and we got an increasing number of Americans and Irishmen. They too were excellent men after they had obtained the requisite experience. In Leadville most of the mining is done now by Austrians and Scandinavians, who usually are hard workers, but are not the equals of their predecessors in skill. I got so I could understand the Cornishmen fairly well, but with the Austrians and Finns the difficulty of language was insurmountable at times.

Will you say something about what is called the labor question?

The specific demands and immediate aims of labor today differ from those of the past, but human nature

LONGITUDINAL SECTION OF THE UTAH COPPER MINE

changes slowly and the present feelings of the laborer and capitalist are quite similar to those of the days gone by. Daniel Webster in 1833 described with remarkable accuracy the labor agitator and the feeling of unrest as they exist today. Labor has become dominant during recent years; it has grown so arrogant and unreasonable that the sympathy of the mass of the people is swinging away from the unions. Great power is dangerous and few have self-control, sanity, and tolerance enough to use it discreetly and well. Capital is apparently more sympathetic and just than ever before, partly at least because of necessity, and if the agitator who is disloyal to his country and intolerant of all difference of opinion can be deprived of his influence a speedy readjustment to a reasonable degree of harmony should take place notwithstanding the slackening industrial activity that is ahead of us. Intolerance of different races, of the followers of various religions, of the ambitions of different peoples and factions have caused most of the wars in history. Intelligent and sympathetic toleration of the viewpoint of the other side would soon draw labor and capital together, and would bring to our people a wonderful period of happiness and prosperity.

With what other properties were you connected at Leadville?

I was manager of the Leadville Consolidated Mining Co. and of the Boreel Mining Company for many years, and for a few years I was manager of the Ibex Mining Company, controlled by John F. Campion, A. V. Hunter, George F. Trimble, Eben E. Smith, and others. The Ibex mine was not only very rich, having produced more than any other Leadville property, but the ore occurrence was unusual and extremely interesting. I started leasing in a small way a few years after going to Leadville, and thereby became familiar with various parts of the Leadville district.

To engage in leasing is a good way of acquiring knowledge concerning a mining district.

Francis T. Freeland, whom you remember, used to say that Robert B. Estey and I started the plan, which has since become very common in the Leadville district, of leasing numerous tracts of contiguous ground and operating them as a unit. My first venture of this sort with Mr. Estey was started in 1893, when, after long negotiations, leases were secured from various owners on a number of pieces of ground at the east end of Fryer Hill. There was some question as to the title of parts of this ground and in one instance it was arranged between the two contestants that the royalty from any ore shipped should be held in trust until eventually through litigation it could be determined to whom it belonged. This operation was carried on under the name of the Union Leasing & Mining Company. Shipments were quite large for several years, up to 1897 or 1898. Without co-operation it was impracticable for any of the owners of small acreages to operate in that locality because of the amount of pumping that was necessary, but with control of a considerable area the operation became feasible.

What caused you to leave Colorado?

In 1887 I was married to Della Mulock. In 1901 we left Colorado on account of the health of one of our children, moving to Los Angeles, California. For two or three years thereafter I spent a good deal of time in Colorado, but gradually drew away from that State to the Pacific Coast.

What new mining ventures or professional work engaged your attention on this Coast?

For several years after moving to Los Angeles, I spent more than half my time in Colorado, in connection with the mining operations at Leadville, and also in connection with the work of the Empire Zinc Company, for which I acted as consulting engineer from 1902 to 1904. This branch of the New Jersey Zinc Company was under the local control of W. C. Wetherill, one of the finest and most charming of the older generation of engineers, and J. H. Troutman, who had been with the company for many years. This was to me a very pleasant association. The late W. C. Wilkens was in charge of the mining work for the company at that time and I got to know him intimately, to my great pleasure and advantage.

You got your first capital, I presume, by saving your salary and then by small participations with your principals?

No, not exactly. I saved from my salary and commenced to lease with Mr. Estey and others in Colorado. Before leaving Colorado I had acquired enough so that when I was offered the position of consulting engineer on the Pacific Coast for the Guggenheim Exploration Company I chose to have no salary but a rather larger compensation for anything that might be found.
